13th Annual Congress of the
EUROPEAN COLLEGE OF SPORT SCIENCE
9-12 July 2008, ESTORIL - Portugal

BOOK OF ABSTRACTS

Edited by:
Cabri, J., Alves, F., Araújo, D., Barreiros, J., Diniz, J., Veloso, A.

Hosted by:
Faculdade de Motricidade Humana
Universidade Técnica de Lisboa
Portugal
## Organisation

### Honorary Presidency
- Rector of the Universidade Técnica de Lisboa
- Mayor of the City of Oeiras
- Mayor of the City of Cascais
- Secretary of State of Youth and Sports

### Congress Presidency
- Luís Sardinha, POR, Congress President
- José Alves Diniz, POR, Chair Local Organizing Committee
- António Veloso, POR, Co-Chair Local Organizing Committee
- Jan Cabri, POR, Chair Local Scientific Committee
- Francisco Alves, POR, Chair Local Scientific Committee

### Congress Manager
- Maria Machado, POR

### Local Organizing Committee
- Isabel Morais, POR
- Marisa Costa, POR
- Ana Faria, POR
- Catherine Hutsemékers, POR
- Magdalena Kots, AUT
- Susana Pina, POR
- Porfírio Trincheiras, POR

### Local Scientific Committee
- Jan Cabri, POR
- Francisco Alves, POR
- Duarte Araújo, POR
- João Barreiros, POR
- José Diniz, POR
- António Veloso, POR

### ECSS Executive Board
- **President:** Albert Gollhofer, GER
- **President-Elect:** Hans Hoppeler, CH
- **Past President:** Erich Müller, AUT
- **General Secretary:** Sigmund Loland, NOR
- **Treasurer:** Romain Meeusen, BEL

### ECSS Scientific Board
- **Chair:** Tom Reilly, GBR
- **Co-Chair:** Anton Wagenmakers, GBR
- Peter Bärtsch, GER
- Flemming Dela, DNK
- Werner Helsen, BEL
- Paavo Komi, FIN
- Gertrud Pfister, DEN

### ECSS Scientific Committee
- Natalia Balague, ESP
- Jan Cabri, POR
Welcome

The European College of Sport Science (ECSS) welcomes you to Estoril for its 13th Annual Congress. Hosted by the Faculdade de Motricidade Humana of the Universidade Técnica de Lisboa, the ECSS is delighted to stage this major event at the wonderful and sunny coast of Estoril from 9 to 12 July 2008.

The 13th Annual Congress of the ECSS aims to provide an international forum for the presentation and discussion of the latest research in sports science and its related fields. The panel of distinguished scholars who are invited to share their expertise with the members of the scientific and professional community will, without any doubt, prove invaluable to its success.

The Scientific Programme is composed of more than 1,700 abstracts, which were accepted after being carefully reviewed. This year’s Congress is the largest in the history of the ECSS, underlining both the interest of the sport scientific community and the importance of the ECSS as an interdisciplinary forum for ongoing debate. In view of the multifaceted character of sport science, state-of-the-art presentations cover basic and applied sciences as they relate to sport, exercise and health. The presented abstracts comprise not only all relevant sub-disciplines of sport science but also all continents and 68 different nations. The abstracts are distributed among 4 Plenary Sessions, 36 Invited Symposia, 74 Thematic Sessions and 3 Poster Sessions, each presenting close to 400 Posters.

The choice of venue of the 13th Annual Congress of the ECSS shall provide you with a unique opportunity for either revisiting or an unforgettable first-time experience of the magic of Portugal.

On behalf of the ECSS we wish you all a very pleasant and productive stay in Estoril and hope that it will be both scientifically and socially successful.

José Alves Diniz

Chair Local Organizing Committee, Dean of the Faculdade de Motricidade Humana

IS-BN01 Propulsive forces in water sports

APPLYING TECHNOLOGY TO OPTIMISE SWIM-TRAINING: A LOOK IN THE (NEAR?) FUTURE

Toussaint, H.
Vrije Universiteit Amsterdam, University of Applied Technology, Netherlands

Peak performances in sport require the full deployment of all powers an athlete possesses. The development of those powers require years of hard training. It may be argued that training-time will be especially efficient when devoted to the enhancement of those performance factors that are weak links in the individual performance chain. Developments of measurement technology (with special reference to the MAD-system) have aided the sport scientist in identifying several factors as determinants of performance. These include drag, propulsion technique, and mechanical power (2). The development of this knowledge provides the modern coach with some guide-lines how to design training programmes. However, it may be argued that training-time will be especially efficient when devoted to the enhancement of those performance factors that are weak links in the individual performance chain. This implies that on an individual level it is necessary to identify in what phase of the process the performance system first becomes insufficient. Those factors when improved would immediately contribute to overall performance and, consequently, training time allotted to these factors would be well spent.

In the training process it is rather challenging for coaches to determine which training load is sufficient to induce the required adaptation without risk of overtraining. More insight in the individual relation between training dose and adaptation response is necessary to optimise this training process. Training dose and changes in performance capacity can be modelled (1). In this model performance is a systems output varying over time according to the systems input; the training dose or training impulse (TRIMP), quantified from exercise intensity and volume. The subject is represented by a system with a daily amount of training as input and performance capacity as output.

In this paper a sketch will be given how, by the application of new technology developed in close cooperation with industry, training characteristics can be linked to improvement in performance such that optimization of the training process becomes possible.

DERIVING THREE-DIMENSIONAL FORCES AND TORQUES IN SWIMMING

Sanders, R.
The University of Edinburgh, United Kingdom

Forces and torques changing the motion of humans performing sport skills can be transduced directly or can be derived from kinematic data. Measuring forces and torques acting on free swimmers directly, and in a manner that doesn’t affect the performance, is complicated by the swimmer moving at the interface of two fluids, air and water, rather than being in contact with a solid supporting surface.

The purpose of this presentation is to describe methods by which net three-dimensional (3D) forces and torques acting on swimmers can be derived from digitised position-time data and to provide examples of how those methods can yield original insights into swimming performance. Prior to the presentation of original and interesting findings the methods will be briefly outlined. These include the marking of swimmers to define a full segmented body model, obtaining body segment parameter data including segment masses and centre of mass locations relative to segment endpoints, and segment moments of inertia using the ‘Elliptical Zone’ method; calibrating the 3D space, simultaneous recording by multiple underwater and above water cameras; transformation of the calibration and body markers digitised from each camera into 3D position-time data using the direct linear transformation (DLT) technique; and calculation of the net force components and torques about the three principal axes using a bespoke MATLAB program. The methods enable fresh insights into the mechanisms of propulsion in swimming, the contributions to body roll, and the influences of the forces and torques on the timing and rhythms of the swimmers’ linear and rotational motions.

COMPUTATIONAL FLUID DYNAMICS: A FUNDAMENTAL TOOL FOR SWIMMING RESEARCH

Silva, A., Marinho, D., Reis, V., Alves, F., Boas, J., Machado, L., Rouboa, A.
University of Tras-os-Montes And Alto Douro, Portugal

Introduction

Swimming hydrodynamics has been studied since long with experimental tests and recently with numerical techniques using Computational Fluid Dynamics (CFD) models (e.g. Silva et al., 2008). The aim of this work was to present the already applied CFD techniques and to suggest new procedures that may be used by the research community in further studies under similar research topics.

Methods

The CFD methodology consists of a mathematical model applied to the fluid flow in a given domain that replaces the Navier-Stokes equations with discretized algebraic expressions and solved by iterative calculations. This domain consists of a grid or mesh of cells that simulate the fluid flow around physical structures. The boundary conditions were considered and implemented in the CFD commercial code Fluent®. In order to be able to simulate the fluid flow, models of the human body were used. Whole human body models were
used to analyse the hydrodynamic drag while the hand and forearm models were used to analyse the upper arm propulsion during swimming.

Results
Regarding the studies involving the hydrodynamic drag it was found that: (i) in a drafting situation the drag of the back swimmer increased with the distance between swimmers and at a 0.50 m distance the drag of the back swimmer was around 50% of that of the front swimmer, (ii) during the gliding after the starts and turns, the position with the arms extended at the front presented lower values of hydrodynamic drag (60%) than the position with the arms along the trunk. Regarding the upper arm propulsion, it was found that: (i) the hand/forearm drag was the coefficient that accounts more for propulsion, (ii) the coefficient of lift seemed to play a residual influence in the generation of propulsive force by the hand/forearm segment at angles of pitch of 0° and 90°, but it is important with an angle of pitch of 45°, (iii) under the accelerated flow conditions the hand/forearm models presented higher values of drag and lift coefficients than under the steady flow conditions.

Conclusion
The recent evidence suggests that the CFD technique can be considered an interesting new approach for hydrodynamic forces calculation in swimming, providing valuable considerations for defining new swimming techniques and other flow fields.

IS-SH01 Challenges on children sport

PREVENTING GLOBAL VIOLENCE TO CHILDREN IN SPORT: RESEARCH FROM UNICEF
Brackenridge, C., Fasting, K., Kirby, S., Leahy, T.
Brunel University, United Kingdom

UNICEF’s mission is to advance humanity for every child through health, education, equality and protection. In order to establish an evidence base for its work, the Secretary General of the United Nations, through UNICEF, commissioned a global study of violence against children, which was published in 2006 (hereafter The UN Study). This presented details of the nature, extent and causes of violence against children, and proposed recommendations for action to prevent and reduce such violence. Barring one small reference, sport did not featured in this study, perhaps for the very good reason that it was not perceived as a social or economic priority. But UNICEF has demonstrated an awareness of the importance of sport in the lives of young people and an enthusiasm for incorporating sport-related items into its policy recommendations. Its own work in the field of sport has focused largely on two functions: sport as a mechanism for fund-raising and sport-for-development in developing countries and post-conflict reconstruction. Interestingly, in neither arena has UNICEF’s own commitment to children protection been strongly in evidence. In order to start redressing this, UNICEF’s Innocenti Research centre in Florence hosted an expert panel on sport and violence to children in May 2008 which led to two research projects. These projects are intended to develop a set of proposals about both the potential of sport for reducing violence to children through sport and also the importance of safeguarding children within sport.

The first project comprised systematic review of the published research and policy material on violence and abuse to children in sport. It will appear in mid 2008 as a UNICEF Digest which defines and presents the evidence base for different types of violence to children in sport, and reviews the policies and programmes that have been instituted to tackle these problems around the world. The Digest concludes with a list of geographic and knowledge gaps that were identified through the research and a set of measures related to these gaps that require future action.

The second project comprised a secondary analysis of all the supporting documents collected for the UN Study. The results will appear in an Innocenti Research Centre Working Paper in 2008. One part of the analysis focused on surveys returns for the UN Study from each of 122 countries and scanned these for mention of sport, sports policy and sport programmes for violence prevention. Interestingly, the returns from those countries known by the researchers to be the most advanced in terms of child protection and violence prevention in children’s sport did not reflect this. Thus, a communication gap was exposed between governments and sport NGOs in these countries. The presentation will discuss the findings from these two studies and suggest a number of future directions that this work might take.

BULLYING IN YOUTH SPORT
Fasting, K., Sisjord, M., Roberts, G.
Norwegian School of Sport Sciences, Norway

Over the last few years there has been increasing interest in and research on the problem of bullying. The previous research has been conducted primarily in schools, with very little conducted in sport settings. The few studies that exist focus on hazing and initiation rites, which may include bullying. The purpose of this paper is to present the experiences of being bullied among young Norwegian athletes. In the school context, some Norwegian studies have shown that boys are bullied more in schools than girls, and that boys and girls experience different forms of bullying. The research has revealed that the bullied child often is perceived as vulnerable and ‘different’. The main questions asked in this paper therefore are: what is the amount of bullying experienced by young people in a sport setting, are there any gender differences between girls and boys in their experiences of bullying in sport; do youths with non-western immigrant backgrounds experience more bullying than other youths; and what forms of bullying do they experience?

Participants in the study were 1514 Norwegian youths 12-16 years of age (males n=917, [M=13.5], females, n=597, [M=14.1]) competing in eight all- or multi-sport teams and individual sports in and around the greater Oslo area in Norway. The participants were asked if they had experienced any of the following three types of unpleasant behaviours: ridicule, being called nasty names or teased in an unpleasant and hurtful way being beaten, kicked, pulled by the hair, pushed or locked up being excluded or ignored. For each of these questions, they were asked if they had experienced it from a male or female coach, and/or from male peers or female peers in sport.
The analyses showed that 27% of the young people participating in this study had experienced one or more of the unpleasant behaviours from someone in sport. A chi square test revealed no statistically significant difference between boys and girls. In analyzing the three questions separately however it turned out that significantly more girls than boys were ridiculed and teased etc., but that significantly more boys than girls had experienced being excluded or ignored. The last category was the one that most often had happened to the participants (19%), followed by ridicule and teasing (15%), while only 5% had been beaten or kicked etc. Youths with a non-western immigrant background had more often experienced bullying (32%) compared with other youths. This difference was however significant only for the two first forms of bullying (ridicule and being beaten).

The results are discussed in relation to studies from bullying in other settings, such as in schools, and in relation to gender theories.

MONITORING PARTICIPANT GROUP CONDUCT IN YOUTH SPORT: THE JUSTPLAY BEHAVIOUR MANAGEMENT PROGRAM

Raakman, E.
Justplay Sports Services, Civic Sport Group, Canada

The Justplay Behaviour Management Program (henceforth the BMP) has been collecting data regarding the conduct of players, coaches and spectators, on a game by game basis for sports such hockey, soccer, football, basketball and baseball for seven years. The data is input by officials via the internet where it is organized and displayed as a library of graphs available 24/7 to sport administrators of each member organization. The library of graphs allows administrators to make data-driven staffing and policy decisions necessary to anticipate, respond or avoid problematic behaviour of players, coaches and spectators. Monthly reports are provided to administrators which highlight both positive and negative trends in participant group behaviour, as well as, an analysis of which factors are most positively or negatively affecting official ratings and official satisfaction.

Importantly the BMP yields important feedback to administrators regarding the effectiveness of initiatives implemented to resolve or respond to identified problems. For example many member organizations with persistent behaviour/conduct concerns have submitted their behaviour policy to Justplay for a review and analysis. Using the data, the summary reports and comments provided by officials we are able to determine precisely which elements of policy are consistently violated, and therefore ineffectual. At this point we work with the organization to help develop policy and behaviour standards that they support and enforce. With the information gathered from the BMP, success is easily monitored.

Over the past couple of years Civic Sport Group has used the Justplay BMP to collaborate on a number of research projects, some of which are on-going. The volume of data in the system, the diversity of sports and geographical areas in which we are working (and able to work), the ease of data collection and analysis, as well as, the ability to correlate/contrast the data with official data and socioeconomic markers combine to make the BMP a valuable research tool. Recently we adapted the program to collect data from the players (children). In an effort to examine ‘bullying’ in the hockey environment we had players ages 8-18 fill out an on-line card following every game. Children could do this in the privacy of their own home, under the supervision of their parents if necessary. In November 2007 we began another project which focuses on studying the factors which contribute to official’s satisfaction. The presentation will consist of a brief demonstration of the BMP, followed by a discussion of program applications and research results of the above mentioned projects.

Invited symposia (IS)

IS-SH02 Physical Education and Teacher Preparation - Present and Future

THE FUTURE OF PHYSICAL EDUCATION AND TEACHER PREPARATION

Fisher, R.
St. Mary's University College, United Kingdom

Looking to the future is an exciting but dangerous undertaking, in education as in any other sphere of life, and history is replete with examples of predicted trends that never materialised or did so in completely unanticipated ways. It is wise then to be cautious but, given the ongoing pace of social change, important nonetheless to identify major socio-political trends and attempt to anticipate what the consequences might be for education in general and teacher education in particular. The first requirement is to acknowledge the nature of social change itself and it is clear that, at least in so-called advanced industrial countries and those that have experienced major political change, competitive market forces, increasingly complex economic structures and pressure on public services are driving increased de-centralisation, a stronger role for the private sector and a more critical clientele, be that parents or young people.

At present countries are engaged with large scale building reforms in education, for example England and Wales and Portugal, which has prompted interesting discussions about a suitable framework for how the future might look, how schools will function, what building designs are appropriate and what parents will require and pupils engage with. However, the extent to which those discussions have been radical enough is open to question. The Teaching 2020 project in the UK (www.teachernet.gov.uk) highlighted such things as the need for more flexible curricula for increasingly ‘disorganised environments’, greater emphasis on the learning process than factual knowledge and the growth of learning as a community enterprise; the teacher functioning at the core of a learning network involving the local community, business and parents. Indeed, with the future power of home technology, ever more selective parents and substantial growth in the private offer in education there are questions about whether all pupils need to attend school all the time anyway where would that leave physical education? In fact the physical education curriculum in many schools persistently remains a fairly traditional offering that often fails to acknowledge such things as young people’s lifestyle interests, so the subject has some interesting challenges.

Teacher education is challenged no less by these possible future scenarios. As the state increasingly disengages with the public sector, provision of a national framework and base-line provision only for initial qualifications with the rest, including continuing professional development, being employer driven, learner directed and locally provided gathers pace. Universities will come under greater challenge from the private sector and institutions in other countries to remain major players in this field, are they ready for it?
RESEARCH ON TEACHING IN PHYSICAL EDUCATION: PRESENT SITUATION

Carreiro da Costa, F.
Technical University of Lisbon, Portugal

As for the concept of “research on teaching in physical education” there is not in the literature a consensus about what is its object and problematic. As a consequence, when we talk about research on teaching in physical education first of all it is important to clarify its meaning. We share the perspective that research on teaching is the process that investigates educational facts and educational interactions, specifically the teachers and students’ beliefs, attitudes and their cognitive and thinking processes, the teachers and students’ actions and interactions within the pedagogical relationship, and the effects of the pedagogical activity on the social dynamics of the class, and on the students’ learning process and development. Research on teaching also analyses the values, goals and curriculum ideology underlying a physical educational programme, and how PE teachers’ adapt curriculum and transform subject matter for teaching. Furthermore, research on teaching PE investigates the influence of the organizational, social, and cultural contexts on the dynamics of educational situations. Taking into account that research on teaching is not a free value activity, firstly we will make reference to the conceptual and methodological references which have framed and guided research on teaching in physical education. Secondly, we will analyse the following research programs: (a) the study of teaching effectiveness; (b) the study of the teachers’ thinking processes and actions; and (c) the study of the cognitive, socio-affective, and motor mediating processes of the PE students’ participation. We will make a brief reference to the main purposes, themes, and methodologies used by each of those research programs. Thirdly, we will make reference to the study of ecology in teaching physical education, an emerging conceptual approach that has shaped a growing number of studies. We will end up the intervention talking about the main trends of the current research on teaching in physical education. In asserting that no single paradigm can capture the complexity of educational events, we will mention the paradigm eclecticism and the problems that have received more recent attention from researchers. To better illustrate these concerns, we will present some examples of studies that have been carried out.

CURRENT TRENDS IN THE RESEARCH ON PHYSICAL EDUCATION TEACHER EDUCATION (PETE)

Cloes, M.
University of Liege, Belgium

In several countries, teacher education programmes have integrated a competency centered approach based on official recommendations aiming to prepare more professional teachers. The latter are defined as (Brau-Anthony & Grosstephan, 2006, p.93):
- having a knowledge basis;
- assuming a mission of knowledge transmitter;
- being able to act in emergency and to decide in uncertainty;
- being able to think about one’s teaching and to analyse it;
- showing autonomy and responsibility;
- having a professional ethics compatible to the values of the public educational service.

The first part of the paper will compare the guidelines proposed by educational authorities in some countries or regions in order to identify the main similarities. Moreover, it is well accepted that teacher preparation is a long term process during which this large array of competencies should be progressively developed (Calderhead, 2000; O’Sullivan, 1998). In their process of development from the beginner level to the expertise, educators draw experience from a diversity of learning contexts allowing them to acquire personal and professional competencies that will help them to succeed in their classes. The second part of the paper will be focused on that process. After a description of the long life model of development, opinions of teachers about the importance of the competencies and where they are developed will be analysed. Despite the emphasis to develop inductive approach aiming to help student teachers to acquire analysis skills and to build their own intervention models, it appears that teacher education remains dominated by deductive approach using a “traditional” model. Following this, specific teaching behaviours are selected and presented in teacher training courses before being experimented during teaching practice.

The third part of the paper will present some selected studies illustrating strategies tested all around the world in order to innovate and getting closer to the learning society characteristics (Jarvis, 2007).

OP-BN01 Biomechanics 1

THE ANALYSIS OF PRESSURE DRAG AND SKIN FRICTION DRAG DURING THE GLIDING IN SWIMMING

1: UBI (Covilhã, Portugal), 2: UTAD (Vila Real, Portugal), 3: CIDESD (Portugal), 4: FMH-UTL (Lisbon, Portugal), 5: FADEUP (Porto, Portugal).

Introduction
In human swimming, the total drag is composed of the skin friction drag, pressure drag and wave drag. The relative importance of each component to the overall hydrodynamic drag is a controversy issue. Therefore, the aim of this study was to analyse the relative contributions of the skin friction drag and the pressure drag for the total drag during the gliding, using numerical simulation techniques.

**Methods**

The numerical simulation analysis consisted of the use of a three-dimensional mesh of cells that simulates the flow around the considered domain. We used the k-epsilon turbulent model (Moreira et al., 2006) implemented in the commercial code Fluent® and applied to the flow around a three-dimensional model of a male adult swimmer in a gliding situation, in ventral position with the arms extended at the front. The simulations were applied to different flow velocities, between 1.6 m/s and 2.0 m/s and the coefficient of drag (CD) was computed to each one of the applied velocities. Moreover, the CD was decomposed into pressure and skin friction drag by Fluent® software.

**Results**

Velocities of 1.6, 1.7, 1.8, 1.9 and 2.0 m/s produced, respectively, CD values of 0.48, 0.475, 0.432, 0.431 and 0.428. The pressure drag was the main responsible for the total drag, with a percentage of about 87%, while skin friction drag contributed to about 13% for the total drag during the underwater gliding.

**Discussion**

In both gliding positions the swimmer CD decreased with the velocity. The inverse relationship between the CD and the velocity found in the present study seems to correspond to what happens in experimental situations in the human body totally submersed (Jiskoot and Clarys, 1975; Lyttle et al., 2000). Our research was limited to the influence of the pressure drag and the skin friction drag in the total drag coefficient since the swimmer model was placed 0.90 m under the water surface (Lyttle et al., 2000).

The computed drag forces components showed that the pressure drag was dominant. Nevertheless, skin friction drag was by no means negligible. However, these values are based on the swimmer model’s surface having a zero roughness. Another different situation could happen if the swimmer were at the water’s surface. The contribution of the skin friction drag would be reduced due to the reduction in the wetted area and the generation of wave drag (Bixler et al., 2007).

**LOCOMOTOR ADAPTATION RELATED TO PREDICTIVE AND FEEDBACK STABILITY CONTROL STRATEGIES WHILE PERTURBATIONS IN YOUNGER AND OLDER ADULTS**

Bierbaum, S., Karamanidis, K., Peper, A., Arampatzis, A.

German Sport University Cologne, Germany

Postural corrections after unexpected perturbations involve reactive sensorimotor strategies to maintain the dynamic stability of the human system. However, posture is not a static state but can be modified on the basis of feedforward (predictive) as well as feedback adaptive improvements of postural behaviour when perturbations occur. Especially for the elderly, successful postural corrections based on both predictive and feedback stability control strategies during perturbations may be vitally important because falls are the major cause of injury among the elderly population. Although some studies have previously demonstrated an age-related decrease in recovery performance after unexpected perturbations, there is no information about the age-related adaptive responses in the components of dynamic stability during the incidence of repetitive perturbations. Therefore, the purpose of this study was to examine the age-related predictive and feedback adaptive locomotor improvements of dynamic stability control during disturbed walking. Older (62-74yr) and younger (23-30yr) subjects performed walking in a given speed. The gangway included one exchangeable element which was not visible for the subjects. This allowed the replacement of the element to change the surface stiffness (hard/soft). The gait-protocol comprised 23 trials with soft and hard surface, arranged to detect predictive as well as feedback strategies over the repetitions.

Motion capturing system was used to determine the subject’s 3D-kinematics and ground reaction forces, respectively. Components of dynamic stability while walking were calculated according to Hof et al. (2005). Compared to base line walking both age groups increased the margin of stability at touchdown (TD) at the disturbed leg within the gait repetitions (old: -7.3±3.8 to -4.4±4.2cm, young: -11.8±4.7 to -8.2±3.3cm) by increasing the base of support at the step before the perturbation. Even though these anticipatory adjustments were performed by both age groups in a similar manner in order to reduce the consequences of the perturbation, the older participants needed more repetitions to increase the base of support. In the step after the perturbation the margin of stability at TD decreased in both groups (old: -8.4±3.9cm to -19.6±7.5cm, young: -12.8±5.2cm to -16.2±8.3cm) but stabilised after 2 to 4 repetitions to the base line values. In the first disturbed trial the older adults showed a higher decrease in margin of stability at TD after the perturbation due to a lower increase in the base of support compared to the younger ones. Concluding, both age groups showed similar predictive as well as feedback adaptive improvements during the adaptive changes, however, happened in younger adults faster compared to the older ones.

MUSCLE FASCICLE STRETCH VELOCITY IN RELATION TO STRETCH REFLEX ACTIVATION AT DIFFERENT CONTRACTION LEVELS IN HUMAN TRICEPS SURAE

Cronin, N., Peltonen, J., Ishikawa, M., Avela, J., Komi, P., Sinkjaer, T., Voigt, M.
Aalborg University, Denmark

Stretch distribution between muscle and tendinous tissues depends on their relative stiffnesses. At low forces, most of the stretch occurs in the more compliant muscle fibres. However, muscle and tendinous tissues both become stiffer with increasing force, with a greater relative increase in the muscle fibres. As muscle spindles only ‘see’ the movement of the muscle fibres in which they are situated, their view of a stretch depends on its distribution between muscle fibres and tendon. The aim of this study was to examine changes in stretch distribution to muscle fascicles with changes in contraction intensity in the human triceps surae. This information was related to EMG reflex responses.

Thirteen healthy subjects aged 21-30 participated. Subjects sat in an ankle ergometer with the ankle (90°), knee (180°) and hip (120°) angles fixed. Dorsiflexion stretches of 8° were applied at a velocity of 250°/s to the ankle at different contraction levels: 0, 20, 40, 60, 80 and 100% of MVC. Surface EMG was recorded in the medial gastrocnemius (MG), soleus (SOL) and tibialis anterior (TA) muscles. Fascicle lengths of MG and SOL were determined using ultrasound.

In both muscles, reflex amplitudes peaked between 40-60% and declined thereafter. Between 0 and 100%, pre-stretch fascicle length decreased by 1.80cm and 0.86cm in MG and SOL, respectively. In addition, fascicle stretch amplitude decreased by 57% and 53% and fascicle stretch velocity decreased by 61 and 56% in MG and SOL, respectively.

Stretch distribution was modulated with variations in contraction level, and the velocity at which muscle fascicles stretched dramatically decreased at high forces. As stretch velocity is more potent to muscle spindles than stretch amplitude, and assuming constant sensitivity of the muscle spindles to stretch velocity, this decline would decrease afferent activity, contributing to the decreased reflex response. Short latency reflexes play an important role in force3 and stiffness production4, so the decrease in reflex stiffness we have observed previously at high contraction levels5 can at least partly be explained by this observation.

THE EFFECT OF SHOE DESIGN ON REARFOOT KINEMATICS, KINETICS AND PLANTAR FORCES

Chuter, V., Smith, R.
University of Newcastle, Australia

Motion control components incorporated in the upper vamp and midsole design of shoes have been based on biomechanical reasoning which assumes excessive motion can be controlled via mechanisms of restraint. However, multiple studies have failed to provide unequivocal evidence to support this theory. Evidence of compensatory changes to kinematic gait parameters associated with alterations to density of the shoe sole suggests cutaneous afferents from the plantar surface of the foot may have an important role in the control of foot motion (Zhang et al., 2000). Several studies indicate altering cutaneous input may instigate a feed forward mechanism demonstrated by an alteration to kinematic function and muscle activity prior to heel strike (Wakeling et al., 2003). This study investigates the effect of five different styles of shoe on walking and running gait and examines possible relationships between footwear design factors, plantar force distribution and rearfoot kinematics and kinetics. Three dimensional lower limb kinematics including in-shoe rearfoot motion, ground reaction forces (GRF) and plantar forces were collected for 16 subjects in each condition.

Increased stiffness of the shoe and dual density midsoles were found to increase inversion angle at heel strike compared with a barefoot condition and neutral and flexible shoes (p<0.004). Significant increases in mean force (p=0.001) and the force-time integral (p<0.001) under the lateral aspect of the calcaneus in the dual density condition supports the finding of a more inverted heel strike angle. This is further substantiated by increases in medial calcaneal mean force and force-time integral in the most flexible shoe condition which demonstrated the most everted heel strike angle. The dual density condition also demonstrated an increase in peak ankle joint inversion moment compared to other conditions suggesting that the more inverted position at heel strike induced a centre of pressure (COP) pathway closer to the long axis of the foot, reducing the evertor lever arm of the GRF. Running gait also produced an abduction moment in the dual density shoe which did not occur in other conditions and supports the medial location of the COP.

These finding indicate changes to terminal swing phase mechanics, suggesting footwear design has a significant non-mechanical effect on foot function. Changes to heel strike angle with specific shoe designs implies a feed forward mechanism is instigated by alteration to the foot-ground interface. This strongly supports a possible neuromuscular component to controlling foot function with footwear.

CAN HUMAN ACHILLES TENDON BE FATIGUED AFTER STRETCH-SHORTENING CYCLE EXERCISE?

Peltonen, J., Cronin, N., Finni, T., Oksanen, H., Avela, J.
Neuromuscular Research Center, University of Jyväskylä, Finland

When placed under continuous stress, tendons behave like elastic materials and can be fatigued. That is under deformation their ultimate strength (US) decreases. This fatiguing behavior of a tendon was first shown with wallaby tail tendons by Wang and colleagues (1995). Now question this study aims to answer is: Do human tendons fatigue after voluntary exercise?
Schechtman & Bader (2002/3) showed in a cadaver study that if US is decreased in human tendons after cyclic stretching, also linear relationship between stress and strain is decreased. This slope of the linear part of stress-strain curve is called Young's modulus of tendon. If Young's modulus of tendon is decreased after exercise, tendon is said to be more compliant. Evidence for increased compliance after voluntary exercise in humans has been previously presented by Kubo et al. (2001).

In this study, subjects (N=9, mean age, weight and height: 26y, 67kg and 172cm) underwent a hopping exercise using their ankle plantar flexor muscles. Exercise consisted on average 2000 (range: 1200-3000) jumps at preferred frequency until exhaustion. Before and after exercise, subjects performed a tendon stiffness test. In tendon stiffness test, subjects sat in ankle dynamometer (knee in full extension) and produced six isometric contractions with ankle plantar flexors: 100%, 80%, 60%, 40%, 20% and 100% of maximum voluntary contraction torque. Tendon displacement of Achilles tendon that is anchored to m. Gastrocnemius medialis and torque over ankle joint was recorded for each isometric contraction.

Data from axial and coronal magnetic resonance images was combined with tendon stiffness test data to calculate tendon stress and strain individually. Straight line, using least-squares method, was fitted to six pairs of values (stress vs. strain). Change in the slope of the line (Young's modulus) was a measure of tendon fatigue in this study. Tendon stress during maximum voluntary contraction decreased from 140±30MPa to 100±40MPa (P<0.01). Young's modulus, however, didn't change significantly. It reduced from 2.7±1GPa to 2.4±0.9GPa.

It's concluded that despite the fact that exercise was performed until exhaustion and induced reduction in maximum voluntary stress, there was no decrease in tendon stiffness and therefore no tendon fatigue. This is in agreement with previous studies that haven't found any changes in tendon stiffness after voluntary exercise (Maderni et al., 2006).

**CARDIOVASCULAR AND NEUROMUSCULAR RESPONSES DURING INTERMITTENT CYCLING EXERCISE PERFORMED WITH ELECTRICAL ASSISTED VERSUS CLASSICAL BICYCLE**

Theurel, J., Lepers, R.

Institut National de la Santé et de la Recherche Médicale (INSERM U887), France

**Introduction.**

In the current social and environmental context, electrical assisted bikes (EB) could become an interesting urban mode of travel. For example, EB has been recently used by postal agents during their delivery route. EB is supposed to reduce muscular and cardiovascular strains during postal work, in comparison with classical bike (CB). The objective of the present study was to compare the energetic and muscular responses during intermittent cycling exercise performed with EB versus CB.

**Methods.**

Ten subjects (age: 34±14 years) performed two intermittent cycling exercises, in a random order. Experiments were conducted either with EB or CB, which were adjustable to replicate identical positioning of subjects. Each exercise was performed with alternating cycling starts (10±60m) and rest period (20 s) for 30 min (i.e. 60 starts). Oxygen uptake (O2) and heart rate (HR) were continuously recorded, by gas exchange analyzer (K4b2, Cosmed, Rome, Italy), during exercise and averaged every 30 s. For each cycling start (S1 to S60), EMG was recorded and root mean square (RMS) was calculated for vastus lateralis (VL), rectus femoris (RF) and gastrocnemius medialis (GM) muscles of the right leg. Subject used a scale of rating perceived exertion (RPE) to judge their global effort (from 6 to 20) after 5, 10, 20 and 30 min of exercise.

**Results:**

Mean O2 was 30±20 % greater during CB than during EB session. O2 was greater with CB than with EB from the second start (29±3 vs. 24±6 ml-1.min-1.kg1) to the end of exercise (respectively 42±5 vs. 31±3 ml-1.min-1.kg1). Averaged HR was 20±17 % greater during EB than during CB session. HR was similar for both conditions after the first start (EB: 107±19 bpm vs. CB: 113±16 bpm), but differ significantly (p<0.01) from 2 min to the end of exercise (CB: 173±13 bpm > EB: 144±27 bpm). EMG RMS was constant from the beginning to the end of exercise for both cycling conditions and the three muscles. However, EMG RMS was respectively 44±30 %, 50±47 % and 40±38 % greater for VL, RF and GM muscles respectively, during CB than during EB sessions. Mean RPE was higher during CB than during EB session (15±2 vs. 11±2), reaching 17±2 at the end of EB session versus 11±2 at the end of EB session.

Discussion. The present data evidenced that EB cycling reduced energetic and muscular demand in comparison with CB cycling during intermittent exercise. Considering that cyclist distribution of postal mail is similar to an intermittent cycling exercise (Theurel et al. in press), these findings suggested that EB is an interesting tools to reduce physical strains of postal agents during their delivery route.

to have minor or no effects on HRV. This study examined the effects of combining endurance and strength training on HR measures and physical fitness. 94 men aged 40 to 67 years completed the 21-week progressive training period consisting of either 2 endurance (E), 2 strength (S), both 2 endurance and 2 strength (ES) training sessions per week or no systematic training (control group). Maximal oxygen uptake (VO2max) was measured during a graded cycling test until voluntary exhaustion. R-R intervals were recorded during a 5-min supine rest and a 5-min low intensity exercise (50 W) and analyzed by the spectral method from high (0.15-0.4 Hz) and low (0.04-0.15 Hz) frequency bands (HF and LF). Furthermore, fractal scaling properties of heart rate dynamics were analysed by the DFA method and expressed as a short-term fractal scaling exponent (alpha-1). Maximal bilateral leg extension strength (1RM) was measured using a dynamometer.

Endurance training showed different changes in resting HR and fractal scaling properties compared to strength training. However, when strength training was combined with endurance training the positive effects of endurance training on the cardiac autonomic function remained. These effects may be more evident with the DFA method than the frequency domain method of HRV in the present short term recordings. These results suggest that combined endurance and strength training improves both endurance and strength performance to the same extent compared to endurance or strength training alone without compromising the improvements in cardiac autonomic function.

EFFECTS OF STRENGTH AND ENDURANCE TRAINING ON METABOLIC HEALTH IN OLDER MEN

Sillanpää, E., Häkkänen, A., Punnonen, K., Häkkänen, K., Laaksonen, D.
University of Jyväskylä, Finland

Physical exercise is a cornerstone in the prevention of the metabolic syndrome and type 2 diabetes. However, the optimal type and intensity of physical exercise that should be used to maximize health benefits of exercise in decreasing metabolic risk factors is unclear (Johnson et al., 2007, Lakka & Laaksonen 2007). This study compared the effects of 21 weeks of combined high-intensity strength and endurance training with endurance or strength training only on metabolic risk factors in 40-65 years old men. 63 healthy men were randomized into the endurance (E), strength (S), combined strength and endurance training (SE) or control group (C). S and E trained 2 times a week and SE 2 times a week for strength and 2 times for endurance for 21 weeks. Heart rate monitored endurance training by cycling and total body strength training consisting of exercises for lower and upper extremities and trunk were utilized. Metabolic risk factors investigated were resting blood pressure, glucose and insulin metabolism by oral glucose tolerance test (OGTT) and blood lipids and lipoproteins. Body composition was measured by percentage of fat (skin folds) and waist circumference and physical fitness by maximal oxygen uptake (VO2max) during cycling and by isometric bilateral leg extension strength. After training both E (10%, p<0.001) and SE (11%, p<0.01) had increased VO2max significantly, but not S or C. Leg extension strength increased markedly in S (15%, p<0.01) and SE (17%, p<0.001), but less in E (8%, p<0.01) and not at all in C. Waist circumference decreased by 1.7-2.2cm in all three training groups and fat percent in all groups, especially in SE (from 24±5 to 22±4%). Systolic blood pressure (SBP) decreased significantly both in E (-6±8, p<0.01) and S (-9±8, p<0.001) and also diastolic blood pressure in E and S (-4±6mmHg and -5±7mmHg, both p<0.05), respectively. There were no changes in blood pressure in SE or C. A significant difference in the changes of SBP served in blood lipids and lipoproteins in all groups.

After training both E (10%, p<0.001) and SE (11%, p<0.01) had increased VO2max significantly, but not S or C. Leg extension strength increased markedly in S (15%, p<0.01) and SE (17%, p<0.001), but less in E (8%, p<0.01) and not at all in C. Waist circumference decreased by 1.7-2.2cm in all three training groups and fat percent in all groups, especially in SE (from 24±5 to 22±4%). Systolic blood pressure (SBP) decreased significantly both in E (-6±8, p<0.01) and S (-9±8, p<0.001) and also diastolic blood pressure in E and S (-4±6mmHg and -5±7mmHg, both p<0.05), respectively. There were no changes in blood pressure in SE or C. A significant difference in the changes of SBP served in blood lipids and lipoproteins in all groups.

After training both E (10%, p<0.001) and SE (11%, p<0.01) had increased VO2max significantly, but not S or C. Leg extension strength increased markedly in S (15%, p<0.01) and SE (17%, p<0.001), but less in E (8%, p<0.01) and not at all in C. Waist circumference decreased by 1.7-2.2cm in all three training groups and fat percent in all groups, especially in SE (from 24±5 to 22±4%). Systolic blood pressure (SBP) decreased significantly both in E (-6±8, p<0.01) and S (-9±8, p<0.001) and also diastolic blood pressure in E and S (-4±6mmHg and -5±7mmHg, both p<0.05), respectively. There were no changes in blood pressure in SE or C. A significant difference in the changes of SBP served in blood lipids and lipoproteins in all groups.

Both progressive endurance and heavy resistance strength training can modestly improve metabolic health even in relatively lean older men with normal glucose tolerance. Combined strength and endurance training did not produce complementary benefits on metabolic risk factors, but it is effective in improving both cardiorespiratory and muscular fitness as well as body composition, especially during prolonged training.

GENDER, AGE AND COGNITIVE SCORE EFFECTS ON STRENGTH IN SPANISH INSTITUTIONALIZED ELDERLY

Pedrero-Chamizo, R., Albers, U., Jiménez-Pavón, D., Perales, M., Meléndez, A., Castillo, MJ., González-Gross, M.
Universidad Politécnica de Madrid (Spain) and Universidad de Granada (Spain), Spain

Introduction: Physical strength is one of the most important physical capacities in old people since maintaining optimal strength values will allow autonomous lifestyles during longer time. Little information is available about functional fitness parameters in institutionalized elderly.

Aim: To analyze muscle strength of hands, arm and legs in Spanish institutionalized elderly according to gender, age groups and cognitive score.

Material and methods: One hundred and twenty six elderly, 47 men and 79 women, participated in a cross-sectional study. Mean age was 81±8 and 84±6, respectively. All subjects were institutionalized living in Madrid (Spain). Hand grip strength (kg) was measured with a Takei TKK 5101 digital dynamometer (range 5-100 kg, precision 0.1 kg). Arm strength (rep/30s) and chair stands (rep/30s) were used according to the Rikli and Jones test. Cognitive status was determined using the Mini Mental State Examination (MMSE) test by Folstein. Descriptive statistics, t-test, Mann-Whitney-U, Kruskal-Wallis-H test and One-Way-Anova with post hoc Bonferroni were used in order to determine gender, age and cognitive score effects on strength. Significance was set at p<0.05. All elderly people were compared according to age and MMSE groups.
AGE-RELATED DIFFERENCES IN VO2MAX ESTIMATE AND COGNITIVE PERFORMANCES IN ATHLETES AND ACTIVE NON-ATHLETES BETWEEN 49 AND 73 YEARS OLD

Bherer, L., Bosquet, L., Renaud, M., Labelle, V.
Institut universitaire de gériatris de Montréal, Université du Québec à Montréal, Université de Montréal, Canada

An increasing number of studies suggest that physical activities might protect against age-related cognitive decline. In fact, aerobic training leads to a significant improvement in VO2max that correlates with increased cognitive performances in sedentary older adults (Kramer et al. 1999), with larger benefits in attentional control functions, required to share attention between multiple tasks. The effect of physical fitness on brain structures and functions in humans remains to be elucidated, but proposed hypotheses suggest an increased vascularization of brain tissue. However, most studies published so far include moderately active healthy individuals and no study has assessed whether the positive impact of cardiorespiratory fitness on cognition holds for athletes or highly active individuals who engage in intense fitness training programs.

In this study, we assessed fitness condition and cognitive performances in athletes and moderately active non-athlete individuals of two age strata, to further explore if fitness training has a protective effect against age-related declines in highly active and trained individuals. Twenty-three adults aged between 49-59 years old (mean age of 54.5) and 20 adults aged 60-73 (mean age of 65) completed the Rockport 1-mile test (VO2max estimate) and clinical neuropsychological tests of attention and psychomotor speed. They also completed a computerized dual-task paradigm to assess attentional control, required to divide attention between two concurrent tasks. A median-split on VO2max estimation allowed forming high and low fit groups in each age strata. The results indicated a significant age by fitness level interaction (F=5.6, p<0.05), due to a significantly larger loss (p<.001) in fitness level after 60 years old in the high fit group (VO2max estimate in ml/min/kg was 54 for younger and 52 for older high-fit individuals) compared to the age-related difference observed (p=0.001) in the low-fit group (VO2max estimate was 37 and 32 for younger and older respectively). The results also showed a significant age-related difference in dual-task performances (p<0.001), with no age-difference in the single task condition, in the high fit group only. This suggests a specific cognitive decrease in the condition tapping attentional control functions. A significant decline with age in attentional control functions and fitness condition in the high fit group supports the relationship between fitness and cognition in older adults reported in previous studies. However, results of this study also suggest that very high fit individuals are more likely to experience a reduction in fitness level from the fifth to the seventh decade accompanied with reduced performances in cognitive tasks requiring attentional control.

walk (p<0.001). 7.3% of the 1,897 patients without a walking aid had experienced a fall, whereas 16.4% of the 214 patients who were not able to walk without an aid had experienced a fall. Conclusion The incidence of self-reported falls and the prevalence of impairment measured by the inability to walk without an aid are high in elderly people. As expected, the ability to walk independently was associated to the level of physical activity. Furthermore, the frequency of falls seems to be reduced when the person is able to walk without an aid. There seems to be no relevant association between the fall status and the activity level. Considering the relevance of regular physical activity for health, the preservation of walking ability should be a major aim in elderly health care.

The study has been conducted within the research cooperation PRISCUS (Prerequisites for a new health care model for elderly people with multimorbidity) which is funded by the German Federal Ministry of Educa

LEISURE-TIME PHYSICAL ACTIVITY REDUCES SELF-REPORTED GASTROINTESTINAL PROBLEMS OF SHIFT-WORKERS

Morris, C., Fullick, S., Grindley, C., Waterhouse, J., Atkinson, G.
Liverpool John Moores University, United Kingdom

A large proportion of shift-workers suffer some type of gastrointestinal (GI) discomfort that impairs their quality of life [Atkinson et al., 2008]. Leisure-time physical activity (LTPA) has been demonstrated to decrease GI problems reported by people living a diurnal lifestyle (Brown et al., 2000). A LTPA mediated change in dietary habits is a possible explanation for this observation, but such a change might not be feasible for shift-workers, whose dietary habits are already disrupted by their work schedules. Thus, we examined whether LTPA reduces shift-worker’s GI discomfort by altering their dietary habits.

Male (n=111) and female (n=50) shift-workers, with mean (SD) age of 39 (9) y, body mass of 83 (14) kg, height of 1.75 (0.1) m and body mass index of 27 (4) kg m-2, completed the Standard Shift-work Index, together with a food frequency and LTPA questionnaire. Participants were allocated to low, moderate and high LTPA tertiles and the incidence of self-reported GI problems was compared between groups using 1-way ANOVA. Differences in LTPA between shifts (morning, evening and night) were examined using linear mixed modelling. Data were logarithmically transformed prior to analysis to control for skewed distributions, and are presented as geometric mean and 95% confidence intervals (CI).

Gastrointestinal discomfort was significantly (P=0.02) more prevalent in the low LTPA group (16 units, CI = 15 to 16 units) compared to the high LTPA cohort (13 units, CI = 12 to 15 units). There was no significant (P=0.05) difference between the moderate LTPA group and the two other groups in prevalence of GI discomfort. Average daily energy intake from fat, carbohydrate (CHO), protein and total energy consumption did not differ between the LTPA groups (P>0.05). Energy intake from fat (2.9 MJ, CI = 5.6 to 6.2 MJ), CHO (5.6 MJ, CI = 8.1 to 22 MJ), protein (2.4 MJ, CI = 5.2 to 5.6 MJ) and overall energy consumption (10.4 MJ, CI = 12.4 to 14.38 MJ) were significantly higher on rest days compared to days working morning, afternoon and night shifts (P<0.001). There were no interactive effects of shift and amount of LTPA on the average daily energy intake from these sources (P>0.05).

These data suggest that LTPA can reduce the occurrence of self-reported GI problems in shift-workers. However, this effect does not appear to be mediated through altered dietary content. Thus, biological or other behavioral factors (e.g. the timing of eating habits) may be involved in the positive effect of LTPA on perceived GI problems. In conclusion, shift-workers should expend 8805.9.6 MJ per week during LTPA in order to decrease the prevalence of subjective GI problems and improve their quality of life.

MOTOR COMPETENCE IN CHILDREN WITH MILD MENTAL RETARDATION AND CONTROLS

Vandendriessche, J., Vandorpe, B., X, Vaeysens, R., Matthis, S., Lenoir, M., Philippaerts, R.
Ghent University, Belgium

Motor and cognitive development are believed to occur in close interaction with each other, although the literature on this issue is somewhat equivocal. The aim of this study was to compare motor competence of children with mental retardation with a reference sample of normal children in Flanders. Therefore, anthropometrical and physical measurements as well as motor skill evaluation by means of standardized motor skill test batteries were performed in subjects attending schools for children with mental retardation (N = 138) and subjects attending regular schools (N = 2538; boys and girls, 6-11 years of age). These tests included grip strength, explosive power, trunk and shoulder flexibility, strength of trunk muscles, endurance and arm strength. Additionally, the BOT2-SFI and KTK2 test batteries were performed.

Mild mentally retarded children tended to be smaller and heavier, which accumulated in a significantly higher BMI (17.5 +/- 3.7 versus 16.9 +/- 2.6 for the control group). When compared to the control group, children from special schools showed lower muscle strength (grip force), explosive power (counter movement jump), less flexibility in hips and shoulders, lower sprint speed and endurance. In addition, they scored worse in every single item of the BOT2-SFI and their KTK scores were significantly lower than those of the controls. These findings indicate that the lower general motor competence of children with mental retardation seems to result from a lower physiological competence (e.g. strength, endurance) as well as from a lower motor skill level, i.e., problems in coordinating and controlling movements.

MODULATIONS OF LEG AND JOINT STIFFNESS DURING DROP JUMPING BY OBSERVING THE JUMP MOVEMENTS OF A MODEL AND THE LEARNERS

Koike, T., Inukai, T., Yamada, T.
Hokkaido University, Japan

The utilization of impact shock and motor skills that allow the shortening of contact time are required for better performance in drop jumping (DJ). The parameter to identify the acquisition of skills is leg and joint stiffness. A study showed that leg stiffness during DJ is influenced by the provision of verbal instruction about foot contact duration (11), thus, indicating that stiffness is a self-controlled motor skill. Meanwhile, the conventional method of improving the motor skills depends on the somatosensory information during a motor task. However, in an arm-reaching task with manipulandum, an improvement is noticed in the learner’s skills by observing a movie of a model performing the same task (2). On the sports field, since the demonstrated motor skills the learner observed are generally acquired skills, the learner cannot observe the process of the demonstrator’s skill improvement. However, an observation of the movies of both the model’s and the learner’s own movements may help the learner to notice the differences between the two movements; the observation plays an important role in improving the learner’s skills. Moreover, the procedure may change the learner’s stiffness during DJ. We aimed to test the hypothesis.

We selected one student as a model and 24 students with no experience in DJ as subjects for an action observation. The model performed six DJ trials. The subjects performed four trials before the observation (pretest). For both the model and the subjects, the observations were recorded (30 fps) for the last trial and for analysis in the other trials. The subjects were divided into three groups (GP) according to the observation type GP1: observation of both the model’s and their own DJ, GP2: observation of only the model’s DJ, GP3: no observation. During the observation, the subjects observed the video projected on a face-mounted display. After the observation, the subjects performed three more DJ trials (posttest). Kinematics (240 fps) and ground reaction force (2000 Hz) were recorded during each trial. Leg stiffness and ankle and knee joint stiffness were calculated using the collected data; the data pre- and post-tests were compared. During the pretest, leg stiffness was observed to be greater for the model than for the subjects (727.72 vs. 157.41 N/m/kg); therefore, the model’s DJ skill was considered to be ideal. Only GP1 showed significant changes in leg and knee joint stiffness between the pre- and post-tests (1.19 vs. 2.65 N/m/degree; 101.64 vs 222.87 N/m/kg).

The fact that the stiffness increased only in GP1 indicates that observing both the model’s and learner’s movements is an effective method to enhance motor skills when the learner understands the task that requires to use external force. The difference in DJ motion found during the observation may contribute to rectifying motor commands for stiffness modulation.

CYCLING IMPAIRS NEUROMUSCULAR COORDINATION DURING RUNNING IN TRIATHLETES: THIS IMPAIRMENT REDUCES PERFORMANCE, IS ASSOCIATED WITH INCREASED RISK OF INJURY BUT CAN BE IMPROVED BY A TAPING INTERVENTION

Chapman, A., Vicenzino, B., Hodges, P., Dowlan, S., Hahn, A.
Australian Institute of Sport, Australia

Triathletes report incoordination when running after cycling. Fatigue is likely to contribute to this perceived incoordination but impaired coordination of running may also be due to interference with neuromuscular control independent of fatigue. Interference with neuromuscular control may result from repeated prior performance of the movement pattern of cycling. However, the direct effects of cycling on neuromuscular control of running are unknown, as are the implications of any interference with neuromuscular control for performance and injury, and b) our ability to address any interference. PURPOSE To investigate a) the influence of the bike-run transition on neuromuscular coordination of running (i.e. does cycling have a direct effect on running?); b) the effect of altered neuromuscular coordination on run economy (ER, steady-state VO2); c) the association between a history of exercise-related leg pain (ERLP) and neuromuscular coordination of running; d) the role of fatigue in coordination changes, and e) the effectiveness of taping as an intervention for impaired neuromuscular coordination of running. METHOD 27 highly-trained triathletes participated. D Kinematics and muscle recruitment of the lower limb were compared between a control-run (no prior exercise) and a 30 min transition-run (preceded by 20 min of cycling, i.e. run vs. cycle-run). RE was measured using established procedures. Fatigue indicators from EMG and force data were evaluated using an established isometric fatigue protocol. Neuromuscular coordination was compared between transition runs with and without augmented low-Dye anti-pronation taping applied to both feet. RESULTS Kinematics were not different between control- and transition-runs. Muscle recruitment was different in 5 of 17 triathletes without injury history (65.6 ± 11.4% change in mean EMG amplitude); altered muscle recruitment during the transition-run was more similar to recruitment used during cycling (39.2 ± 5.86% increase in corollation for similarity of running and cycling muscle recruitment). Altered muscle recruitment was associated with a 3.7 ± 0.9% increase in VO2. Muscle recruitment was altered in 7 of 10 triathletes with a history of ERLP. Altered muscle recruitment was not associated with indicators of fatigue from myoelectric and force data, but was less when taping was used (70.5 ± 18.6% reversal of altered muscle recruitment). CONCLUSION Short periods of cycling have no direct effect on running kinematics or muscle activity in most (~70%) highly-trained triathletes. However, running muscle activity is influenced by cycling in a proportion (~30%) of highly-trained triathletes. This influence is not related to altered kinematics or fatigue, but instead is a direct effect of cycling on motor commands for running. This altered muscle recruitment is associated with reduced RE and 2.5 times greater likelihood of a history of ERLP, but can be improved by the use of an established taping technique.

BILATERAL TRANSFER OF LEARNING DEPENDS ON INHERENT TASK DEMANDS

Stöckel, T., Krug, J.
University of Leipzig, Germany

Introduction

Transfer of learning describes the influence of a previously practiced or performed skill on the acquisition of a new skill or the same skill in a new context. If transfer of learning occurs be-tween two limbs, it is called bilateral transfer of learning (Magill, 2001). The most important question for coaches and athletes about the bilateral transfer effect concerns its direction. There is little evidence, that bilateral transfer is asymmetric, what means that one limb bene-fits more from practice of the other limb. But it is controversy discussed, whether bilateral...
transfer occurs in higher amounts from preferred to non-preferred limb, or vice versa. In our study we expected, that the direction of bilateral transfer of learning depends on inherent task demands. Therefore, two experiments have been carried out, which required school children to learn a complex motor skill with (1) high demand on spatial accuracy or (2) high demand on force production and control.

Method
A total of 66 subjects were involved in two experiments to the acquisition of (1) a slalom-dribbling task in basketball (n = 30) and (2) a throwing task in handball (n = 36). In a counterbalanced crossed transfer paradigm participants practiced one of the tasks over four weeks in one of two training regimes: (P-NP) Subjects initially practiced four sessions only with their preferred limb and changed to the non-preferred side for another four session, (NP-P) Subjects initially practiced four sessions only with their non-preferred limb and changed for another four session to the preferred side. All subject were tested before practice, after the first four sessions, at the end of the training sessions and after one week without practice on both limbs separately. Bilateral transfer was assessed directly through the improvement on the nonpracticed limb (1st test repetition) and indirectly through the influence of the practiced limb on the learning of the skill on the second limb (2nd test repetition). The persistence of the bilateral transfer of learning was examined in the 3rd test repetition.

Results and Discussion
Bilateral transfer of learning occurred in both experiments, but differently in its direction (asymmetric transfer) and manner. While in the acquisition of the dribbling-task direct transfer and indirect influences on the nonpracticed limb only appeared from non-preferred to pre-furred, for the acquisition of the throwing-task only indirect influences from preferred to non-preferred limb could be shown. These results are in line with previous findings on simple motor tasks and support the suggestion, that bilateral transfer of learning is task-specific. As a practical implication these findings indicate, that in early stages of motor learning tasks de-manding high spatial accuracy should be taught differently from tasks with high demand on force control and production.

FREELY CHOSEN PEDAL RATE IS UNAFFECTED BY SEPARATE INCREASES IN CARDIOPULMONARY AND MECHANICAL LOADS THAT CONTRIBUTES TO THE DESIGNATION AS A ROBUST INNATE VOLUNTARY MOTOR RHYTHM

Hansen, E.
Norwegian School of Sport Sciences, Norway

INTRODUCTION
Freely chosen pedalling during submaximal cycling represents a voluntary rhythmic movement. Suggestively, such a rhythmic movement could be largely influenced by central pattern generators that are rhythmically active neural networks located in the spinal cord (Zehr 2005). While it is assumed that the output from the central pattern generators is affected by e.g. sensory feedback, it is unknown to what extent the freely chosen pedal rate is affected by cardiopulmonary and mechanical loads. This was, therefore, investigated.

METHODS
Recreationally active individuals (4 males and 4 females, 32±5 years, 175±8 cm, 74±15 kg) who were accustomed to cycling, without being competitive cyclists, participated. On an electromagnetically braked cycle ergometer, placed in a hypobaric chamber, each participant's freely chosen pedal rate was found during three different 10-min cycling bouts: (i) work rate corresponding to 65% of maximal oxygen uptake (VO2max), at 200 m altitude (laboratory location); (ii) work rate as in (i) but at 3,000 m simulated altitude resulting in ~80% of VO2max, and, (iii) work rate corresponding to ~80% of VO2max, at 200 m altitude. A 7% reduction of VO2max and 2 beats/min reduction of maximal heart rate per 1,000 m increase of simulated altitude was assumed (Wehrlin, Hallén 2006) for estimations of relative values of oxygen uptake and heart rate. Condition (i) and (ii) allowed comparison of freely chosen pedal rate under constant mechanical load on the legs while varied cardiopulmonary load. Condition (iii) and (iii) allowed comparison of freely chosen pedal rate under constant cardiopulmonary load while varied mechanical load.

RESULTS
Relative oxygen uptake was 65±3%, 82±5%, and 82±4% of VO2max for condition I, II, and III, respectively. Heart rate was 78±4%, 89±5%, and 91±3% of the maximal heart rate, respectively. For these physiological responses, taken to reflect cardiopulmonary load, differences occurred between condition I and II while not between II and III. Work rate, reflecting mechanical load, was 173±32, 173±32, and 224±37 W in condition I, II, and III, respectively (p<0.05 for condition II vs. III). Freely chosen pedal rate was 86±13, 88±11, and 85±11 rpm for condition I, II, and III, respectively (p>0.05).

DISCUSSION AND CONCLUSION
Freely chosen pedal rate was unaffected by increased cardiopulmonary load at a constant mechanical load - and vice versa. From this, and other results showing the freely chosen pedal rate to be steady and at the same time largely individual over 3 months (Hansen 2008), the freely chosen pedal rate is suggested to be a robust innate voluntary motor rhythm, likely under primary influence of central pattern generators that again are minimally affected by cardiopulmonary and mechanical load.

BRAIN ACTIVITY: HOW EXPERTS DIFFER FROM NOVICES IN GOAL-DIRECTED SPORTS PERFORMANCE

Baumeister, J., Reinecke, K., Herbarth, B., Liesen, H., Weiß, M.
University of Paderborn, Germany

Purpose: Skilled performance in a goal-directed motor task is dependent on the ability to process internal and external information in an effective manner and decide which pieces of information are important and which are irrelevant. On a cortical level focused attention and somatosensory information processing in the concept of working memory play a crucial role in this process. The electroencephalography (EEG) is able to monitor these changes in frontal and parietal brain areas (Theta and Alpha-2 spectral power) during cognitive and sensorimotor tasks. Less is known about these parameters in a complex goal-directed sports performance. Therefore EEG recordings were examined during a goal-directed golf putting to examine electro-cortical changes related to information processing and focused attention in an expert-novice paradigm.

Methods: Nine male, right-handed experienced golfers (26.4±4.1 years, 86.7±4.8 kg, 189.4±21 cm, 7±6 ± 4.2 years golf experience, playing golf 3.0±7.0 hours/week) with golf handicap of 8.3±7.5 were compared to nine male, right-handed novice volunteers (24.6±3.4 years, 82.6±31 kg, 184.3±7.1 cm, no golf experience). Participants were required to putt balls as accurate as possible at their own
pace during a 5 x 4 min putting series. During the performances the EEG was measured in accordance with standards of the international 10:20 system from 13 scalp locations (Fz, F3, F4, Cz, C3, C4, P3, P4, T3, T4, T5, T6) and divided into different frequencies: Theta (4.75-7.5 Hz), Alpha-1 (7.9-9.5 Hz), Alpha-2 (9.75-12.5 Hz) and Beta-1 (12.75-18.5 Hz). Performance-related power values were calculated and log-transformed.

Results: Statistical analysis showed significantly better performance in the expert golfers (F1,16=114.328, p<.001; part r2=.864). This was associated with higher frontal Theta power (F1,16=5.275, p=.05; df=248) and increased parietal Alpha-2 power values (F1,16=8.482, p=.01; part r2=.346) compared to the novices in golf putting.

Conclusion: In summary, the results of this study demonstrate that performance-related power values measured by EEG were associated with skill level in a goal-directed golf putting series. The findings suggest that with increasing skill level, expert golfers have developed task solving strategies which came along with focused attention (increased frontal Theta power) and an economy in neural activity during sensory information processing in the somatosensory cortex (increased parietal Alpha-2 power). With the theoretical framework of the working memory it seemed to develop a model for goal directed sports performance like golf.

SHORT-TERM CHANGES IN MUSCLE ACTIVITY TO AN ELASTIC CORD TECHNIQUE TRAINING DEVICE DURING TREADMILL RUNNING

Haudum, A., Birkbauer, J., Kröll, J., Müller, E.
Christian Doppler Laboratory Biomechanics in Skiing*, University of Salzburg, Austria

Modern motor learning theories, such as differential learning approach (Schöllhorn 2006) and the coordination dynamics theory (Kelso 2006), consider noise or movement variability as an essential, inherent factor for technique stabilization and improved learning. According to Bernstein (1967) movement results from forces generated directly by muscle contraction and reactive phenomena (gravitation, inertia, forces stored in muscle-tendon unit). Neuromuscular impulses must adjust to produce constant movement outcome due to changing forces of non-muscular genesis. In order to achieve the ability to adapt to such changes, reactive phenomena should be increased in the training process but not exceed the solution space. The aim of our study was to compare short-term changes in variability of muscle activity during treadmill running when using a technique training device and controlled running.

Six males ran 2 x 30 min intervals at 2.9 m/s separated by a 30 min rest period. After the first 5 min of either the first or the second 30 min-interval, elastic cords were attached at iliosacral joint and both heels. The cords act to increase the degrees of freedom. They then ran for 20 min followed by 5 min free running. The cord length was standardized at 40% of the leg length (producing ~48 N at 100% leg length). Muscle activity of the rectus femoris (RF), tibialis anterior (TA), lateral gastrocnemius (LG) and stride duration (ST) were measured. IEMG for each stride was measured. Standard deviations (SD) between strides in 2-min-blocks were calculated to assess movement variability.

Average IEMG increased between 21.1 and 68.0% for the three muscles after the switch from free to cord running, whereas ST changed by 1.4%. A 2 X 2 ANOVA revealed a strong interaction between cords and free running by p2 between .63 and .70 (p<.06) for IEMG. Readaptation from cord to free running showed a prolonged muscle activity and variability only for TA illustrated by an increase of 11.1% and 14.5% to the first 5 min free running (p<.001). The increase in average IEMG and stride-to-stride variability is potentially a result of increased forces generated by cords or the inability to profit from occurring forces for generating the movement pattern as described by Bernstein potentially assigned to their first time experience. The basic idea to induce higher movement variability within solution space by applying cords is confirmed by the higher EMG variability compared to ST.

THE EFFECT OF DEHYDRATION ON COGNITIVE PERFORMANCE IN ELITE FEMALE FIELD HOCKEY PLAYERS FOLLOWING INTERMITTENT EXERCISE IN THE HEAT

MacLeod, H., Sunderland, C.
Nottingham Trent University, United Kingdom

Background: Little is known about the combined effects of dehydration and heat stress on cognitive performance in elite female athletes. In the case of team sports, it is crucial players execute a high degree of mental functioning for skill execution, reading play and processing tactical changes. Baker and colleagues (2007) showed that fluid ingestion during exercise was essential in maintaining vigilance-related attention in male basketball players. The aim of this study was to investigate the combined effect of fluid ingestion and field hockey specific exercise in the heat on cognitive performance in elite female players.

Methods: Seven elite female field hockey players (mean ± SD, 22 ± 4 yrs; body mass 61.9 ± 5.4 kg, height 166.6 ± 5.1 cm; VO2 max 52.9 ± 2.9 ml/kg/min) performed 30 min of a field hockey-specific intermittent treadmill protocol (FHITP) in the heat (33oC, 60% RH) on two occasions, separated by at least 7 days. The FHITP was individualised based on work rate and consisted of different exercise intensities observed in match play (total distance = 6967 ± 266 m). On one occasion subjects were restricted from consuming any fluid (NF); in the other it was ad libitum (FL). An exercise intensity corresponding to ~92% HRmax was subjectively assessed using rate of perceived exertion (RPE) and perceived thirst were measured at regular intervals during exercise.

Results: Body mass loss was significantly greater (P<0.001) in the NF trial, equating to mean percentage body mass losses of 0.5 ± 0.5% and 2.5 ± 0.5% for the F and NF trials, respectively. HR and Trec were similar between trials, however, RPE and perceived thirst were significantly higher in the NF trial (P<0.001). Fluid ingestion significantly improved (P=0.023) reaction time for the executive function and log-transformed.
Conclusion. Volume = 3.3% ± 5.2% vs 5.1% ± 7.9% in B+W and W, respectively, all p < 0.001) and thirst score decreased at pre-exercise levels. Plasma volume increased significantly after the rehydration period in both trials (fat free mass = 0.09% ± 1.5% vs 1.3% ± 1.2%; plasma.

NEUTROPHIL DEGRANULATION RESPONSE TO CARBOHYDRATE AND PROTEIN FEEDING AFTER PROLONGED EXERCISE

Costa, R., Blanchfield, A., Oliver, S., Laing, S., Walters, R., Bilzon, J., Walsh, N.
Bangor University, United Kingdom

Objective: To determine the effects of immediate and delayed carbohydrate (CHO) and protein (PRO) feeding on neutrophil degranulation responses after prolonged exercise.

Methods: Nine trained male runners completed three feeding interventions in randomised order after 2 h running at 75% VO2max. On the control trial (CON) participants received water immediately post-exercise and 1 h post-exercise. On the immediate feeding trial (IF) participants received a CHO-PRO solution equal to 1.2 g CHO/kg/BM and 0.4 g PRO/kg/BM immediately post-exercise and water 1 h post-exercise. On the delayed feeding trial (DF) participants received water immediately post-exercise and CHO-PRO solution 1 h post-exercise. All fluid boluses were prepared with water equal to 12 ml/kg/BM. Venous blood samples were collected pre-exercise, post-exercise, and at 20 min intervals until 140 min post-exercise. Neutrophil counts were determined using an automated cell counter. Elastase release from bacterial-stimulated neutrophils (degranulation) was determined using ELISA. Data were analysed using a trial x time repeated measures ANOVA with post hoc Tukey's HSD.

Results. The post-exercise circulating neutrophilia was similar throughout the recovery period measured (main effect of time: P< 0.001) on CON (8.2 ± 0.9 x10 9/L), IF (8.8 ± 1.1 x10 9/L) and DF (8.4 ± 0.8 x10 9/L). Neutrophil degranulation (% change in elastase release per neutrophil significantly decreased during recovery on CON and DF (24% and 31% at 140 min vs. pre-exercise, respectively; P< 0.01), but remained unchanged on IF. Neutrophil degranulation was significantly lower on CON at 100 and 140 min post-exercise (P< 0.05) and DF at 80 min to 140 min post-exercise (P< 0.01) compared with IF. Conclusion: These results indicate that consuming a CHO-PRO solution equal to 1.2g CHO/kg/BM and 0.4g PRO/kg/BM immediately after, but not 1 h after, prolonged strenuous exercise prevents the decrease in neutrophil degranulation.

REHYDRATION AFTER EXERCISE UNDER HOT ENVIRONMENT: EFFECTS OF BEER VS WATER

Facultad de Ciencias de la Actividad Física y del Deporte. Universidad Politécnica de Madrid, Spain

Introduction. Beer is characterized for its low alcoholic content and notable amount of low molecular weight maltodextrins, amino-acids, minerals, B group vitamins, anti-oxidants, and carbohydrates. Hence, moderate intake of beer could be an alternative in the restoration of fluid balance after exercise-induced dehydration.

Aim. To determine the effectiveness of beer intake (660 ml) in restoring fluid balance after exercise-induced dehydration compared with the effect of water intake.

Material and methods. In a cross-over study design, sixteen healthy male volunteers (age: 21.1 ± 1.4 years, VO2max: 55.9 ± 3.6 ml.min.kg⁻¹) performed two randomized trials separated by a 3 weeks interval. In each trial the subjects exercised at 60% of maximum aerobic speed in hot environment during 60 minutes (35 ± 1 ºC, 60 ± 1 % relative humidity). After the exercise bouts, the subjects rest for 2 h in a separate chamber at the same environmental conditions and were asked to drink 660 ml of beer plus water ad libitum (trial B+W), whereas in the other trial the participants were allowed to drink only water (trial W). The subjects were weighted before exercise, after exercise and after 2 h of rehydration. Additional measured variables included fat free mass (measured by dual-energy x-ray absorptiometry), percentage of change in plasma volume and thirst scale. Urine volume and fluid intake were collected during the rehydration period.

Results. A decrease of 2.4 ± 0.3% of their body weight was observed. A decrease in fat free mass and plasma volume occurred after exercise in the heat (all p < 0.001), whereas thirst score increased significantly after exercise in both trials (all p < 0.001). During the rehydration period, there were no differences in the amount of fluid intake between trials (6260 ± 587 vs 1644 ± 620 ml in B+W and W, respectively, p = 0.91). The urine volume was also similar in both trials (281 ± 374 vs 223 ±245 ml, in B+W and W, respectively, p = 0.70). After two hours of rehydration, the subjects recovered 1.3% and 1.6% of body weight in the B+W and W trials, respectively (p = 0.29). Fat free mass and plasma volume increased significantly after the rehydration period in both trials (fat free mass = 0.09% ± 1.5% vs 1.3% ± 1.2%, plasma volume = 3.3% ± 5.2% vs 5.1% ± 7.9% in B+W and W, respectively, all p < 0.001) and thirst score decreased at pre-exercise levels.

Conclusion. The results of the present study suggest that beer could be an alternative effective post-exercise rehydration drink in healthy moderately trained young adults, even under hot environment. Thirst was not enough for stimulating voluntary drinking and recovering full body weight loss. In addition, it is important to highlight that the messages related to the benefits of moderate consumption of alcohol have always been addressed to adult populations.

ENERGY INTAKES AND BODY COMPOSITION IN COMPETITION ATHLETES

Silva, M.
University-Fernando Pessoa, Portugal

Female athletes participating in sports that require gracefulness and technique, like gymnastics, ballet, diving are under a great pressure of keeping a lean body. The very short gymnasts' career embraces very young athletes, who are undergoing the very important processes of growth and development for their future life. Although gymnasts seem to be at a low level of energy intake, few investigations have examined this concern, especially in female athletes.

The primary aim of this investigation was to study and to compare energy intake and body composition in seventy competition female gymnasts (12.3 (2.6) (years); 142.3 (11.1) (cm); 36.7 (8.4) Kg) of Federação de Ginástica de Portugal (Portuguese Gymnastic Federation) in preparatory and transitory period to 9,6 (2,5)% in the end of season.

Energy intake in most sports was lower than recommended for moderately exercising athletes, as average practice time was 96.4 +- 58.2 minutes per day. Independent of exercise-related aspects, risk groups for low nutrient intakes were identifiable among the junior athletes. For example, iron intake was strongly correlated with energy intake (r-squared = 0.74, p < 0.001). Consequently, relative iron intake was significantly lower in female athletes (93 +- 32 % RDA vs. 145 +- 51 % RDA (males), p < 0.001).

RESULTS & DISCUSSION: Within the monitoring period, the average activity level (EE/resting EE) of the monitored athletes was 1.71 +- 0.22. Consequently, carbohydrate intake in most sports was lower than recommended for moderately exercising athletes, as average practice time was 96.4 +- 58.2 minutes per day.

The present report includes data from 72 male and 85 female athletes (16.7 +- 3.3 y, 65.7 +- 13.5 kg, 174. 7 +- 10.7 cm) from 17 different sports, who visited the Centre between January and December 2007.

VALIDATION OF THE COLOGNE NUTRITION AND ACTIVITY PROTOCOL USING DOUBLY-LABELLED WATER, INDIRECT CALORIMETRY AND 24H UREA EXCRETION

Koehler, K., Braun, H., De Marees, M., Fusch, G., Fusch, C., Mester, J., Schauenzer, W.
German Research Centre of Elite Sports, Cologne, Germany

INTRODUCTION: Assessment of the nutrition status of elite athletes depends on valid methods for determination of both nutrient intake as well as physical activity. Prospective methods such as dietary protocols seem well suited for routine assessment of nutrient intake. Physical activity can be assessed with activity protocols (API), thus enabling the simultaneous approximation of energy expenditure (EE).

Validation of energy intake (EI) and physical activity can be obtained by using doubly labelled water (DLW) as an independent biomarker, which is considered to be the gold standard in field situations. During exercise in laboratory conditions, indirect calorimetry (IC) can be used to determine EE. As an additional tool, 24h urea excretion has been established as a marker of protein intake. The aim of the present study was to validate the Cologne nutrition and activity protocol by using DLW, IC and 24h urea excretion as reference methods. The highly standardized nutrition protocol consists of predefined food items and portion sizes. Nutrient intake is calculated with EBIS nutrition software (version 7.0). The activity protocol contains predefined activities, with strong emphasis on sport-related activities. EE is calculated from AP data on the basis of reference data.
The primary goal of games teaching is enhancing pupil’s game playing ability. Small-sided games are considered to provide more learning opportunities compared to the full game (Capel, 2000). This study was conducted to examine if there is a differential amount of learning opportunities in basketball 3 on 3 versus 5 on 5 game play situations. Additionally, players’ heart rates in both conditions were measured with IC in all subjects (mean r-squared: 0.86 +- 0.07 (running), 0.94 +- 0.02 (cycling)). Dietary protein intake was significantly correlated with 24h urea excretion (r-squared = 0.51, p < 0.001). These preliminary data indicate that the Cologne nutrition and activity protocol is a valid tool for assessing the nutrition status in athletes.

THE SELF-EFFICACY OF PRE-SERVICE PHYSICAL EDUCATION TEACHERS' AND IT SOURCES

Onofre, M., Jardim, M.
Human Kinetics Faculty, Technical University of Lisbon, Portugal

Introduction
Teachers’ self-efficacy has been detached as having a determinant influence on teaching quality (Onofre; 2000; Henson, 2002, Woolfolk Hoy & Spero, 2005), namely because it affects the quality of teachers pedagogical knowledge (Onofre, 2000), and teachers’ commitment, effort and motivation to teaching (Bandura, 1997). Some studies underline that teachers’ self-efficacy can be reinforced through different kinds of experiences (sources of self-efficacy) (Tschannen-Morgan, Hoy & Hoy, 1998), mainly during the teacher first year of teaching (Woolfolk Hoy & Spero, 2005). Research have indicated that verbal persuasion (Hoy & Tschannen-Moran, 2006) and mastery experiences (Tschannen-Morgan, Hoy & Hoy, 1998) are the main teaching self-efficacy sources for pre-services teachers. This study aimed to analyse the variation of the self-efficacy beliefs of the pre-service physical education teachers during their practicum, and to identify the its sources.

Methodology
This study was carried out in two phases. During the extensive phase, two questionnaires were applied to 88 PE pre-service teachers, to estimate the variation of their personal teacher efficacy and specific classroom teaching self-efficacy (Onofre, 2000). A comparative statistical analysis was used. An intensive phase consisted of a multi-case study. Eight pre-service teachers representing two clusters of the teacher self-efficacy variation (under percentile 25 and upper percentile 75) were interviewed to identify the sources of their teaching self-efficacy. Their answers were submitted to an inductive content analysis.

Results
Results had shown a moderate but significant correlation between general and specific teachers self-efficacy. The specific self-efficacy beliefs of pre-service teachers had a significant increment in classroom instruction, management and climate. No significant changes were found in classroom discipline. The sources of self-efficacy that teachers argued as most influential were the verbal persuasion and the mastery experience.

TEACHERS' PERCEPTIONS OF GENDER RELATIONS IN SCHOOLYARDS

Diketmüller, R.
University of Vienna, Austria

Introduction
Children and youth do gender differently according to which place they are at (Arnesen & Laegren 2004). Also schools and school yards are places where activities are very stereotype and traditional gender roles are re-/produced (Boyle 2003; Pellegrini 1995, Shilling 1991, Thorne 1993). Diketmüller & Studer (2007) examined physical activities concerning gender play in school yards and identified different factors which influence the gender play at school recess. In the following paper the focus of the study lies on teachers’ and educators’ perceptions of gender relations in school yards and physical activity and their influence in the process of gendering institutions.

Methods
To examine the influence of the teachers and their attitudes on physical activities concerning gender play in school yards, the data of participant observation in 20 Austrian school yards (60 recesses) were applied and compared with the data of structured interviews with directors (n=20) and teachers (n=29). The data were analysed by content analysis technique.

Results
The findings of the interview data lead to the assumption that teachers have diverse estimations about how boys and girls use the school yards and playground via physical activities. Teachers assume both gender stereotyped activities and no differences between girls and boys. Those teachers, whose ratings differ conspicuously from the observed activities of girls and boys in the school yards, had also more traditional explanation approaches on gender and gender differences in physical activities. The results also showed that the gender awareness of the teachers contributes girls’ and boys’ activities in school yards: if and how disadvantages by gender are seen, how gender issues are dealt with, how activities of boys and girls are appraised and supported or how usages are negotiated and which rules are rearranged.

Discussion
This study shows the need of a higher gender awareness of teachers because the uncritical current use of school yards often still contribute to the production of (unequally) gender relations. That teachers are sensitised to their contribution to the process of gender-reproduction in school seems to be a condition precedent for changing gender relations. Based on the study, different approaches are discussed, how to enable less gender-stereotyped activities at school.

A SOCIO-CULTURAL PERSPECTIVE ON HUNGARIAN STUDENT TEACHERS’ EXPERIENCE WITH PLAY
Kovács, K., Szilárd, Z.
Semmelweis University Faculty of Physical Education and Sport Science, Hungary

The soul of the child needs to have play” articulated Plato on the role of childhood games in Laws (793. B.C.E.). Fröbel added ‘A child’s play is his work, the highest expression of human development in childhood.’ Teachers and psychologists agree that the intellectual and physical stimulation of both spontaneous and organized games are required for the personality development of children. According to some, (Lancy, 1976; Schwartzman, 1983; Rigler, 2004) traditional games are significantly influenced by social and socio-cultural circumstances.

In Hungary the theoretical and practical teaching of games in teacher education draws on significant traditions. Despite this, students’ experience and knowledge of games is relatively poor in higher education, and when learning games a significant portion of students tend to be reluctant and passive rather than active participants.

For this reason we attempted to map the knowledge of games among 1st year students studying to educate children in the future with the following questions:

- Does the population size of a community influence playing habits?
- Is play more frequent in families with several children?
- Do regular sports activities influence the willingness to play?

In addition to registering demographic data, the questionnaire consisted of 25 close-ended and 4 open-ended questions.

Students completed the questionnaire at the first session of the school games course in the autumn semester of the 2007/2008 academic year (N=224).

In our study we inquired about both intellectual and physical games. Contrary to our expectations, neither settlement population size nor the number of siblings influenced the frequency of play in either case. The number of siblings did not statistically influence play habits; however it is important to mention that almost all the students coming from big families (3 or more children) said that they had played games within the last month.

Most surprising was that the number of years spent actively participating in sports also did not have a significant influence on the students’ willingness or motivation to play or the amount of spare time spent playing games. There were no significant differences between girls and boys in the study.

The results of the students’ group reveal that enjoyment, the improvement of physical capacities and being physically healthy are the main reasons or motives that justify schools sports practice with over 90% of the answers. However, teachers consider that socialising with friends was the most significant factor.

Conversely, the factor that less influence has for the practice of sports seems to be the same for both groups, namely I like to be popular (approximately 50%), although about half of the students consider that they would like to become stars or sports champions.

The timetables of transportation of students to competitions is one of the critical aspects relating to the quality of the service, although this is more evident in teachers (almost 40% and dissatisfied or very dissatisfied) than in students (20%).

In general, students and teachers are satisfied with the running and the pertinence of school sports competitions. However, while students tend to value the respect for sport competition rules, teachers indicate the commitment of students as the most chosen factor (more than 80%).

From a negative point of view, both groups refer the number of competitions during the school year and the quality of refereeing as the main factors for their dissatisfaction, although results are much more evident in the group of teachers.

INTANGIBLE ATTRIBUTES OF THE QUALITY OF THE SCHOOL SPORTS SERVICE: A COMPARATIVE STUDY BETWEEN ATHLETES AND TEACHERS
Soares, J., Antunes, H.
University of Madeira, Portugal

This study is based on the presupposition that physical education students and teachers involved in school sports are the organisational actors that have the greatest responsibility for the success of training and competitions. Thus, and in accordance with the Portuguese Republic’s Physical Activity and Sports Act (Law n. 5, 2007), school sports should value the participation of young athletes and that of members of the organisation in the assessment and improvement of the service.

This study aims at comparing the perception of athletes with that of the school sports teachers with regard to: the reasons that motivate students to take part in school sports; the easiness in participating and the level of satisfaction in relation to how competitions take place.

For the collection of data two questionnaires were used, put together departing from a study carried out in mainland Portugal (Correia & Rosado, 2006) and adapted to Madeira in accordance with its activity programme (GCDE, 2006). Data processing was done via SPSS version 15 using non-parametric Qui-square and Kruskal - Wallis (p = 0,05) techniques.

The results of the students’ group reveal that enjoyment, the improvement of physical capacities and being physically healthy are the main reasons or motives that justify schools sports practice with over 90% of the answers. However, teachers consider that socialising with friends was the most significant factor.

Conversely, the factor that less influence has for the practice of sports seems to be the same for both groups, namely I like to be popular (approximately 50%), although about half of the students consider that they would like to become stars or sports champions.

The timetables of transportation of students to competitions is one of the critical aspects relating to the quality of the service, although this is more evident in teachers (almost 40% and dissatisfied or very dissatisfied) than in students (20%).

In general, students and teachers are satisfied with the running and the pertinence of school sports competitions. However, while students tend to value the respect for sport competition rules, teachers indicate the commitment of students as the most chosen factor (more than 80%).

From a negative point of view, both groups refer the number of competitions during the school year and the quality of refereeing as the main factors for their dissatisfaction, although results are much more evident in the group of teachers.
Introduction.
A surprisingly large reduction in blood lactate concentration ([lac-B]) is commonly observed during whole body exercise following inspiratory muscle training (IMT). However, Wetter and Dempsey (2000) argue that the size of the respiratory muscles precludes them from affecting systemic [lac-B]. We recently showed Johnson et al (2006) that voluntary hyperpnoea during exercise at maximal lactate steady state (MLSS) increased [lac-B] by 25%.

The aims of this study were to explore whether IMT attenuates such a response and to reveal further the potential of the respiratory muscles to influence systemic lactate kinetics.

Methods.
22 healthy males were divided equally into an IMT group and a control group. Prior to and following a 6-wk intervention period, subjects completed 20 experimental trials at MLSS. Arterialised venous blood was sampled every 2 min to determine [lac-B] and acid-base balance. Respiratory variables were measured breath by breath. The second experimental trial was identical to the first except from min 10 to 20 volitional hyperpnoea was performed. During this period IR was controlled using a metronome and a target VE (95% maximal exercise VE) and VT were maintained via visual feedback. IMT was performed using a pressure-threshold loading device comprising 30 inspiratory efforts twice daily, 7 d/wk, at an intensity of 50% maximal inspiratory mouth pressure (MIP). The control group performed no IMT.

Results. Brachial and popliteal artery FMD or CADC did not change in control subjects at any time points. Exercise training induced changes in brachial artery FMD [ANOVA, P<0.05]. FMD increased from baseline (5.9±0.5%) at weeks 2 and 4 (9±0.6, 8.4±0.6, respectively, P<0.01), but not between baseline and week 8 (6.9±0.7%). Brachial artery CADC analysis revealed a gradual increase throughout training [ANOVA, P<0.01], with an increase from baseline (8.1±0.4%) at weeks 2, 4, 6 and 8 (9.2±0.6, 9.9±0.6, 10±0.5, 10.5±0.8, respectively, P<0.05). In keeping with these results, popliteal artery FMD showed a change during training [ANOVA, P<0.001], with increased FMD between baseline (8.2±0.7%) and weeks 2, 4 and 6 (9.1±0.6, 9.5±0.6, 7.8±0.5, respectively, P<0.05), but not between baseline and week 8 (6.5±0.6%). Popliteal CADC demonstrated a gradual increase in response to exercise training [ANOVA, P<0.05] with significant increase from baseline (8.9±0.4%) at weeks 4 and 8 (10±0.7, 12±0.6, respectively, P<0.05).

Conclusions. This study is the first demonstration in humans of the rapidity and complimentary adaptations in arterial structure and function. Functional changes precede structural adaptations, suggesting that structural change may normalise shear, returning artery function to baseline. These findings may therefore explain why previous pre-and post-exercise training measures have failed to demonstrate any change in functional adaptations.

INSPIRATORY MUSCLE TRAINING REDUCES BLOOD LACTATE CONCENTRATION DURING STEADY STATE EXERCISE AND VOLITIONAL HYPERPNOEA

Brown, P., Johnson, M., Sharpe, G.
Nottingham Trent University, United Kingdom

Aims.
To investigate the effect of inspiratory muscle training on lactate kinetics during exercise following voluntary moderate hyperpnoea.

Methods.
23 healthy males were divided equally into an IMT group and a control group. Prior to and following a 4-wk intervention period, subjects completed 20 experimental trials at MLSS. Arterialised venous blood was sampled every 2 min to determine [lac-B] and acid-base balance. Respiratory variables were measured breath by breath. The second experimental trial was identical to the first except from min 10 to 20 volitional hyperpnoea was performed. During this period IR was controlled using a metronome and a target VE (95% maximal exercise VE) and VT were maintained via visual feedback. IMT was performed using a pressure-threshold loading device comprising 30 inspiratory efforts twice daily, 7 d/wk, at an intensity of 50% maximal inspiratory mouth pressure (MIP). The control group performed no IMT.

Results. Brachial and popliteal artery FMD or CADC did not change in control subjects at any time points. Exercise training induced changes in brachial artery FMD [ANOVA, P<0.05]. FMD increased from baseline (5.9±0.5%) at weeks 2 and 4 (9±0.6, 8.4±0.6, respectively, P<0.01), but not between baseline and week 8 (6.9±0.7%). Brachial artery CADC analysis revealed a gradual increase throughout training [ANOVA, P<0.01], with an increase from baseline (8.1±0.4%) at weeks 2, 4, 6 and 8 (9.2±0.6, 9.9±0.6, 10±0.5, 10.5±0.8, respectively, P<0.05). In keeping with these results, popliteal artery FMD showed a change during training [ANOVA, P<0.001], with increased FMD between baseline (8.2±0.7%) and weeks 2, 4 and 6 (9.1±0.6, 9.5±0.6, 7.8±0.5, respectively, P<0.05), but not between baseline and week 8 (6.5±0.6%). Popliteal CADC demonstrated a gradual increase in response to exercise training [ANOVA, P<0.05] with significant increase from baseline (8.9±0.4%) at weeks 4 and 8 (10±0.7, 12±0.6, respectively, P<0.05).

Conclusions. This study is the first demonstration in humans of the rapidity and complimentary adaptations in arterial structure and function. Functional changes precede structural adaptations, suggesting that structural change may normalise shear, returning artery function to baseline. These findings may therefore explain why previous pre-and post-exercise training measures have failed to demonstrate any change in functional adaptations.

RELATIONSHIP BETWEEN THE CATECHOLAMINES AND HEART RATE VARIABILITY (HRV) RESPONSE DURING CYCLING AT MAXIMAL LACTATE STEADY STATE (MLSS)

UNIVERSIDAD POLITECNICA DE MADRID, Spain

INTRODUCTION
During submaximal steady-state (SS) exercise the adrenaline and noradrenaline concentration are supposed to increase continuously 1, 2, being an indicator of the sympathetic activation 6. Differents studies have shown relations between sympathetic and parasympathetic activity and the different spectral components of HRV 6. The aim of this study was to compare the catecholamines and HRV response at the MLSS in cycling, to differentiate the nervous activity during exercise.

MATERIAL AND METHODS
Twelve amateur cyclists participated in the study [21 ± 2.6 years, 179.8 ± 7.5 cm, 72.2 ± 9 Kg]. Each subject performed an incremental test (25 W o min⁻¹) until exhaustion on a cicloergometer, and two 30 minutes constant load tests to determine the MLSS 3, 4 at an intensity around the mean point of ventilatory thresholds (VT). Expired air was analyzed with a Jaeger Oxycon Pro. Arterialized venous blood samples were obtained at 0, 10, 20 and 30 minutes during the SS tests. Lactate concentration [L-] and catecholamines concentration were determined. The heart rate (HR) was obtained from a Polar HR monitor and HRV was measured using HRV analysis software. A one way ANOVA was used to compare the response of the variables in 0, 10, 20 and 30 minutes and Pearson correlation analysis was used to set the relationships between variables. The significant level was set at 0.05.<ref>RESULTS</ref>

The VO₂ during MLSS was 4225.17±414.39 mL/min (58.82±4.67 mL/min/kg) and 81.84±7.02 %VO₂max. The workload was 279±28 W. The main significant correlations were obtained between [L-] and noradrenaline concentration [Nor] and HR (r=0.855 and r=0.835 respectively), [Nor] and HR (r=0.852), high frequency (HF) and low frequency (LF) and very high-frequency (VHF) (r=0.894 and r=0.839 respectively). There were not significant correlations between hormones concentration and HRV variables. Significant differences were found between 0 minute and 10, 20 and 30 minutes in almost all variables along the MLSS (p<0.05). Hydrogen ion concentration [H⁺], [L-] and adrenaline concentration were stable (10, 20 and 30 minutes), while HR and [Nor] increased from 10 minute to 30 minute (p<0.05). LF, HF and VHF decreased from 10 minute to 30 minute (p<0.05).

DISCUSSION
HR and [Nor] did not stay stable during the MLSS test, due to the “cardiovascular drift” and the increase in sympathetic nervous system activity 2, 5. However, our results sugest there is no relation between catecholamines and HRV during the MLSS. Thus, the use of HRV is not clear to differentiate the nervous activity during MLSS6.

BOTOX INDUCED MUSCLE PARALYSIS LEADS TO SLOWER MYOSIN HEAVY CHAIN ISOFORMS AND REDUCES TITIN CONTENT

Legerlotz, K., Matthews, K., McMahon, C., Smith, H.
1) University of Auckland, Auckland 2) AgResearch, Ruakura Agricultural Centre, Hamilton, New Zealand

Introduction
Botox and exercise are both applied in the therapy of spastic muscle in children with cerebral palsy. However, little is known about the biological changes in muscle composition following Botox injections and how the combination of Botox and exercise affects the growing muscle. Muscle function is determined in large part by the contractile protein myosin and the structural protein titin. The purpose of this study was therefore, to determine the effect of Botox and 3 weeks of exercise on the myosin heavy chain isoform and titin.

Methods
Male Sprague-Dawley rats (29 d, 74 ± 4 g) were randomly assigned to four groups (n=6) that received either saline or Botox (Btx) injections in the right gastrocnemius muscle: 1) sedentary control group (Con), 2) wheel-running group (Ex), 3) Btx-paralyzed sedentary group (Btx), 4) Btx-paralyzed wheel running group (Btx-Ex). The animals of the exercise groups had free access to running wheels and the frequency, velocity and distance of all voluntary running bouts were recorded continuously. After 3 weeks, the animals were sacrificed. The gastrocnemius muscle was dissected, frozen in liquid nitrogen and stored at -80°C. Frozen muscles were homogenized in low salt lysis buffer and total protein was isolated. Protein concentration was determined by optical densitometry and equal amounts of protein were buffer and total protein was isolated. Protein concentration was determined by optical densitometry and equal amounts of protein were

RESULTS
The mean daily running distance in Ex (776 ± 538 m) did not differ significantly from Btx-Ex (636 ± 37 m). Botox decreased gastrocnemius mass (Btx-Ex -43%, Btx -46%), while exercise increased gastrocnemius mass, expressed relative to body mass, only in Ex (+6%) and the contralateral leg of Btx-Ex (+8%) compared to Con. Botox had an effect on muscle composition, since the percentage of MHC type IIB decreased, while the slower MHC type IIX increased. This effect was slightly enhanced by exercise. The titin content, represented by the band volume, decreased with Botox (-25%). Furthermore, there was a tendency for exercise to enhance the effect of Botox, since the lowest titin content was found in exercised muscle that received Botox injections.

Discussion
Our results add to the limited knowledge that Botox affects MHC expression different than other forms of paralysis, since in contrast to our findings changes towards a faster muscle phenotype have been observed in spinal cord injury patients. This is the first evidence to sug-
gest a Botox-exercise effect on MHC and titin, indicative that exercise of Botox paralysed muscle, as done in therapy, might induce adaptations different from that in non-Botox muscle. Thus, caution may be warranted in the use of physiotherapeutic therapy in Botox paralysed muscle.

REPETITION FAILURE IS NOT REQUIRED FOR MAXIMAL STRENGTH ADAPTATION

Sampson, J., Groeller, H., McAndrew, D., Britton, A., Taylor, N.
University of Wollongong, Australia

Resistance training protocols targeting maximum strength adaptation commonly encourage exercise to repetition failure. Loads greater than 85% of one repetition maximum (1RM) promote maximal strength adaptation, whilst explosive exercise against relatively lighter loads increases the rate of force development. We hypothesised resistance exercise to repetition failure is unnecessary when heavy loads (85% 1RM) are attempted as an explosive resistance exercise. Therefore, we investigated neuromuscular adaptation of the biceps brachii in untrained males (N=28) using three elbow flexion (60°-160°) treatments: (EC) attempted explosive concentric and eccentric; (SSC) attempted explosive concentric and eccentric; and (C) controlled 2-s concentric and eccentric training. All subjects completed a 4-wk progressive resistance training (control) period prior to the experiment. Subjects then exercised a further 3 days per wk for 12 wks at 85% 1RM. Group (C) performed four sets to repetition failure, completing 6.1 ±0.1 repetitions per set. The two explosive exercise groups performed four sets: (EC) 4.2 ±0.1 and (SSC) 4.2 ±0.0 repetitions. Strength was assessed isometrically (7 angles: 80°-140°) and via a 1RM elbow flexion, and muscle cross-sectional area using magnetic resonance imaging. Filtered electromyographic (EMG) data were sampled at 2 kHz (Digitimer, Neurolog). Peak and average root mean square (RMS) and mean frequency (Wf, Spike 2 Ver5.13) were calculated over scroling 250 ms windows with a 50% overlap. All data are means ±SE with alpha set at 0.05. Despite a 31% reduction in total work, no significant differences were observed in 1RM strength gain among groups: (EC) 28.17% (6.28±0.46kg), (SSC) 34.22% (6.28±0.32kg) and (C) 29.43% (5.85 ±0.63kg). Significant training-induced increases in peak RMS (EC: 8.34 ±5.06%, SSC: 20.42 ±12.2%, C: 21.79 ±13.31%) and mean RMS (EC: 7.66 ±5.1%, SSC: 46.97 ±21.8%, C: 16.71 ±11.2%) were observed during 1RM, but significant differences among groups were not detected. Significant increases in MVC were observed at joint angles between 80-120° in all groups. Our results demonstrate that it is not necessary to achieve repetition failure for maximal strength adaptation when high attempted velocity movements are coupled with higher loads. This may result from an optimal neuromuscular adaptation associated with altered motor unit recruitment thresholds and increased motor unit firing during explosive muscle contractions (Van Custem et al. 1998), or possibly differences in the rate of muscle hypertrophy.

THE EFFECT OF PLYOMETRIC EXERCISE ON PERCEIVED EXERTION AND CYCLING ENDURANCE PERFORMANCE

Twist, C., Eston, R.
University of Chester/University of Exeter, United Kingdom

The effects of exercise-induced muscle damage on endurance performance have been studied infrequently. The purpose of this study was to evaluate the effects of exercise-induced muscle damage on the cardiovascular, metabolic and perceived exertion responses to fixed-load exercise and 5-minute time-trial performance. Following ethical approval, seven recreational athlete volunteers (age 22.1 +/- 3.9 y, stature 1.76 +/- 0.08 m, body mass 76.0 +/- 4.2 kg) performed an incremental test to exhaustion on a cycle ergometer to determine VO2peak and the power output corresponding to VO2peak (Pmax). After a minimum of 96 h, participants performed two fixed-load exercise bouts, exercising at 60%Pmax and 80%Pmax followed by a 5-minute time-trial. Cardio-respiratory, metabolic and perceived exertion responses were recorded during all tests. Performance measures were accompanied by measurement of perceived muscle soreness and peak isokinetic torque of the knee extensors at 60 deg/s. Following a further 48 h, participants performed muscle-damaging exercise consisting of 10 x 10 plyometric jumps, after which all measurements were repeated at 48 h and 168 h. Indirect evidence of muscle-damage following plyometric exercise was confirmed by a significant increase in perceived muscle soreness and concomitant reduction in peak isokinetic torque at 48 h (P<0.05). There were no significant main effects for time (P>0.05) or time by exercise intensity interactions (P>0.05) on VO2peak, heart rate, RER, and blood lactate concentration during the 60% and 80%Pmax fixed load bouts. However, Ve and Ve/VO2 were significantly increased at 48 h (P<0.05) at 48 h. RPE values were also increased following plyometric exercise (60%Pmax: 13.7 +/- 0.4, 15.4 +/- 0.7 and 12.9 +/- 0.4, 80%Pmax: 17.7 +/- 0.5, 18.3 +/- 0.5 and 16.7 +/- 0.3 at baseline, 48 and 168 h, respectively, P<0.05). The ratio of RPE-HR and RPE-VO2 were also higher at both exercise intensities at 48 h (P<0.05). With regard to the 5-min time trial performance, peak VO2, mean VO2, peak power output, mean power output, distance covered and post exercise blood lactate were significantly lower at 48 h after the muscle-damaging plyometric exercise bout (P<0.05). However, the absolute RPE values remained the same between trials (P>0.05). These findings indicate that the ventilatory equivalent for oxygen and the rating of perceived exertion at submaximal work rates are increased 48 h after performing a single session of plyometric exercise. We also conclude that exercise-induced muscle damage impairs time-trial performance, increases perceived exertion and decreases the amount of work that can be completed in a 5 minute all-out effort.

ASSESSMENT OF THE EFFECTS OF AN 8-WEEKS CONDITIONING PROGRAMME ON MUSCULAR STRENGTH: COMPARISON BETWEEN WHOLE BODY VIBRATIONS, CONVENTIONAL STRENGTH TRAINING

Preadtoni, E., Colombo, A., Verga, M., Galvani, C., Faina, M., Cardinali, M., Rodano, R., Preadtoni, E.
Politecnico di Milano, Italy

Introduction

Whole body vibration (WBV) may represent an alternative exercise intervention for enhancing strength and power in humans. Many authors have studied the effects of WBV on the neuromuscular and neuroendocrine system [1]. However, it is still not clear if and how they may be beneficial for elite athletes.
Therefore, the aim of this work was to compare the effectiveness of similar training programmes, carried out through WBV, traditional weights or their combination. Their influence on muscular strength was assessed in a population of male athletes.

Methods

18 healthy competitive female athletes (23.8±4.6 y; 1.6±0.05 m; 58.8±7.8 kg) were randomly assigned to 3 training groups (V, B and VB). They carried out a periodised 8-weeks training programme, 2 cycles of 3 weeks with 2 training session a week, followed by a week of tapering. During each training session, subjects performed 6 sets of 6 repetitions of dynamic training: on a vibrating platform (Nemes LX-B, SAIR, Italy) [V], with a weight loaded barbell (B); with a weight loaded barbell on a vibrating platform (VB). Vibration frequency was initially set at 25 Hz and was increased by 5 Hz every 2 weeks for both V and VB. Bar loads were set at 60% and 30% of each subject's body mass (BM) for B and VB, respectively, and was increased of about 3% (for VB) and 6% BM (for B) every 2 weeks. Isometric and dynamic muscular strength was measured before and after the training period. Maximal voluntary contraction (MVC isometric) was measured by force platforms (Twin Plates, Globus, Italy), fixed onto the footplate of a leg press. The seat was locked so that the subject's knees were flexed at 90 deg. Dynamic variables (force, velocity and power) were calculated from force platforms and linear encoder measurements. Muscle's laws (Real Power, Globus, Italy). The external loads used for dynamic measurements corresponded to 100-120-140-160-180-200% BM. Non-parametric within groups tests (Wilcoxon) and repeated measure ANOVA were applied (P=0.05) where appropriate, after applying normal distribution tests.

Results

Isometric tests manifested statistically significant changes only in group V, for which T30 and T50 (respectively, time to 30 and 50% of MVC) increased from 64 (17) ms and 92 (16) ms, to 72 (16) ms and 100 (31) ms [median (IQR)]. No main effect for treatment was identified in all other measurements.

Discussion

WBV did not seem to induce enhancements in either static or dynamic muscular force, either alone or in combination with low intensity resistance exercise with the protocols used in our study.

EFFECTS OF COMPRESSION GARMENTS ON EXERCISE PERFORMANCE AND RECOVERY FOLLOWING INTERMITTENT, HIGH-INTENSITY EXERCISE

King, M., Duffield, R., Rouse, M.
Charles Sturt University, Australia

Compression garments are commonly used as both a performance and recovery aid despite inconclusive evidence to support their effectiveness to perform either function. The aim of this study was to determine the effects of wearing compression garments (CG) (Slazenger) on performance and physiological responses during and following intermittent, high-intensity cycling exercise. Eight male and seven female team-sport athletes performed an initial familiarisation session followed by two testing sessions either with or without CG i.e. during a 30-min exercise protocol and for a 60min post-exercise recovery phase, participants were required to wear either full-body CG or normal athletic clothing. Each testing session consisted of a 30min high-intensity, intermittent-sprint cycling protocol involving a 20s maximal sprint every 5min, separated by a constant-intensity of 100W. Peak power (Watts) and time to peak power (sec) were recorded for each sprint effort, with the % decrement in power calculated as an indicator of maintenance of sprint performance over the seven sprints. A measure of maximal voluntary contraction (MVC) and evoked twitch properties (Pf), and a capillary blood sample (for lactate, pH and HCO3) were obtained pre and immediately, 15-, 30- and 60-min post-exercise. Further, during and following exercise VO2, core temperature (Tc), heart rate (HR) and rating of perceived exertion (RPE) measures were obtained. Results for exercise performance indicated no significant differences (p=0.40-0.90) between conditions for peak power, time to peak power or % decrement in peak power. Further, the reduction and subsequent recovery of MVC and Pf was not changed with CG (p=0.05). Whilst not significant, moderate to large effect sizes (d=0.5-0.8) for a reduced VO2 in the CG condition compared to the control condition were evident. There were no significant differences between the conditions for HR, Tc, change in nude body mass or blood measures. Finally, immediately and 60-min post-exercise, a moderate effect (d=0.50, P=0.20) for a reduced self-reported RPE was observed when wearing the CG. In conclusion, minimal differences between conditions for exercise performance, recovery of evoked or voluntary muscle performance or physiological responses were present. However, VO2 at a sub-maximal, constant-intensity of 100W was reduced in the CG condition indicating an improved economy of effort when cycling in the garments. Given the lack of differences in HR, this may indicate the elastic recoil of wearing the garments, improved economy of effort when cycling in the garments highlighting the possible perceptual benefits of wearing the garments, despite no differences in anaerobic metabolic markers. Overall, these results may indicate the effectiveness of the garments to improve economy and subjective accounts of recovery when worn during or following exercise.

RELATIONSHIP BETWEEN TACTICAL SKILLS AND PERFORMANCE LEVEL OF EXPERT YOUTH SOCCER PLAYERS

Kannekens, R., Efferink-Gemser, M., Visser, C.
University Medical Center Groningen, Netherlands

In invasion games, such as soccer, athletes need well-developed tactical skills. Studies with novice and expert athletes show that expert athletes outscore novice athletes on aspects of tactical skills. Unknown is whether this relation also holds when all athletes are experts. Therefore, the aim of this study is to determine if there is a relationship between tactical skills and level of performance in a population of all expert youth soccer players.

The tactical skills inventory for sports (TACSIS, Efferink-Gemser et al., 2004) with questions related to declarative (‘knowing what to do’) and procedural knowledge (‘doing it’) was used to measure tactical skills of 37 soccer players of the Dutch (n=18, age: 19.5±2.0 16-18 years) and Indonesian (n=19, age: 20.6±2.16 years) national youth team. Participants were all expert players although the Dutch team has a higher performance level than the Indonesian team. Players were also divided per team on the basis of playing minutes at an international soccer tournament.

Analyses of variances showed that the Dutch players outscored the Indonesian players on ‘knowing about ball actions,’ ‘knowing about others’ (declarative knowledge), and ‘positioning and deciding’ (procedural knowledge) (p<.05). Within the Dutch national team there was no relation between playing minutes and tactical skills. Within the Indonesian national team there was a positive relation between playing minutes and positioning and deciding (p<.05).
The explanation of the Dutch players outscoring the Indonesian players on several aspects of tactical skills might be that they are playing for a longer period of time at a higher performance level (Dutch starting age: 5.24±1.09 years; Indonesian starting age: 9.12±2.58 years). As performance level increases, the necessity of performing the right action at the right moment also increases. In soccer, when time is constrained knowing what to do and doing it is essential for a successful outcome. The explanation of the lack of relation within the Dutch national team between playing minutes and tactical skills might be that on a high performance level other aspects than tactical skills are important for a trainer to decide which players are lined up. As performance level decreases, tactical skills also decrease. It could be that the Indonesian players with the minimum playing minutes know what to do, but lacking the skills for doing it (French et al., 1987, Thomas et al., 1994, McPherson, 1994). In conclusion, this study shows that there is a positive relationship between tactical skills and level of performance also within a population of all expert players.

VALIDITY OF A RESPIRATORY SNORKEL FOR DETERMINATION OF OXYGEN UPTAKE KINETICS IN SWIMMING

Reis, J., Millet, G., Vleck, V., Alves, F.
Faculty of Human Kinetics - Lisbon, Portugal

In pursuit of direct measurement of cardio-respiratory parameters in swimming Toussaint et al. (1987) developed a respiratory and valve system that was shown to be valid and to only slightly increase the hydrodynamic drag. The more recent version of this respiratory snorkel (RS) (Aquatrainer, Cosmed, Roma, Italy) connected to a breath-by-breath (BxB) gas analyser (K4b2, Cosmed, Roma, Italy) was evaluated by Rodriguez et al. (2008). It was reported that although the FiO2 was significantly larger when measured with the RS, there were no significant differences in VO2 and VCO2 between the RS and a mechanical gas exchange simulation system. However, in what concerns oxygen uptake kinetics, the use of the RS has not yet been evaluated.

The purpose of this study was to compare the parameters of the VO2 kinetics in constant-power exercise, using a conventional face mask (CM) or a respiratory snorkel (RS) designed for breath-by-breath analysis in swimming. Ten trained triathletes (29.3±8.3 yrs; 67.5±7.3 kg, 177.2±6.9 cm) performed two testing sessions involving a incremental test to exhaustion for determination of VO2max and Ventilatory Threshold (VT1) and two 8-min constant load exercise at 25% = VT1 + 0.25 x (VO2max - VT1) in each condition. The VO2 kinetics parameters (td1, tau1, A1, td2, tau2, A2, i.e. time delay, time constant and amplitude of the primary phase and slow component, respectively) were modelled with two exponential functions (Borrani 2001), which also incorporated the determination of an individual snorel delay (ISD) in the case of the RS tests. This time was calculated as the difference between the start of the exercise and the time when the following breaths summed a tidal volume superior to the outlet tube volume, therefore making the VO2 data to be exercise representative. Only td1 was significantly different between RS and CM (13.8±s.1,77 and 8.95±s.2,99 s, respectively) due to the delay introduced by the tubing. Otherwise the parameters variability of the primary phase parameters wasability not different between RS and CM.

In conclusion, direct measurement of VO2 in swimming for estimating VO2 kinetics is appropriate and comparable to terrestrial activities (i.e. running, cycling), as long as a suitable numerical method is used to model the data, since the use of a respiratory snorkel does not interfere with the kinetic parameters obtained in heavy intensity constant load exercise.

DRIBBLING AS PREDICTOR OF FUTURE SOCCER PERFORMANCE

Huijgen, B., Ellerink-Gemser, M., Visscher, C.
University Medical Center Groningen, Netherlands

To reach the top in soccer, technical skills are of extreme importance. The current study focuses on the development of dribbling with quick changes of direction, since this is recognized as a central component in the development of young players (Malina et al. 2005,Reilly et al. 2000). To predict long-term success within a group of talented youth soccer players, longitudinal tracking is needed. The goal of the present study is to reveal whether the technical performance characteristics of dribbling and the factors underlying this technical skill are predictive for future playing level.

A total of 134 talented soccer players from soccer schools in the Netherlands age 14-18 were tested, 237 measurements were performed. The players tested are currently 20 years or older and are classified into their current playing level: professional (N=31), semi- (N=49) or non-professional (N=54) players. The Shuttle Dribble Test was used to measure the development of dribbling performance in a longitudinal study over 5 years. The test consisted of a maximal sprint of 30 m while dribbling a soccer ball (Lemmink et al. 2004). The 30 m sprint has three 180° turns, measuring the acceleration of soccer players. Anthropometrics (height, weight, and body fat percentage), and training characteristics were assessed. Longitudinal changes in dribbling were investigated using the linear mixed model procedure in SPSS.

The fixed part of the multilevel model contains a different intercept term for the current playing level (semi-professionals + 0.07 seconds and non-professionals + 0.17 seconds compared to professionals). The multilevel age-model showed better performance of the current professional players compared to the current lower level players at age 15, 16 and 17 on the Shuttle Dribble test (p < 0.05). The age-model was significantly improved by including lean body mass and total practice hours per week, both having a positive effect on dribbling performance.

Although soccer performance can be divided into many multidimensional performance characteristics (Ellerink-Gemser et al., 2004), the current results showed that dribbling performance in youth can be an useful tool for identifying the best players for the future. Current professional players outscored current semi- and non-professional players in dribbling during adolescence, especially from age 15-17. More lean body mass and extra practice hours positively influence dribbling performance. The Shuttle Dribble test illustrated to be a good predictor for future playing level.
CONTRIBUTIONS OF SELECTED FUNDAMENTAL FACTORS TO ATHLETICS PERFORMANCE IN ADULT INDIVIDUALS WITH MENTAL RETARDATION

Franciosi, E., Guidetti, L., Gallotta, M., Emerenziani, G., Baldari, C.
Istituto Universitario di Scienze Motorie, Italy

Regular physical activity is encouraged as being important for preventing diseases and promoting physical and emotional well-being for individuals with Mental Retardation (MR) [Fragala-Pinkham et al, 2005; Carmeli et al, 2005], but it is well known that people with MR exhibit poor fitness performance on standard fitness tests (Graham and Reid, 2000). The aim of this study was to determine the contributions of selected fundamental factors to athletic performance in adult individuals with MR.

Thirty-two trained athletes with MR (20 males and 12 females, age range 20-45 years, MR levels: 7 Mild, 3 Moderate-Mild, 8 Moderate, 4 Moderate-Severe, 8 Severe and 2 Profound) were recruited. The athletes’ performance was assessed using the official results in an Individual Athletics Championships. The athletes could take part in one or two competitions selected within one of the two ability levels: Level I (60m, 300m, 400m in walking, Standing Long Jump, and Vortex Throw) or Level II (100m, Shot Put, and Long Jump). The fundamental factors included anthropometric measurements (height, weight and %body fat), flexibility assessed by Sit and Reach test, standing balance assessed by Flamingo test, muscular endurance assessed by Push-ups and Sit-ups tests, leg muscular strength assessed by Standing Long Jump test, cardiovascular endurance (VO2max) assessed by Step test and coordination assessed by Timed Get-Up and Go test. Stepwise regression analysis was used to identify the contribution of these selected fundamental factors to performance. This study showed that in Level I the leg muscular strength and height had significant contributions to 60m (81%), the leg muscular strength and lower %body fat had significant contributions in vortex throw (70%). The coordination, lower %body fat and flexibility had high significant contributions in Standing Long Jump performance (90%). Within Level II, the leg muscular strength and a lower MR level had significant contributions in 100m (85%). Lower weight had high significant correlation in Long Jump scores (P<0.01). Lower age and cardiovascular endurance had high significant contributions in Shot put (98%).

It was possible to predict the efficiency of athletics performance in Level I by leg muscular strength, flexibility and coordination. In Level II, cardiovascular endurance and anthropometric measurements were especially important to improve athletes’ performance. All these selected fundamental physical factors should be addressed in athletics training for adult individuals with MR.

PS-1 Genetics: The impact of molecular technology on the future of sports

CATCHING UP WITH WINNERS IN THE GENETIC LOTTERY? FAIR OPPORTUNITY IN SPORT

Loland, S.
The Norwegian School of Sport Sciences, Norway

The structural goal of sport competition is to measure, compare and rank participants according to athletic performance. In this sense, sport deals with inequalities between persons. The critical question is whether all kinds of inequalities are of relevance to sport. Should some inequalities be eliminated or compensated for, and if so, which ones and why?

Athletic performances are complex products of a high number of genetic and extra-genetic factors with impact from the moment of conception to the moment of performance.

Genetic factors can be understood as genetic predispositions for developing relevant abilities and skills to athletic performance. A person with good predispositions is usually characterized as ‘talented’. Genetic talent is distributed in the so-called natural lottery and based on chance.

Athletes develop talent through gene-gene-environment interaction. Impact from environmental factors ranges from the more indirect influence on performance from the material, economic and socio-cultural contexts of which athletes are parts, to specific training and learning of technical and tactical skills of particular sports. Impact from environmental factors is in part outside of and in part within athlete control.

The fair opportunity principle (FOP) is introduced as a regulative principle in this respect. In its general form, FOP prescribes eliminating or compensating for inequalities in essential qualities which individuals can not influence or control in any significant way and for which they therefore can not be held responsible (Rawls 1971). In its sport-specific version, FOP(S) prescribes the elimination of or compensation for inequalities with significant and systematic impact on athletic performance that individuals can not influence or control in any significant way and for which they therefore can not be held responsible (Loland 2002).

It is argued that FOP(S) has radical consequences for competitive sport both in terms of eliminating or compensating for inequalities in talent (genetic predispositions), and inequalities in environmental factors. A series of proposals are made on how to raise the level of fair opportunity in current sport. Among the proposals are a revision of existing classification systems, and rules to reduce the impact of inequalities in athletes’ supporting systems. Particular emphasis is put on discussing inequalities in genetic talent, and inequalities due to the use of doping and bio-technical means.
INVESTIGATING THE GENETIC BASIS OF PHYSICAL ACTIVITY RELATED TRAITS

Wareham, N.
MRC Epidemiology Unit, United Kingdom

The epidemiology of many emerging chronic diseases suggests that interactions between genetic predisposition and lifestyle behaviours such as physical activity are central to disease causation. Such a proposition is easy to make, but the task of identifying the molecular basis of such interactions is much harder. Progress in discovering main effects for various chronic metabolic disorders including obesity and type 2 diabetes is accelerating thanks to the output of whole genome association studies, demonstrating the limitations of previous candidate gene approaches. A range of possible study designs is available for investigating gene-physical activity interaction, each with different strengths and weaknesses. However, given the likely small main effect of common genetic variants, an analytical approach based on the clear specification of prior probabilities to reduce the chance of false discovery is likely to be preferable. Mixed approaches combining data from large-scale observational studies with smaller intervention trials may be ideal. In designing new studies to investigate these issues, a key choice is how to quantify physical activity as it is clear from power calculations that the precision of measurement of this key exposure is critical to the ability to detect interaction.

IS-BN02 Neuromechanics in aging

AGING-INDUCED NEURAL ADAPTATIONS IN HUMAN GAIT

Hortobágyi, T., Solnik, S., Rider, P., Moscicki, B., Lin, P., Bai, O., Hallett, M., DeVita, P.

East Carolina University, United States

Advancing age brings about profound changes in human locomotion due to modifications in the properties of bone, muscle, and tendon. There is also increasing evidence to suggest that age-related changes occur in the central nervous system, including a loss of motor units, cortical and spinal motor neurons, and muscle spindles accompanied by a diminishment of corticospinal and spinal reflexes, factors that can affect the neural control of gait. Here we examine the possibility that advancing age affects the shared synaptic input to pairs of muscles during gait. The pairs of muscles that are examined are the tibialis anterior and gastrocnemius lateralis during ascending and descending gaits and gaits at slow and fast speeds. The differences were statistically larger at frequencies up to 22.5 Hz (or alpha band), coherence thought to be of spinal origin (3) and smaller at higher frequencies (beta and gamma). These data agree with reduced coherence between single motor units (4) and the concept that advancing age may affect the coordination between excitatory and inhibitory activity of neural oscillators (5). Future research will determine if such impairments have functional consequences such as reduced adaptive walking skills in old vs young adults.

AGING-RELATED ISSUES IN MOTOR UNIT DISCHARGE BEHAVIOR

Kamen, G.

University of Massachusetts - Amherst, United States

There are numerous morphological changes in the aging motor system and these are accompanied by alterations in the manner in which motor units are activated. With advancing age, muscle fibers decrease in size. The numbers of motor units decreases as a result of motor unit atrophy. Surviving muscle fibers may be re-recruited by other motor neurons producing very large motor units composed predominantly of slow-twitch muscle fibers. Although individual muscle fiber twitch forces are smaller, the resultant increase in motor unit size can produce very large motor unit twitch forces. The increase in motor unit size can be documented using macro EMG techniques. Surviving motor units exhibit smaller maximal firing rates, and this is true in both small muscles as well as large muscles. Mechanisms producing the reduction in maximal firing rate might include reduced motor neuron excitability caused by a reduction in tonic activity at spinal levels or impaired activation at cortical levels. There are also changes in motoneuron action potentials such as the afterhyperpolarization that may be implicated in the attenuated firing rate. Motor unit firing variability has also been assessed, though the results appear somewhat equivocal. A potential strategy for augmenting force, doublet firing, is reduced in frequency in older adults. Motor unit synchronization, the tendency for pairs of motor units to fire simultaneously, appears to occur with similar frequency in both young and older adults. These and other characteristics of age-related motor unit discharge behavior will be discussed in the presentation.

AGING-INDUCED NEUROMUSCULAR INTERACTION AND TRAINING ADAPTATION DURING NORMAL HOPPING

Ishikawa, M., Hoffrén, M., Komi, P., Masaki, V.

Osaka University of Health and Sport Sciences, University of Jyväskylä, Japan

It is well known that aging influences neuromuscular function. Literature is quite abundant regarding the deterioration of muscle strength, which is most evident after 50 years of age. This is usually associated with reduction in number of skeletal muscle fibers and motor units. The resulting sarcopenia will in turn be responsible for reduction in optimal bone loading and the situation may then lead to deterioration of the bone structure. All these events are partially responsible for age related problems in body control during movement including risks for falls and accompanied bone fractures. Recent ultrasonographic studies give convincing evidence that on the muscular level the fascicle length and pennation angle decrease in aging (4,5). This suggests the loss of sarcomeres both in series and in parallel in aging muscle, which can influence the maximum force as well as shortening velocity of the muscle.
In addition to muscle mechanical properties, the neural activation strategy also plays important role in aging. The measurements of antagonist coactivation have shown increased level of coactivation in elderly individuals during human movements [1,2,3]. Especially, this increased coactivation may affect the joint stiffness in the braking phase of dynamic movements and the movement efficacy. Thus there is considerable need to explore whether there is age-specific activation strategy during dynamic movements together with the regulation of fascicle-tendon interaction.

The basic comparison between YOUNG and OLD subjects showed that the activation strategies in hopping were dramatically different in OLD as compared to YOUNG. OLD demonstrated lower agonist muscle activation in braking phase and higher agonist muscle activation in push-off phase than YOUNG (p<0.05), indicating less utilization of elastic energy. However, when OLD performed repetitive hopping training, they showed already after two weeks modification of the activation strategy to resemble that of YOUNG. Tendon stiffness, as evaluated by high speed ultrasonography, showed also the training induced mechanical adaptations in fascicle-tendon interaction.

IS-PM01 Angiogenesis and exercise

HAEMODYNAMIC FORCES AND SKELETAL MUSCLE ANGIOGENESIS IN EXERCISE

Brown, M., Milkiewicz, M., Hudlicka, O.
University of Birmingham, United Kingdom

The growth of new capillaries occurs in skeletal muscle trained by exercise around the fibre types that have been activated, linking angiogenesis with haemodynamic forces associated with exercise hyperaemia, such as shear stress, and/or metabolic factors relating to contraction e.g. hypoxia and VEGF. The growth takes place by two modes, proliferative sprouting angiogenesis and non-proliferative longitudinal splitting of vessels by formation of intra-luminal endothelial projections. The role of blood flow per se in initiating capillary growth in rodent skeletal muscle is shown by chronic application of a vasodilator (prazosin), which increases capillary shear stress 4-fold and induces capillary growth within days [1] around all fibre types [2]. Growth occurs by longitudinal splitting only [3], and is dependent on nitric oxide (NO) [4] and shear-related up-regulation of VEGF in capillaries [1], in the absence of metabolic stimuli. In exercise, fibre types are recruited in order, with increases in blood flow matching intensity. Studies localising endothelial cell proliferation and VEGF immunostaining to capillaries and fibre types have helped to identify how sprouting and splitting types of angiogenesis might co-exist in exercised muscle. If all motor units are activated by intensive exercise or chronic muscle stimulation, capillary proliferation associated with sprouting is initiated first around fast glycolytic fibres [5]. This is likely due to hypoxia [6] and up-regulation of VEGF in both fast fibres [7] and proliferating capillaries [5]. However, VEGF also increases in non-proliferating capillaries without relationship to fibre type. This could represent shear-induced up-regulation because the microvascular unit, comprising arteriole and capillaries, supplies a group of adjacent muscle fibres, not the spatially dispersed fibres of individual motor units. Hence flow will be directed not only to active muscle fibres but will ‘over-perfuse’ neighbouring non-active fibres [8], and could provoke splitting capillary growth. This flow-related component of angiogenesis does not conform to the concept of physiological vessel growth to meet metabolic needs, but no doubt helps the efficiency of oxygen to tissue transport during muscle contractions [9].

ANGIOGENESIS IN SKELETAL MUSCLE IN RESPONSE TO EXERCISE

Bouch, O., Hoppeler, H.
University of Bern, Switzerland

Mammalian skeletal muscle is composed of a specific mosaic of muscle fibers surrounded by capillaries that provide the tissue with oxygen and nutrition. However the interaction between muscle fibers and capillaries is not static but might undergo changes in response to different stimuli (mechanical, hemodynamic, environmental). In particular, simultaneous increases in the capillary-to-fiber ratio and the capillary density indicate that the capillary system has expanded (a process designated angiogenesis). Over the last 30 years our group has collected about 700 needle biopsies derived from vastus lateralis muscle of human subjects belonging to different study groups. Applying a standardized morphometric protocol on EM level, we were able to quantify the impact of exercise on the capillary supply in skeletal muscle. Because the capillary-to-fiber ratio and capillary density were found to be higher in trained than untrained men, a study was designed in which groups of male and female individuals were subjected to different training protocols over periods of typically six weeks. Angiogenesis in skeletal muscle occurred only in protocols that induced similar rates of mitochondrial growth. It was concluded that the microvasculature density and the metabolic phenotype of muscle fibers are correlated to ensure maximal rates of skeletal muscle oxidation. Further studies showed that the angiogenic response can be further increased if the high-intensity training is performed under hypoxic conditions and that eccentric rather than concentric exercise influences the microvasculature density. Some of the studies
were accompanied by gene array analyses of the mRNA gene expression patterns. The data obtained allow pinpointing molecules that might underlie the angiogenic plasticity of the microvasculature in skeletal muscle in response to exercise.

**HUMAN STUDIES - EXERCISE INDUCED CAPILLARY GROWTH AND GROWTH FACTORS**

Gustafsson, T.
Karolinska Institute, Stockholm, Sweden

Human skeletal muscle is an optimal tissue to study the molecular mechanisms in angiogenesis (neoangiogenesis from existing vessel) as well as other mechanisms underlying adaptive processes and signalling pathways in humans because it is accessible in amounts needed for analysis at the mRNA and protein levels. Newer methods, such as laser dissection of tissue sections provide ways to analyse the role of different types of cells. Physical exercise is also an ideal model for studying angiogenesis because it is one of the few conditions in which angiogenesis occurs in healthy humans and because it can be applied in a controlled manner (e.g., by varying intensity, duration and frequency) which makes it possible to study the effects of different metabolic and environmental conditions (e.g., oxygen, substrate and metabolic availability) on angiogenesis.

Recent studies have revealed that the suggested major angiogenic growth factors VEGF-A and angiopoietins systems are regulated in human skeletal exposed to exercise and numerous stimuli have been demonstrated to participate in these processes. In addition to angiogenesis, where vessels form through sprouting of resident endothelial cells neovascularization has recently been established to occur from circulating bone marrow-derived endothelial progenitor cells (EPCs), which differentiate into ECs EPC number in plasma increases in response to physical activity, but it is largely unknown whether they contribute to vessel formation in the remodelling skeletal muscle in human.

Future studies in humans are needed to integrate the growing basic knowledge from animal studies regarding various factors in the neovascularization processes and their interaction in human exercising muscle.

**Invited symposia (IS)**

**IS-PM02 GSK Symposium: Nutrition for running**

**ENERGY BALANCE AND BODY COMPOSITION OF ELITE ENDURANCE RUNNERS: A HUNTER-GATHERER PHENOTYPe**

Pitsiladis, Y.
University of Glasgow, United Kingdom

Given the fact that east African endurance athletes dominate global competition, it is reasonable to consider their training habits and lifestyle as being close to optimal for athletic performance. An ad libitum and rather low intake of water (Fudge et al., 2008), low body mass (Mukeshi and Thairu, 1993; Christensen et al., 2002) and body-mass-cycling with a negative energy balance prior to competition (Onywera et al., 2004; Fudge et al., 2006) are typically found in these athletes. Although it is unclear what constitutes an optimal hydration strategy and/or loss in body mass prior to competition, the performance implications for the modern athlete of a low fluid intake and reduced body mass were very evident when Homa was chasing its prey on the savannah grasslands in central Africa. However, athletes and coaches should be cautious in deliberately trying to lose excess body mass; rather a sensible diet/hydration strategy and training that aims to optimise an adequate mix of metabolic fuel stores for racing and a body weight that enables a reduced oxygen cost of movement is paramount.

**GASTROINTESTINAL SYMPTOMS IN RUNNERS**

Jeukendrup, A.
University of Birmingham, United Kingdom

Gastrointestinal (GI) complaints are very common amongst endurance athletes, in particular runners. An estimated 30 to 50% of distance runners experience intestinal problems related to exercise. The most common complaints include eructation (belching), abdominal pain, nausea, gastroesophageal reflex (or heartburn), abdominal pains, abdominal cramping, increased flatulence, loose stool, diarrhea or even bloody diarrhea, and vomiting. The complaints are normally divided into two categories: symptoms of the upper intestinal tract or symptoms of the lower intestinal tract. Lower gastrointestinal symptoms are more often observed in women than in men. Individuals with pre-existing GI issues such as reflux, lactose intolerance or irritable bowel syndrome are more likely to get GI-symptoms during competition. At present, the causes of gastrointestinal symptoms are not completely understood. A limited number of laboratory studies has been performed and field studies have correlated the symptoms with nutritional intake and other factors. From these studies a number of potential causes and contributors have been identified and they can be divided into 3 categories: (1) physiological, (2) mechanical and (3) nutritional.

Physiological causes of GI-symptoms include reduced blood flow and increased anxiety. With exercise, blood flow is preferentially redirected to the working muscles and blood flow to the gut can be reduced by as much as 80%. This can compromise gut function and result in GI symptoms ranging from cramping to ischemic colitis. Anxiety has an effect on hormone secretion which in turn can affect gut motility, resulting in incomplete absorption and loose stool.
The mechanical causes of GI-problems are either impact-related or are related to posture. GI bleeding is common amongst runners. This is thought to be a result of the repetitive high-impact mechanics of running and subsequent damage to the intestinal lining. This repetitive gastric jostling is also thought to contribute to lower GI symptoms such as flatulence, diarrhea and urgency. Estimates of the incidence of occult blood after a race range from 8% to 85% mostly because of the wide range of race distances in various studies. Finally nutrition can have a strong influence on GI distress. Fiber, fat, protein, and fructose have all been associated with a greater risk to develop GI-symptoms. Dehydration, possibly as a result of inadequate fluid intake, may also exacerbate the symptoms. Beverages with high carbohydrate concentrations and high osmolalities (greater than 500 mOsm/L) were also associated with more complaints. Although some risk factors have been identified it is still unclear why some individuals seem to be more prone to develop GI-problems than others. To minimize GI symptoms, all known risk factors must be taken into account, in preparation for competition.

NUTRITION AND THE FEMALE RUNNER
Wallis, G.
GlaxoSmithKline, United Kingdom
Considerable research has been directed towards developing nutritional strategies to optimise athletic performance. Traditionally, this is performed using athletic men as the study participants with findings and implications simply extrapolated to women athletes. An increasing number of studies are investigating the metabolic and ergogenic responses to nutritional interventions in athletic women. Although still in a state of relative infancy, these studies provide provisional insight into aspects of sports nutrition that could require tailoring based on the sex of the athlete.

IS-SH03 Technology and performance in sport: historical perspectives

THE CHANGING TECHNIQUES, BODIES, AND IMAGES IN SKI JUMPING
Pfister, G.
University of Copenhagen, Denmark
Ski jumping spread as a modern sport at the turn of the 19th to the 20th century from Scandinavia to whole Europe. The development of the equipment, technique but also of the jump resulted in increasing performances and large and larger jumping ranges. The ski jumpers were glorified as heroes and as men who presented and enacted strength, competence and daredevily. Ski jumping was and is one of the few sports where not only the quantitative performance but also the right posture is evaluated. This gave the experts the power of definition about the proper style of jumping.

In the 1990s, the technique of jumping changed to the so called V-style where the tips of the skis are spread and form a V. This style was at first punished by the judges but was adopted soon by all jumpers. This new style advantages light athletes and in the following time the ski jumpers became thin and thinner. On the one hand, the skinny men in their wide overalls and their tendency to get anorexic and depressed caused doubts about their masculinity. On the other hand, this new boyish image of the athletes met the taste of young girls. Thousands of girls streamed to the ski jumping events, wrote love letters to their favourites, founded fan clubs and opened web pages with stories and images, also erotic pictures of the successful German athletes Sven Hannawald or Martin Schmitt.

Based on the concept of sportification and a constructivist approach to gender, I will analyse the changes and the re-productions of bodies, images and masculinities in and through ski jumping. As examples I will use tow of the most successfull ski jumpers in the last decades: Martin Schmitt and Sven Hannawald.

My sources are skiing journals, popular literature and web pages. In addition I analysed all articles about the two athletes mentioned above in the magazine Der Spiegel and in two German news papers BILD and Welt.

POLE LEAPING THROUGH THE AGES: HOW HIGH, FAR OR LOW CAN YOU GO?
Renson, R.
Faculty of Kinesiology & Rehabilitation Sciences, K.U.Leuven, Belgium
Throughout time there have been three kinds of pole leaping. In Ancient Greece and Etruria pole vaulting was used to mount bareback horses. Pole vaulters sometimes appeared in Roman arenas and used their skills to escape from wild animals. Goya still observed a bullfighter leaping over a bull in the ring of Madrid around 1815-16. Medieval and later paintings and etchings, a.o. by Pieter Bruegel and Adriaen van de Venne, depict pole vaulters, who use their lenn poles to leap over ditches or other obstacles. When Johann J.F. Guttmuths ‘reinvented’ school gymnastics in Germany at the end of the 18th century, pole vaulting for height and for distance figured on his physical education curriculum. Pole vaulting for height has been on the Olympic program since the first Games of Athens 1896. In the 1930ies Olympic pole vaulting was contested by the gymnasts, who claimed it as one of their disciplines. Pole vaulting made a big leap upwards when fibre glass poles were introduced from 1964 onwards at the Rome Olympics.

Pole vaulting for distance (over a river) is still a popular traditional sport in the Dutch province of Friesia, where it called ‘fierljeppen’. The third variant is pole leaping in the depth, which is today still practised on the Canary Islands, where it known as ‘salto del pastor’. The question why only pole vaulting for heigt became a global sport and not the two other forms, will be discussed in the context of the modernisation concept.

THE EXPLORATION AND CONQUEST OF EVEREST: SCIENCE, TECHNOLOGY AND PERFORMANCE
Vanreusel, B.
K.U.Leuven, Belgium
The first ascent of Mount Everest in 1953 is considered as a benchmark in human performance. This paper addresses the impact of science and technology on this performance. The original report ‘The ascent of Everest’ by John Hunt (1953) is analysed as the primary
source. It is argued that the first successful ascent of Everest was the result of knowledge from geography, physiology, kinesantropometry and military technology. Later similar performances rather capitalized on exercise science and nutrition as dominant factors of success. The report of the first ascent of Everest will be interpreted by the opposing concepts of militarism versus modern sport and of technological determinism versus technological constructivism. It is argued that the first ascent of Everest has lost its technoscientific meaning and was transformed into an icon of modern sport.

OP-HF02 Health and Fitness 2

THE RELATIONSHIP BETWEEN FUNDAMENTAL MOVEMENT SKILLS AND PERCENT TOTAL BODY FAT IN 9-10 YEAR OLD CHILDREN

Foweather, L., McWhannell, N., Henaghan, J., Graves, L., Stratton, G.
Liverpool John Moores University, United Kingdom

OBJECTIVE: Overweight and obese children participate in less physical activity than non-overweight children (Trost et al., 2001), and this may be partly explained by differences in fundamental movement skill (FMS) proficiency. This study sought to examine whether percent body fat was associated with such skills.

METHODS: 158 children (Age Mean: 9.66, SD 0.32) were recruited from local primary schools. Eight skills were assessed using video analysis and process-orientated measures. Percent total body fat was determined by means of dual-energy x-ray absorptiometry (DEXA). The number of skill components successfully demonstrated for each skill was summed to create an overall FMS index score. Multiple linear regression and partial correlations were used to determine how much of the variance in FMS was explained by percent body fat, controlling for gender differences.

RESULTS: Percent body fat explained 6.5% of the variance in the FMS index score (p < 0.01). Specifically, a 1 unit (%) increase in body fat is associated with a 0.291 unit decrease in FMS index (95% CI: -0.43 to -0.147). When the skills were divided into locomotor and object-control subscales, percent body fat was only associated with locomotor skills (p < 0.01), accounting for 23.4% of the total variance. Explicitly, a 1 unit (%) increase in body fat is associated with a 0.257 unit decrease in locomotor score (95% CI: -0.33 to -0.18).

DISCUSSION: Using DEXA to calculate percent body fat, this study confirms the findings of previous studies that have used less robust methods of determining overweight and obesity (Okely et al., 2004, Southall et al., 2005). Proficiency in these 8 fundamental movement skills is associated with percent body fat. However, increased body fat is negatively associated with the performance of locomotor skills, rather than object-control skills.

CONCLUSION: Interventions seeking to increase fundamental movement skill proficiency in overweight or obese children should target locomotor skills. Such improvements may also positively impact on perceived competence, weight management and physical activity participation.

TARGET GROUP SPECIFIC APPLICABILITY OF CARDIORESPIRATORY FITNESS PREDICTION BY BIO-IMPEDANCE ANALYSIS

Thiel, C., Vogt, L., Banzer, W.
J.W. Goethe University of Frankfurt, Germany

PURPOSE
Determination of aerobic fitness status is crucial for the evaluation of health-enhancing physical activity (HEPA) interventions in different target groups. However, especially in elderly, inactive or chronically ill, the applicability of direct tests to full exertion seems questionable. Besides health, motivational and economic reasons, adverse attitudes towards physical activity might be fostered. The current cross-sectional study evaluated the feasibility of an established test-free aerobic capacity prediction method based on bio-impedance data collection in three characteristic cohorts who are in special need of HEPA.

METHODS
In 18 overweight (BMI>25kg/m²) and 18 inactive (<1h vigorous PA/week) healthy adults, as well as 18 patients with histologically confirmed cancer diagnosis, bio impedance analysis (IBIA 101/S, Data input, Germany, 50 Khz sinusoidal current) was performed using adhesive electrodes at hands and feet after 10 minutes of supine rest. Based on this measurement, aerobic capacity was indirectly estimated using the regression equation involving impedance index, physical activity rating and gender by Stahn et al. 2006. For comparison in all subjects, VO2peak (Viasys Oxyon mobile spirometer) was additionally determined directly during a performance-adjusted standardised graded exercise protocol.

RESULTS
VO2peak [ml*kg-1*min-1] measured by spiroergometry was 40.7±7.7 in overweight, 40.3±9.0 in inactive subjects and 24.6±7.1 in cancer patients. The IBIA based regression algorithm underestimated VO2 in these groups by an average 47±14%, 45±19% and 13±34%, respectively.

CONCLUSION
When applying the IBIA-based Stahn regression equation in overweight, inactive and chronically ill subjects, there is a potential VO2 underestimation on a group level as well as an individual misclassification in accordance to cohort characteristics. Prediction accuracy was lower with increasing VO2. However, impedance data by itself accounted for 65, 69 and 51% variance in VO2peak in these groups. Therefore, further studies for refinement of the IBIA approach by establishment of target group- specific regression equations and their cross-validation seem warranted.

EFFECTS OF AN ACCUMULATED BRISK WALKING INTERVENTION ON BODY COMPOSITION IN CHILDREN AGED 5-11 YEARS OLD

University of East London, United Kingdom

It seems that increased physical activity in childhood can affect an individual’s energy balance, and thus storage of excess adipose tissue. Surprisingly though there are a limited number of interventions performed within schools, especially using brisk walking, as well as the nation of accumulated physical activity. The purpose of this study was to identify whether an accumulated brisk walking programme within a primary school setting is effective in increasing energy expenditure and reducing body fat in 5-11 year old children.

152 participants took part in this intervention study, using both a walking (W) and control (C) group. W took part in the accumulated brisk walking programme during school time, which involved walking at a brisk intensity around the school grounds for 15 minutes in the morning and afternoon, at least 3 times a week. This represented an additional 90 minutes of walking week-1, during the 15-week intervention period. The distance and heart rate recorded during each brisk walk by a sample of W participants was 1437 ± 7.6m and 135.2 ± 9.6 beat min⁻¹, respectively (mean ± SD). C took part in normal school lessons during the walking sessions. Pre- and post-intervention measures of all the physiological variables were taken immediately prior to, and at the end of the 15-week period in both groups. Body fatness was measured using the BodPod Self-Test Life Measurements Inc, Concord, CAL. Additionally, skinfold thickness measures (Harpenden Skinfold Calipers, British Indicators Ltd, Luton, England) were recorded. Data was analysed using SPSS v13.0, with both parametric and non-parametric differences tests. Significance accepted at p<0.05.

EFFECTS OF AN ACCUMULATED BRISK WALKING INTERVENTION ON BODY COMPOSITION IN CHILDREN AGED 5-11 YEARS OLD

The principal finding of this study was that regular accumulated bouts of walking reduced body fatness (%) and fat mass (kg) in 5-11 year old children, whereas such changes were not observed in controls. The additional brisk walking increased the estimated energy expenditure by >240 kcal. It seems that this type of short-bout regular brisk walking, within the school day, has the potential to create a mild negative energy balance in primary school children, and thereby, could help to prevent obesity in young children.

THE RATING OF PERCEIVED EXERTION DURING COMPETITIVE RUNNING SCALES WITH TIME

Faulkner, J., Parfitt, G., Eston, R.
University of Exeter, United Kingdom

Recent research suggests that a scalar linear relationship exists between the ratings of perceived exertion and the duration of exercise during constant load exercise tasks on a cycle ergometer (Noakes, 2004, Eston et al., 2007). This was first suggested by Noakes (2004) during carbohydrate-depleted and carbohydrate-replete conditions, and by Eston et al. (2007) who observed the response following an antecedent fatiguing activity. It has also been suggested that the perception of exertion has scalar properties during closed loop cycling time-trials of either 2.5, 5 or 10 km (Joseph et al., 2008).

The purpose of this study was to assess whether the scalar internal timing mechanism of perceived exertion was evident during competitive running, and whether the distance, course elevation and the participants’ pacing strategy (running velocity) altered the perceptual response. After completing a graded exercise test to exhaustion on a motorised treadmill, nine men and women competed in a 7 mile road race (7-MR) and a half marathon (GWR, 13.1 miles), approximately one and two weeks later, respectively. The RPE, heart rate and split mile time were recorded throughout the duration of the races. The RPE was regressed against time and a ‘time’ to complete the 7-MR and GWR. As expected, the rate of increase in RPE was greatest in the 7-MR [F (1, 7) = 556.83, P < 0.001] although there were no differences when expressed against %time [F (1, 7) = 4.43, P > .05]. Although the RPE at the completion of the first mile of the GWR (10.8 ± 0.7) was significantly lower than the 7-MR [11.9 ± 0.6] (P < .01), similar RPE values were reported at the completion of the races [18.4 ± 0.5 & 18.9 ± 0.6, respectively, P > .05], despite significant differences in the course elevation, heart rate response, running velocity and pacing strategy adopted by participants during the races (P < .05). The study provides further evidence that the ratings of perceived exertion have scalar linear time-based properties. The study has also demonstrated that during competitive distance running the perceptual response may be dissociated from the underlying physiological or physical mechanisms associated with performance.

PHYSICAL ACTIVITY OR FITNESS: WHAT'S THE BEST PREDICTOR OF BONE MINERALIZATION AND WIDTH?

Faculty of Human Movement, Technical University of Lisbon, Portugal

The purpose of this study was to analyse the impact of physical activity (PA) and fitness on bone mineralization and width in prepubertal children. Methods: Participants were 53 girls (chronological age, 8.5±0.4 yrs; bone age 8.5±1.2 yrs; height,132.0±0.05 cm; weight, 29.2±5.9 kg) and 64 boys (chronological age, 8.6±0.4 yrs; bone age, 8.9±1.1 yrs; height,133.0±0.06 cm; weight, 32.3±7.4 kg). Evaluation of body weight, total lean and fat mass, bone mineral content (BMC) and area of total body, lumbar spine (L1-L4), femoral neck, and 33% radius were performed with DXA. PA was assessed with a uni-axial accelerometer. Aerobic capacity was evaluated by the PACER test according the manual of Fitnessgram 6.0. Muscle capacity was measured in lower limbs by a long stretch-shortening cycle with a counter movement jump and in upper limbs by a handgrip strength test. Maturation level was determined by the TW3 method (Tanner et al., 2001). Calcium intake was calculated from a semi-quantitative food frequency questionnaire assessing regular intake of a wide set of nutrients.
LACTATE RESPONSE TO CIRCUIT WEIGHT TRAINING: COULD IT BE RELATED WITH THE ACE I/D POLYMORPHISM?

Cuperio, R., Gonzalez-Lamuño, D., Amigo, T., Alvarez, M., Morencos, E., Peinado, A. B., Díaz, V., Benito, P. J.
(1) Faculty of Physical Activity and Sport Sciences, (2) Faculty of Medicine, Spain

INTRODUCTION
Lactate response to resistance training has only been studied in isolated exercises without comparing same protocols at different intensities. Individual variation in the cardiovascular response to the exercise due to genetic factors, such as the angiotensin-converting enzyme (ACE) gene polymorphism, are determinant with several fitness parameters and physical performance. However, only several studies without conclusive results have investigate the role of the ACE insertion/deletion (I/D) polymorphisms with lactate metabolism. OBJECTIVE: To describe lactate response to a circuit weight training on different intensities in relation with the ACE insertion/deletion (I/D) polymorphisms.

METHODS
10 male volunteers (mean ± standard deviation, age 24±1.8 years, height 178.2±5.4 cm, weight 78.2±7.1 kg) performed a circuit of 8 exercises at 6 different intensities (from 30% to 80% of 15RM) in 6 non-consecutive days. Capillary blood samples were analyzed at the end of each circuit, using the YSI 1500 STARK Lactate Analyzer. The I/D polymorphism of ACE gene was determined by polymerase chain reaction. Subjects were divided in 2 groups: I (II homozygotes and ID heterozygotes) and D (DD homozygotes).

RESULTS
Lactate concentration was significantly correlated with the circuit intensity (Spearman correlation=0.815, p=0.01). Mann-Whitney test showed significant differences between I group and D group (p=0.041) in maximal blood lactate during the strength circuit training, having lower concentration the I group. Percentage of genotypes: DD=70%, ID=20% and II=10%.

DISCUSSION AND CONCLUSIONS
Our results show that the increased energy requirement due to the increased intensity induces an elevated lactacid metabolism. Thus, the needed energy to increase resistance training intensity is not only due, as previously described, to a higher oxygen consumption, but also to an increased anaerobic metabolism. Furthermore, we found that individuals in I group reached lower lactate levels in strength training. These low levels might be caused by a worse oxygen delivery due to an impaired vasodilation in the ACE DD homozygotes. We conclude that lactate response to circuit weight training is very correlated with the intensity of this training, and that individuals in I group reached lower lactate levels in strength training.

TWO-STAGE FINE-MAPPING OF A LINKAGE PEAK FOR KNEE STRENGTH ON CHROMOSOME 12

Windelinckx, A., De Mars, G., Huygens, W., Peeters, M., Beunen, G., Aerssens, J., Vlietinck, R., Wijmenga, C., Lambrechts, D., Thomis, M.
Faculty of Kinesiology and Sports Sciences, Belgium

Myostatin (Growth and differentiation factor 8, GDF8) is known to be a key negative regulator of skeletal muscle mass. Despite its remarkable influence on skeletal muscle mass in animals, studies of human genetic variation in the myostatin gene have shown little association with muscle phenotypes, except for a rare missplicing change in IVS1:G378A. To clarify the inconclusive role of myostatin and other key proteins of the myostatin pathway, our research group conducted linkage analyses on young male Caucasian siblings from the Leuven Genes for Muscular Strength study (LGfMS). Microsatellite marker-based linkage analyses revealed that the region harbouring cyclin-dependent kinase (CDK2; 12q12-14; LOD 3.4; P = 0.0004) showed significant linkage to knee muscle strength. However, it is not possible to exclude that genes other than the original myostatin pathway candidate genes cause the linkage findings. Therefore a two-stage fine-mapping approach was conducted on the 1-LOD confidence interval of the linkage peak.
In stage 1, 209 polymorphisms were selected using an empirical two-step gene-centred fine-mapping strategy in which candidate genes are prioritized using a bioinformatics approach and the top genes are chosen for further SNP selection with a linkage disequilibrium based method. These SNPs were genotyped in 500 male Caucasian siblings from the LGMS study using an Illumina Bead Array platform. Combined linkage and association analyses and family based association tests identified 6 genes including activin receptor 1 beta (ACVR1B) and inhibin beta C (INHBC). Inhibins and activins belong to the TGF beta superfamily - as does myostatin - and signal through a combination of type II and type I receptors, of which ACVR1B is one. Therefore ACVR1B and INHBC make strong candidates for follow-up. In stage 2, an additional 27 SNPs, likely to have functional consequences (i.e. exonic SNPs, SNPs located on intron/exon boundaries and SNPs in [putative] transcription factor binding sites or in highly conserved regions) were successfully genotyped using Sequenom iPLEX Gold technology in 510 individuals, partially overlapping stage 1 individuals. Family based association analyses for SNPs in ACVR1B on isometric knee strength and concentric torque of the knee extensors and flexors at 60°/s revealed empirical p-values ranging from 0.003 to 0.04 for a polymorphism located in a miRNA binding site and from 0.003 to 0.07 for a SNP located in a conserved region. For INHBC none of the additional SNPs was significantly associated with muscle strength.

Further research will be necessary to evaluate whether the associated genotypic variations in these candidate genes with muscle strength can be explained by an associated variation in mRNA expression or protein level and whether these associations can be replicated in independent samples.

PROTEOMIC IDENTIFICATION OF SEX-SPECIFIC DIFFERENCES IN MUSCLE HEAT SHOCK PROTEIN EXPRESSION IN RESPONSE TO INTERVAL TRAINING

Holloway, K., Goldspink, D., Cable, N., Burniston, J.
Liverpool John Moores University, United Kingdom

Background
Sex-specific differences in muscle metabolism have been reported (Tarnopolsky et al., 1990), but the potentially different responses of muscle to interval training have not been investigated. To question this, we used proteomics techniques that provide a broad assessment of muscle proteins. This approach has not previously been used to study the adaptation of muscle to exercise training and can provide novel molecular information.

Methods
Five health-screened recreationally active men (mean±SE; age 21±3 years, body mass 71±9 kg) and 5 women (age 20±2 years, body mass 55±6 kg) completed the training programme after giving their informed consent to the ethically approved procedures. Maximum oxygen uptake was measured and each subject completed a 6 weeks treadmill running programme, involving 3 sessions per week, utilising six 1-minute bouts at 100% maximal oxygen uptake interspersed with 4 minutes of 50% maximal oxygen uptake. The vastus lateralis was biopsied at standardised times before, and after, the training intervention and proteins resolved using isoelectric focusing (pH 3-10) and gel electrophoresis. Gels were stained with colloidal Coomassie blue and analysed using proteome profiling software. Spots of interest were digested with trypsin and analysed using mass spectrometry. Gene products were identified by searching peptide ion and fragment ion mass spectra against the Swiss-Prot database using Mascot (www.matrixscience.com).

Results
Six weeks of interval training increased average maximum oxygen uptake by 8% in men and 7% in women (P=0.001), with corresponding increases in arterio-venous difference (4% in men, 10% in women; P=0.005). In males, the expression of 7 gene products was significantly different after interval training. Expression of muscle creatine kinase increased 50% (P=0.022), fast troponin T by 60% (P=0.032) and myosin regulatory light chain 2v by 24% (P=0.015). In contrast, slow troponin T decreased 115% (P=0.008) and myosin essential light chain 1s by 40% (P=0.049), suggesting a shift toward a faster contracting phenotype in men. In women, only the expression of heat shock protein 27 was significantly (P=0.032) increased (33%) after interval training, whereas in men significant increases in the expression of heat shock proteins 70 (8%, P=0.012) and 20 (31%, P=0.009) were detected.

Conclusions
Proteomic analysis can provide mechanistic evidence of sex-specific responses to exercise. Skeletal muscle adaptation to a standardised regimen of interval training was greater in men than in women. Consistent with previous findings in rats (Paroo et al., 2002), this training intervention elevated the expression of heat shock protein 70 in vastus lateralis of males, but not females. Sex-specific differences in the response of the small heat shock proteins 20 and 27 were also discovered.

FAK TRANSMITS MECHANICAL STRESS TOWARDS INCREASED PROTEIN SYNTHESIS IN SKELETAL MUSCLE

Klossner, S., Durieux, AC., Freyssenet, D., Hoppeler, H., Flueck, M.
University of Bern, Switzerland

Mechanical load leads to increased muscle mass and a gain in muscle strength. Classical cell biology experiments led to the identification of kinases that activate protein synthesis and thus trigger muscle growth. However, the molecular link between the mechanical (extracellular) stress and the chemical (intracellular) signaling towards protein synthesis has not been identified so far. We examined the possible functional coupling between the activation of a key player of protein synthesis in striated muscle, the 70kDa ribosomal protein S6 (extracellular) stress and the chemical (intracellular) signaling towards protein synthesis has not be en identified so far. We examined the
reloading [1.59-fold]. This FAK activation preceded the phosphorylation of p70S6K at activation sites Ser411 and Thr421/Ser424 after 6 hours of reloading and the subsequent 3.8-fold (p<0.05) enhancement of p70S6K phosphotransfer activity 24 hours after reloading. In ongoing experiments we aim to verify these results in the tenotomy-model, in which we expose a much higher mechanical stress to the muscle. Taken together, our data provide evidence for the involvement of the mechano-sensory FAK in transmitting the mechanical signal and promoting protein synthesis.

THE ROLE OF SIRTUINS IN AGED EXERCISE TRAINED AND IGF-1 TREATED RAT SKELETAL MUSCLE

Semmelweis University, Hungary

Sir2, an NAD+-dependent protein deacetylase, extends the lifespan in diverse species from yeast to flies. Sir2 has seven mammalian homologs; SIRT1-7, which affect aging and metabolism. Conservation of sirtuin regulation of the insulin-like growth factor 1 (IGF-1) signaling pathway has been observed for Caenorhabditis elegans and mammals, indicating an ancient role for sirtuins in the modulation of organism adaptations to nutritional intake and metabolism.

We conducted a study in which, Wistar male rats (3 mo and 26 mo) were divided into six groups. The training protocol lasted for 6 weeks (5times/wk, 1h/day, reaching the intensity of 22m/min for young and 13m/min for old groups at the incline of 10% for both groups). In the last two weeks of the training program Alzet pump was inserted into the animals with and without IGF-1. The concentration of adminis-
tered IGF-1 was 5 µg/body weight kg/day. Gastrocnemius muscle was used in the present study.

The Western blot data revealed that SIRT1 content did not change as a result of aging. On the other hand, exercise appears to decrease the protein level while IGF-1 administration increases the content of SIRT1. H3K9 histone acetylation changed with different pattern in young and old animals for exercise training and IGF-1 supplementation. SIRT1 acts as suppressor for UCP3 gene, UCP3 is a mitochondrial membrane transporter which also significantly effects the production of free radicals. Accordingly to this, we have found that increased SIRT1 content was associated with decreased UCP3 level especially in exercise trained rats. SIRT1 believed to influence the DNA repair, and interestingly enough, the activity of 8-oxoguanine glycosylase in the nucleus changed with similar pattern as SIRT1. Although, the concentration of nuclear 8-hydroxy-2-deoxyguanosine was not significantly altered by aging or exercise. The level of carbonyl groups of the protein level while IGF-1 administration increases the content of SIRT1. H3K9 histone acetylation changed with different pattern in young and old animals for exercise training and IGF-1 supplementation. SIRT1 acts as suppressor for UCP3 gene, UCP3 is a mitochondrial membrane transporter which also significantly effects the production of free radicals.

In the present study we have some novel observations: Exercise and aging alter the SIRT concentration in the skeletal muscle and this concentration of nuclear 8-hydroxy-2-deoxyguanosine was not significantly altered by aging or exercise. The level of carbonyl groups of the protein level while IGF-1 administration increases the content of SIRT1. SEASONAL EVALUATION OF CHANGES IN MUCOSAL IMMUNITY AND UPPER RESPIRATORY ILLNESS AMONGST ELITE RUGBY UNION PLAYERS

Cunniffe, B., Jones, K., Griffiths, H., Proctor, W., Baker, J., Davies, B.
University of Glamorgan and Wales Rugby Union, United Kingdom

Previous studies have shown that intense exercise results in suppression of host immunity. This may predispose athletes to an increased risk of developing upper respiratory illnesses (URI's). Few studies have investigated changes in mucosal immunity and URI development within multi-stressor team environments over prolonged periods (Fahlman and Engels, 2005). OBJECTIVES: To assess the effects of exercise stress on markers of mucosal immunity and URI incidence in elite rugby union players.

METHODS: Thirty players [mean ± SD: age 26.4 ± 2.5 yr, height 186.5 ± 8.7 cm, weight 101.1 ± 15.2 kg, VO2peak 52.1 ± 6.2 ml kg⁻¹ min⁻¹] agreed to participate in the study passed by the ethical committee of the University of Glamorgan. Timed, unstimulated morning saliva samples were taken from players (lasted) at pre-selected time points over the course of a competitive playing season (11 months). Samples were taken after a minimum of 48-h rest from the previous game or intense exercise and analysed via ELISA for possible changes in salivary cortisol, immunoglobulin A (s-IgA) and lysozyme (s-Lys) concentration and secretion rate. Weekly self-reported player illness data was obtained using an 'internet' based data logging system. Additional data recorded by affiliated medical staff. Daily records of training load, type, duration and perceived intensity were obtained using the same system.

RESULTS: Players reported on average, 4 URI episodes (min = 0; max = 8) over the 46 wk study period. Average duration of reported URI's lasted 4.5 days (min = 2; max = 33). Peaks in URI's occurred during the months December and March were preceded by increases in training intensity. Values for s-Lys and salivary cortisol concentration were lowest and highest during this time period. The increase in URI incidence during December was also associated with a significant (P < 0.05) decrease in s-IgA concentration and secretion rate. Recorded number of URI episodes differed for player position (mean ± SD): 3.4 ± 2.1 vs 4.3 ± 2.03 for forwards and backs respectively. Backs also displayed lower mean resting s-IgA and s-Lys concentrations and secretion rates when compared to forwards across the study period.

CONCLUSIONS: Regular monitoring of s-IgA and s-Lys may be useful in the assessment of both exercise stress and URI risk status within elite rugby union. A combination of alterations in training intensity and seasonal influence are likely contributors to observed peaks in URI incidence. Possible stress induced changes in cortisol release may contribute to reductions in resting s-IgA and s-Lys concentrations over prolonged periods. A critical threshold for s-IgA may exist in predisposing elite rugby union players to increased URI incidence.

EXERCISE INDUCES APOPTOSIS OF LYMPHOCYTE SUBPOPULATIONS IN LYMPHOID ORGANS

Krueger, K., Tunca, E., Mooren, F.C.
Institute of Sports Sciences, Justus-Liebig-University, Giessen, Germany

Intensive exercise affects lymphocyte counts in lymphoid and non-lymphoid organs via different mechanisms like redistribution as well as proliferation and apoptosis. The role of apoptosis is currently under focus of research since intensive exercise is well known to increase several apoptosis-inducing factors including reactive oxygen species, Fas receptor, TNF-α, glucocorticoids, and intracellular calcium. Purpose: To investigate the effect of intensive exercise on apoptosis of lymphocyte subpopulations in several lymphoid organs and to study the kinetics of these alterations.

Methods: Eight week old male CD1-mice were assigned either to an exercise group or to a control group. In the exercise group mice performed an acute treadmill exercise at 80% VO2max until exhaustion, while controls were exposed to treadmill noise without running. Mice were sacrificed immediately, 3h, 24h or 48h after exercise. Spleen, lung, Peyer’s patches, inguinal lymph nodes and bone marrow were excised and blood samples were taken. Lymphocytes were isolated and stained using PE-conjugated monoclonal antibodies against CD3, CD4 and CD8. Detection of apoptotic cells was performed by flow cytometry using FITC-conjugated annexin V.

Results: In the spleen we observed an increased percentage of apoptotic CD3+, CD4+ and CD8+ cells immediately and 3h after exercise. Rate of apoptotic CD3+ and CD4+ cells were still increased 24h after exercise and decreased 48h after exercise. In blood, apoptosis of CD3+ and CD4+ cells increased immediately and 3h after exercise and reached baseline values 24h after exercise. In Peyer’s patches, apoptosis of CD3+ increased immediately and 3h after exercise and was still enhanced 24h after exercise. In contrast, in lung, lymph nodes and bone marrow we observed a delayed increase in apoptosis. In lung and bone marrow apoptosis of CD3+, CD4+ and CD8+ increased 24h after exercise and reached baseline levels 48h after exercise. Furthermore, in lymph nodes percentage of CD3+ and CD4+ increased 24h after exercise and reached baseline levels 48h after exercise.

Conclusion: An acute bout of intensive treadmill running increased lymphocyte apoptosis in several lymphoid organs, but with different kinetics. We speculate that exercise induced apoptosis in different organs might have a regulatory function to remove activated cells mobilized during exercise. It remains to be shown whether different rates of apoptosis in the lymphoid compartments are related to different concentrations of apoptosis-inducing factors.

IDENTIFICATION OF LEUKOCYTES IN HUMAN SKELETAL MUSCLE

Egner, I., Paulsen, G., Koskinen, S., Raastad, T.
Norwegian School of Sport Science, Norway

Accumulation of neutrophils in muscles after exercise-induced muscle damage has not been convincingly demonstrated. Results from immunohistochemistry indicate that infiltration is more evident in animal than human studies. The discrepancy may be due to the antibodies used to detect neutrophils [1]. The aim of this study was to identify different leukocyte antigens with a panel of frequently used antibodies in muscle exposed to unaccustomed eccentric exercise in humans. Secondly, we evaluated the specificity of these antibodies to identify neutrophils and macrophages.
Thirty-three subjects (26 ± 5 yr, mean ±SD) performed a bout of maximal eccentric exercise. Biopsies were taken 0.5, 1, 3.5, 8, 24, 48, 96 and 168 hrs after exercise (3-4 biopsies per subject). Anti-CD11b, CD16, CD66b, CD68, MPO and elastase, were used to detect leukocytes on cross-sections from both exercised and control muscle. A positive cell was defined as overlap of antibody and DAPI staining. Double labelling and labelling on adjacent cross-sections with different antibodies were performed to examine the reactivity of the different antibodies to neutrophils and monocytes/macrophages in muscle samples and on blood smears. Eccentric exercise resulted in reduced force-generating capacity after exercise (~50%) and prolonged recovery (> one week). The CD11b, CD66b and elastase antibodies stained a low number of cells at all time points. CD66b stained fewer cells than the CD11b antibody. The CD11b+, CD66b+ and elastase+ cells were found primarily in the perimysium and near blood vessels. Both the CD11b+, CD66b+ and elastase+ cells had typically polymorphic nuclei, but the CD11b antibody showed also weak affinity for mononuclear cells, which appeared to be monocytes. CD68+ cells were more frequently observed in exercised muscle compared to control (p<0.05). Within 24 hrs CD68+ cells were distributed throughout the sections, especially within perimysium. At 48 hrs CD68+ cells where more often observed in the epimysium. Later, necrotic fibres contained large numbers of CD68+ cells. CD68+ cells appeared to be mononuclear cells. Staining with CD16 followed the same pattern as with CD66b, but stained 17% fewer cells. Double-staining confirmed that these antibodies recognized many of the same cells. Sections double labelled with both CD66b and MPO showed larger number of MPO+ cells compared to CD66b+ cells. Blood smears showed that CD66b+ cells were positive for MPO. Anti-MPO also stained cells that appeared to be monocytes. Double-staining with MPO and CD66b on blood smears showed that many of the CD66b+ cells were positive for MPO. The main leukocyte subtype that accumulated in muscle after damaging exercise was monocytes/macrophages (CD68+ cells). It seems like CD66b and elastase are good markers for neutrophils, whereas CD11b and especially CD16 and MPO are not specific to neutrophils in human skeletal muscle.

IMMUNOLOGICAL RESPONSES TO INCREASED DIETARY PROTEIN INTAKE DURING INTENSIFIED TRAINING IN CYCLISTS

Witard, O., Jackman, S., Kies, A., Bosch, J., Jeukendrup, A., Tipton, K.
University of Birmingham, United Kingdom

The present study investigated the impact of additional dietary protein intake on immune responses during overreaching. In a single-blinded, counter-balanced experimental design, eight trained cyclists (Wmax: 354±28W) completed two identical, three-wk trials, consisting of a normal (NOR) intensified (INT) and recovery (REC) training week. In the experimental trial, cyclists consumed a high protein (PRO) (3g protein/kgBM/d) diet during INT and REC. In the control (CON) trial, a eucaloric normal protein diet (1.5g protein/kgBM/d) was consumed. Exercise performance was assessed using a pre-loaded (120-min @ 50%Wmax 45-min time trial ITT) on the final day of each training week. Immunological and hormonal measurements were collected at baseline, following submaximal exercise (IT120), at immediate cessation of TT (T+45) and following one-h recovery (R+60). Total lymphocyte counts were determined using a couler haematology analyser. Extensive leukocyte and lymphocyte sub-population phenotyping was performed using multicolour flow cytometry. Conjugated monoclonal antibody combinations were used to stain peripheral blood for surface antigens common to cytotoxic T lymphocytes (CTLI), helper T lymphocytes (ITH), B lymphocytes and Natural Killer (NK) cells. A highly cytotoxic and tissue-infiltrating CTL subset, denoted terminally differentiated effector-memory cell (TDEM), was identified on the basis of differential expression of the surface markers CD27 and CD45RA. A Daily Analysis of Life Demands of Athletes questionnaire monitored psychological symptoms of overreaching. Following INT, a significant decrease (12±4% vs. NOR) in TT performance (P=.02) and increase in mood disturbance (P=.05) was observed, indicating a state of overreaching was induced. During NOR, a robust mobilisation of CTL was observed at T+45 +110±13% from baseline, but this response was blunted during INT (+80±15% from baseline) (P=.02). PRO normalised this blunted response following INT (+112±17% from baseline). During INT, mobilisation of highly cytotoxic TDEM cells were upregulated in PRO (16±1.72 cells/µl blood) compared to CON (109±37 cells/µl blood) at T+45 (P=.02). A delayed attenuation in mobilisation of NK cell number was observed at R+60 during REC (79±13 cells/µl blood) compared to NOR (114±6 cells/µl blood) (P=.05). Diet did not impact NK cell number. INT did not perturb circulating Th or B lymphocyte subsets. Absolute increases in plasma cortisol concentrations at T+45 observed during NOR (116±18ng/ml from baseline) were attenuated following INT (70±27ng/ml from baseline) (P=.04), however no effect of dietary protein was observed. In conclusion, these findings indicate that overreaching induced decrements in endurance performance and mood state may be accompanied by an imposited mobilisation of tissue-infiltrating cytotoxic T lymphocyte and NK cells. Increasing dietary protein intake may help normalise these blunted exercise-induced immune responses.

EFFECTS OF AGED AND YOUNG SERUM ON PRIMARARY HUMAN MUSCLE CELLS STUDIED IN CULTURE

George, T., Velloso, C., Harridge, S.
Kings College London, United Kingdom

Introduction:
Ageing is characterised by a loss of muscle mass (sarcopenia). The mechanisms contributing to this loss are not known. One theory is that sarcopenia results from an impaired response to contraction-induced injury. In rodent muscle, evidence suggests that changes in circulatory factors contribute to the regenerative decline by affecting satellite cells [1].

Aim:
The aim of this study was to assess the myogenicity of human satellite cells cultured in serum from young or old subjects. Myogenicity was defined as the % of cells expressing desmin (a muscle cell marker) in proliferating cultures, and was further assessed by determining the ability of cells to express myosin heavy chain (MHC) when cultured in conditions that promote cell differentiation and fusion.

Methods:
Needle biopsies were taken from the vastus lateralis muscle of women aged 23 and 65 years. Serum was obtained from 4 young (ages 23-36) and 4 elderly (ages 65-81) subjects. The tissue was digested with trypsin and the resulting cell supernatant was cultured in a humidified incubator at 37°C and 6% CO2 in skeletal muscle cell growth medium (Promocell, Germany) supplemented with 10% foetal calf serum (PSF). For desmin experiments, cells were plated at a density of 1250/well in 96 well dishes. After 24 hours medium was replaced with basal skeletal muscle medium supplemented with 15% human serum (H5) and fixed after 92 hours in 4% paraformaldehyde + 0.4% Triton. For MHC experiments cells were plated at a density of 5000 cells/well. The PSF was replaced with basal medium containing 2% H5 and fixed after 11 days. Immunocytochemistry was performed using mouse monoclonal

ANNUAL CONGRESS OF THE EUROPEAN COLLEGE OF SPORT SCIENCE

OP-PM02 Physiology 2 - Immunology

13TH ANNUAL CONGRESS OF THE EUROPEAN COLLEGE OF SPORT SCIENCE

48
antibodies against desmin (D33, Santa Cruz) or MHC (MF20, DSHB University of Iowa) and a rabbit anti-mouse secondary antibody conjugated to Alexa Fluor 488 (Invitrogen). The nuclei were counterstained with Hoechst 33258. Analysis was performed using a Zeiss Axiovert fluorescence microscope.

Results:

Cells from the elderly subject showed a tendency towards a higher % of desmin +ve cells when cultured in the young serum (YS, 31.2 +/- 3.4%, mean +/- sem) as compared to old serum (OS, 24.2 +/- 2.9%, p=0.063). In contrast, the age of serum had no effect on the cells from the young subject (61.6 +/- 1.4% in YS v 62.3 +/- 1.9% in OS). The age of serum also did not affect the differentiation of the cells derived from either the elderly [25.5 +/- 3.7 in YS v 25.8 +/- 5.3% in OS] or young subject [43.6 +/- 2.2 in YS v 41.5 +/- 1.8% in OS].

Conclusion:

The data suggest that cells derived from elderly but not young individuals may be sensitive to factors in the aged human circulation that affect myogenicity. These factors do not affect differentiation. This contrasts with data on mice (1) in which satellite cells from young animals showed reduced expression of muscle markers when cultured in old serum.

PERFORMANCE, IMMUNE STATUS AND MUSCLE DAMAGE DURING AN INTERNATIONAL FIELD HOCKEY TOURNAMENT

Sunderland, C., Stokes, K., Morris, J.
Nottingham Trent University; University of Bath; Loughborough University, United Kingdom

PURPOSE In major events such as the Olympics, elite field hockey players are required to compete in a series of matches, which sometimes occur on consecutive days, but are rarely separated by more than 1-2 days. However, little is known about performance during, and the physiological implications of, such demanding match schedules. Thus, the aim of the present study was to assess the impact of tournament play on performance and markers of immune status and muscle damage.

METHODS Sixteen male international field hockey players gave their informed consent to participate in the study. The mean (SD) age and mass of the players was 25.6 (2.5) years and 78.9 (7.2) kg, respectively. Data was collected during a 13 day period comprising: Days 1-4, training and match preparation; Days 5-13, 6 tournament (world ranking) matches. Fasted venepuncture blood samples were collected on days 1 and 13, with fasted capillary blood samples taken daily on all other days, except day 2. Plasma was analysed for creatine kinase (CK). Unstimulated saliva samples were collected, from day 2 through to 13 and analysed for IgA. A global positioning satellite system (GPS) was used during matches to assess heart rate, and the distances run at particular speeds ('walk', 0-4; 'slow jog', 4-7; 'jog', 7-11.0; 'run', 11-15.5; 'fast run', 15.5-20; 'sprint', >20 km/h) and intensities ('low', 0-7; 'moderate', 7-15.5; 'high', >15.5 km/h). GPS data is presented for 9 players who played in all matches and blood data for 15 players. Data were analysed using 1- and 2-way ANOVA with repeated measures. Statistical significance was accepted as P<0.05.

RESULTS Mean distance covered during the 6 matches increased during the tournament and was 6397 (1764), 6345 (1397), 6620 (1628), 6777 (1449), 7103 (1788) and 7051 (1255) m for matches 1 to 6, respectively (P<0.05). Despite covering over 7 km in match 6, the mean distance sprinted was lower than in matches 1, 3, 4 and 5 (match 1 to 6: 411 (131), 363 (211), 477 (132), 499 (158), 515 (271) and 394 (187) m; P<0.05). As the tournament progressed it appeared that the intermittent activity patterns during matches became less extreme as players spent more time 'jogging' and 'running' (both P<0.01) and less time sprinting and walking (P<0.05 and P<0.01 respectively). Players achieved lower mean speed and heart rate and spent less time in the 'high intensity' exercise zone in the second half of all matches (all P<0.01, 2nd vs 1st half, indicating fatigue over the course of each match. Salivary IgA was lowest on day 2 (174 (89) ug/ml; P=0.05) and CK increased the day after each match (P<0.01) reaching a peak of 513 (291) U/l following matches on 2 consecutive days (P<0.01).

CONCLUSION With repeated match exposure during tournament play, elite field hockey players exhibit altered intermittent activity patterns. Further work is required to determine whether these altered activity patterns are a consequence of fatigue during later matches.

ELECTRICAL AND MECHANICAL CHARACTERISTICS OF FINGER FLEXOR MUSCLES DURING ISOMETRIC CONTRACTIONS IN ELITE ROCK CLIMBERS

Esposito, F., Limonta, E., Cè, E., Orizio, C., Veicsteinas, A.
University of Milan, Italy

The typical rock climbing effort involves mainly isometric contractions of high or maximal intensity. Therefore, maximal isometric strength of the upper limb muscles is a critical factor in climbers’ performance. The aim of the present study was to determine, by means of surface EMG and mechanomyogram (MMG) combined approach, the differences between climbers and sedentary controls in finger flexors motor unit (MU) activation strategy. Our hypothesis is that several years of rock climbing induced structural and neural changes that can be detectable by EMG-MMG compared analysis. Eleven elite climbers and ten healthy controls volunteered for the study. Anthropometric characteristics and maximal voluntary contractions (MVC) for each subject were measured. Five levels of short isometric contractions at 20, 40, 60, 80 and 100% MVC were performed in a randomized order. During each contraction, EMG, MMG and force signals were recorded. EMG and MMG were analyzed in time and frequency domain, and the root mean square (RMS) and mean frequency (MF) were then calculated. Climbers showed significantly higher values of MVC and MMG per unit of muscle area. EMG RMS was statistically higher in climbers with respect to controls for the range of effort from 60% to 100% MVC. In climbers MMG RMS increased up to 80% MVC, while in controls it increased only up to 60% MVC. MMG MF was higher in climbers than in controls at all exercise intensities (p<0.05). EMG-MMG combined analysis revealed significant differences in MU activation strategy between the two investigated groups. In particular, climbers had a significantly higher maximum force, electrical activity and average firing rate, as revealed by MMG MF values. These results are compatible with a shift of climbers’ muscles toward faster MUs, namely type II MUs. Thus, the hypothesis that many years of sustained isometric contractions during climbing activities induced changes in climbers skeletal muscle at a morphological and neural level, is confirmed.
EFFECTS OF ISOMETRIC EXERCISE TRAINING INTENSITY UPON REDUCTIONS IN RESTING SYSTOLIC BLOOD PRESSURE

Wiles, J., Coleman, D., Swaine, I. 
Canterbury Christ Church University, United Kingdom

The purpose of this study was to compare the effects of two intensities of double-leg isometric exercise training upon resting blood pressure. 33 subjects with a mean age of 20.2 ± 3.6 yrs, body mass 75.6 ± 12.2 kg and stature 179.4 ± 7.6 cm (mean ± s), gave informed consent and were randomly allocated to either control (CON), high-intensity (HI) or low-intensity (LO) isometric exercise training for 8-weeks. The isometric training intensities were set at the proportion of peak EMG (%EMGpeak), which corresponded with either 95% (HI) or 75% (LO) of the peak heart rate (HRpeak) achieved during an incremental isometric exercise test to exhaustion. Each subject performed 4 bouts of exercise, with 2 minutes rest in between, on 3 occasions per week, by maintaining a target EMG value. Resting blood pressure was measured at the brachial artery, seated, using an automated oscillometric device, at baseline, 4-weeks and post-training (8-weeks). ANOVA revealed that resting systolic blood pressure fell significantly in both groups after 8 weeks of training (from 121.5 ± 4.6 to 116.3 ± 6.9 mmHg for HI; and from 118.0 ± 10.1 to 114.3 ± 8.6 mmHg for LO). However, the reduction was also evident at 4 weeks in the HI group, findings we would suggest that the mechanism for adaptations in resting blood pressure after isometric exercise training is dependent upon exercise intensity.

THE PRECISION WITH WHICH ISOMETRIC EXERCISE TRAINING CAN BE PERFORMED ACCORDING TO A GIVEN HEART RATE

Swaine, I., Coleman, D., Wiles, J. 
Canterbury Christ Church University, United Kingdom

Previously, it has been suggested that the relationship between heart rate (HR) and electromyography (EMG) during an incremental isometric exercise test can be used to achieve precise intensities of isometric exercise training. The purpose of this study was to assess the precision with which this could be done. 22 subjects with mean Age 20.5 ± 4.3 y, Statute 1.79 ± 0.08 m, Body Mass 77.4 ± 13.2 kg, performed a double-leg incremental isometric exercise test to exhaustion, and the linear relationship between HR and EMG was established. From this, isometric training was set at an intensity (EMG) which was predicted to elicit a group mean HR of either 89 or 101 b.min-1 (resting group mean HR of 66 b.min-1). Subsequently, HR was recorded during an 8-week double-leg isometric exercise training programme. The training sessions involved 4 × 2 minute bouts of double-leg isometric exercise, with 2 minutes rest in between, and they were performed, using an isokinetic dynamometer, on three occasions per week (totaling 192 minutes of exercise). Subjects attempted to maintain a 'target' EMG value which was selected so as to elicit a given HR (either 89 or 101 b.min-1). The isometric training resulted in a mean HR which differed from the predicted 89 b.min-1 by only 1.39 ± 1.96 b.min-1, and which did not differ at all from the predicted 101 b.min-1 (1.00 ± 2.55 b.min-1). These results show that, when using the linear relationship between HR and EMG, it is possible to prescribe isometric exercise training, at intensities which elicit given heart rates, with great precision. This might be useful when studying the physiological mechanisms underlying the effect of isometric exercise training upon resting blood pressure, because it allows the 'cardiovascular training stimulus' to be quantified.

MUSCLE FORCE VARIABILITY STRUCTURE DURING FATIGUE AND HYPERTHERMIA

Brazaitis, M., Skurvydas, A., Ratkevicius, A., Daniuseviciute, L. 
Lithuanian Academy of Physical Education, Lithuania

Thomas et al. [2006] showed that the neuromuscular impairment during hyperthermia is primarily due to a central failure to fully activate skeletal muscles as it occurs independently of muscle and skin temperature. Muscle force shows significant variations when volunteers try to maintain it constant during isometric contractions (Tracy et al. 2005). It is not quite clear how hyperthermia affects force variation during such exercise. It was therefore the purpose of this study to determine how hyperthermia influence muscle voluntary activation and force variations during 2-min maximal voluntary isometric contraction (MVC) of the quadriceps muscle. Nine volunteers [mean (SEM); 21.7 (0.8) years of age] performed a 2-min maximal voluntary contraction (MVC) after 45-min passive body heating in the water at 44 C (HT experiment) and without the heating (ICON experiment). The degree of central activation ratio (CAR) during sustained maximal knee extensions was assessed by superimposed electrical stimulation with a 250-ms test train of stimuli at 100 Hz (MT100Hz) to nervus quadriceps. To examine the time-dependent structure, the sample entropy (SampEn) of force output was calculated. After passive heating, muscle temperature increased from 36.7 (0.28) C to 39.6 (0.31) C (p < 0.001) and Tre from 37.3 (0.32) to 39.3 (0.31) C (p< 0.001)!. At the same time the body mass decreased by 0.93 (0.32) kg which corresponds with 1.17 (0.4) % of the total body mass. During the first 30 s of MVC torque decreased to a lower level in hyperthermia compared to the control experiment ([52.6 (2.3)% and 69.0 (2.3)% of the best MVC, respectively, p<0.001). During the remaining 1.5-min MVC torque decreased at a similar rate in both conditions. The ANOVA showed that coefficient of variation for torque (CV) increased (p<0.0001) with exercise duration and was consistently higher in hyperthermia compared to the control condition. Allready after ~3-s of exercise, CAR was lower in hyperthermia compared to the control condition (p<0.03). The difference between the experimental conditions increased by 30-s of exercise (p<0.001). Afterwards, however, CAR underwent only minor changes and the difference between the experimental conditions was maintained until the end of exercise. There was a significant decrease (p<0.001) in the SampEn during 2-min MVC independantly of the exercise conditions.

It is concluded that hyperthermia inhibits voluntary activation and increases force variations during MVC. However, muscle force regularity (complexity) decreases and its does not depend on hyperthermia.

FACTORS CONTRIBUTING TO THE INCREASE IN SPECIFIC FORCE OF THE QUADRICEPS FOLLOWING RESISTANCE TRAINING IN YOUNG MEN
Erskine, R., Tomlinson, D., Degens, H., Jones, D.
Institute for Biomedical Research into Human Movement and Health, United Kingdom

BACKGROUND: The maximal force a muscle can generate depends on the number of sarcomeres in parallel and thus its physiological cross sectional area (PCSA). However, the increase in muscle strength with training is widely reported to be greater than expected from the increase in these two. The aim of this present investigation was to systematically address potential problems such as may be caused by changes in voluntary activation and co-activation and changes in muscle architecture during maximum voluntary contraction (MVC). To our knowledge, this is the first study to investigate the effect of resistance training on specific tension taking into account the structural differences between the four quadriceps muscles. METHODS: Fourteen healthy male volunteers aged 21+-3 yrs performed unilateral leg-extension (4 sets of 10 repetitions at 80% 1RM), three times/wk for 9 weeks. Quadriceps tendon force (FT) was calculated by correcting maximum isometric torque obtained at the optimum knee angle for antagonist coactivation (estimated from electromyographic activity), voluntary agonist activation (using the interpolated twitch technique), patella tendon moment arm and the ratio of quadriceps tendon force to patella tendon force (2). The PCSA of each quadriceps muscle was calculated by diving the volume measured using magnetic resonance imaging by ultrasound measurements of fascicle length at MVC. The effective PCSA of the whole quadriceps was determined as the sum of the PCSAs of the four constituent muscles, each multiplied by the cosine of the appropriate pennation angle. The mean specific force of the quadriceps was then obtained by dividing FT by the sum of the effective PCSAs. RESULTS: Isometric torque increased by 33+-12%, (p<0.05) and total quadriceps ACSA increased by 5+-4% (p<0.05); quadriceps volume increased by 6+-3% (p<0.05); quadriceps PCSA did not change significantly (5+-11%), quadriceps tendon force increased by 22+-18%, from 53+-9 N/cm2 to 64+-10 N/cm2 (p<0.05). DISCUSSION: The quadriceps specific tension values in this study are noticeably higher than those reported in single fibre studies. The increase in specific tension for the whole quadriceps group increased by 22+-18%, from 53+-9 N/cm2 to 64+-10 N/cm2 (p<0.05). DISCUSSION: The quadriceps specific tension values in this study are noticeably higher than those reported in single fibre studies. The increase in specific tension confirms previous reports (see reference 1) and was not explicable by changes in muscle architecture, activation and/or co-activation. It is still not clear what causes the large specific force values or increase in specific force with training but differences or changes in myofibrilar packing and lateral transmission of force remain possibilities to be examined.

INCREASED SOLEUS H-REFLEX EXCITABILITY DURING UNILATERAL LOWER LIMB SUSPENSION IS NOT ACCOMPANIED BY CHANGES IN DESCENDING NEURAL DRIVE
Seynnes, O., Maffiuletti, N., Horstman, A., Narci, M.
Manchester Metropolitan University, United Kingdom

While a decrease in voluntary activation capacity is typically observed following unloading or immobilisation (2, 3), several authors have reported an increase in resting Hoffmann reflex (H-reflex) excitability with this type of intervention (1, 2). By measuring an electromyographic variant of H-reflex, the volitional wave (V-wave), the purpose of the present study was to investigate whether the gain in H-reflex excitability induced by unilateral lower limb suspension (ULLS) were associated with changes in efferent neural drive to the planar flexor muscles.

Six male volunteers (23 ± 2 yr, 187 ± 6 cm, 79 ± 9 kg) completed 24 days of ULLS. Outcome measures included plantar flexor maximal voluntary contraction (MVC) force, and activation capacity (twitch interpolation), and soleus maximal electromyographic (EMG) activity, H-reflex and V-wave. Following ULLS, MVC force decreased by 15% (P<0.05). However, neither plantar flexor activation capacity nor soleus maximal EMG activity was significantly altered after the suspension. Consistently, V-wave remained unchanged after ULLS while H-reflex significantly increased (+20%). Furthermore, there was no significant relationship between changes in H-reflex and V-wave over the ULLS period. Unexpectedly, these findings indicate that 24 days of ULLS can result in a substantial reduction of muscle strength without any apparent change in efferent neural drive. Combined H-reflex and V-wave, measured for the first time in the context of unloading, suggest that the spinal adaptations underlying the unloading-induced increase in soleus H-reflex excitability did not significantly affect the efferent motor output to the plantar flexor muscles. These results indicate that the unloading-induced decrease in neural drive observed in other disuse paradigms is mitigated with ULLS. Consequently, the loss in muscle strength observed in the present conditions is likely explained by muscle atrophy and, possibly, by a reduction in single fibre specific tension.

MANUAL PREFERENCE IN INDIVIDUALS WITH AUTISM SPECTRUM DISORDERS
Correia, N., Silva, A., Vasconcelos, O.
Associação Portuguesa para as Perturbações do Espectro do Autismo Norte, Portugal

The Autism Spectrum Disorder (ASD) is a global development disorder (Marques, 2000). Left-handedness or an ambiguous manual preference reveals a higher incidence in people with ASD than in general population, about 18% and 36%, correspondingly (McManus and Cornish, 1997; Hauck and Dewey, 2001). These values also seems to match with ASD mental retarded subjects (Bradshaw et al., 1996). The aim of this study was to assess manual preference in two groups, ASD and non clinical subjects. The sample comprises 130 subjects of both sexes, between 16 and 46 years old, divided in two groups. The ASD group had 65 subjects and the nonclinical group
had 65 impaired normal subjects. Subjects’ manual preference was assessed through a simple task, consisting in picking up ten objects, situated on a table, in the midline of the subject’s body. It was observed the chosen hand to pick up each of those objects. Results showed that the ASO group presented a higher percentage of left-handers (35.3% in males, 50% in females) when compared with their counterparts (7.8% in males, 7.1% in females). All differences between groups were statistically significant. The results of our study presented, as we expected, that the ASD subjects’ left-handed percentage is significantly higher when compared with that of the non clinical group. In the same way, Bradshaw et al. (1996) and Comish and McManus (1997) had already observed similar values in their studies. We’ve verified that the percentage of left hander’s in our study (38.5%) is higher than in Bradshaw et al. (1996) (18% of ASD subjects left-handers). However the values of ambiguous manual preference reach 36% in populations with PEA.

A HOME-BASED AEROBIC EXERCISE TRAINING PROGRAMME IS SUCCESSFUL AT IMPROVING CARDIOPULMONARY AND QUALITY OF LIFE OUTCOMES IN BREAST CANCER SURVIVORS

Hewitt, J., Mokbel, K., Jewell, A., Garrad, R., Van Someren, K.

Kingston University, United Kingdom

BACKGROUND: Recovery from breast cancer and its treatment has been reported to leave the majority of survivors with some form of fatigue, impairing quality of life (QOL). Exercise has been shown to be an effective strategy in combating such fatigue, and for improving the QOL of survivors. Consequently there is a requirement to develop easy and effective exercise strategies to improve physical capacity and patient well-being. PURPOSE: To determine the effects of a home-based 12-week aerobic exercise training programme on cardiopulmonary function and QOL within breast cancer survivors. METHODS: Forty breast cancer survivors were randomly assigned to an exercise (E) (n = 25, mean ± SD age 48 ± 9 years, body mass 67 ± 11 kg) or control (C) (n = 15, mean ± SD age 52± 8, body mass 71 ± 13 kg) group. E was prescribed a progressive aerobic training programme to be performed 4 times a week for 8 weeks liminal intensity 65% peak oxygen consumption (VO2 peak), and to be conducted without further advice for another 4 weeks. C was instructed to maintain their current physical activity level. VO2 peak, peak heart rate (PHR), oxygen economy at 2 minutes (VO2 2min), 4 minutes (VO2 4min), systolic blood pressure (SBP), diastolic blood pressure (DBP), BMI and QOL were determined in both groups pre-intervention and at 4-weekly intervals. Both groups completed a weekly Leisure Time Questionnaire to quantify additional exercise load. RESULTS: E completed 86 ± 6 % and 87 ± 10 % of sessions week 1-4 and week 4 8, but only 76 ± 14 % of sessions week 8 12. Non-protocol related exercise was not significantly different between groups at any time point (P > 0.05). There were no significant differences pre-intervention for any of the variables tested (P > 0.05). There was a significant time and interaction effect for VO2 peak (P < 0.05), but no treatment effect (P > 0.05). Post-hoc tests revealed a significant increase in E VO2 peak at week 4, 8 and 12, but no significant differences in C at any time point (P > 0.05). There was a significant time effect (P < 0.05), but no interaction or treatment effect (P > 0.05) for PHR. Post-hoc tests revealed a significant decrease in E at week 4 and a significant increase in C at week 4 and 12 (P < 0.05). There was no significant time, treatment or interaction effect for SBP (P > 0.05), but there was a significant time effect for DBP (P < 0.05). Post-hoc tests revealed a significant decrease in E at week 8 and 12, but no significant differences in C at any time point (P > 0.05). There was a significant time and interaction effect for QOL (P < 0.05). Post-hoc tests revealed a significant improvement in E at week 4, 8 and 12 (P < 0.05), but no significant differences in C at any time point (P > 0.05). CONCLUSIONS: A 4 times a week home-based aerobic exercise programme can successfully improve physical capacity and improve QOL among breast cancer survivors.

SELECTIVE WEAKNESS AT SHORT MUSCLE LENGTHS AFTER STROKE

Horstman, A., Gerrits, K., Beltman, M., Janssen, T., De Haan, A.

Research Institute MOVE, Netherlands

The majority of people after stroke have muscle weakness contralateral to the brain lesion, which causes problems in functional tasks like balancing, walking and transfers. Strength is proved to be affected by muscle length and this length-dependency of force generation contributes to the torque-angle relationship found in healthy humans (1), which is an important feature, since a whole range of muscle-lengths is used during daily activities. In stroke patients, knee extensor muscle function appears to be more affected when the knee is in the last 0-15º of extension (2). However, knowledge about possible length-effects of the thigh muscles, which are very important for mobility in daily life, is not available. Therefore, the purpose of this study was to investigate whether muscle function is selectively more affected as result of stroke at lower lengths of the thigh muscles and further to determine whether this selective weakness can be attributed to impaired activation at different muscle lengths. Therefore, maximal voluntary isometric torques of knee extensors and flexors were measured in 3 knee angles (30, 60 and 90º) in 14 stroke patients (bilaterally) and 12 healthy control subjects. Simultaneous measurements were made of agonist torque and surface EMG (sEMG) from agonist and antagonist muscles. Maximal voluntary torque and sEMG data were normalized to the values obtained at 60º knee angle for extension and 30º for flexion. At 30º knee angle, the extensor torque of the paretic lower limb (PL) was 73% of the torque of control subjects and knee flexor torque at 60º and 90º knee angles was 64% and 45% of control subjects, respectively. Thus, muscle function was selectively affected at lower muscle lengths of the knee flexors and extensors as result of stroke. Normalized knee extensor sEMG was significantly lower in P compared to controls (~71%) at 30º knee angle. Although not significant, mean values for the paretic knee flexors muscles in 60º and 90º were ~79% and ~67% of control, respectively. It is concluded that as result of stroke the lower muscle torque at lower muscle lengths of the knee extensors is caused by a length-dependent lower voluntary activation capacity, which may also be the case for the flexor muscles. From these results, it is recommended to investigate the role of specific training of the knee flexors and extensors of the (paretic) lower limb in especially the shortened position to improve the recovery of function after stroke.
MOTOR LEARNING THERAPY IN PARKINSON’S DISEASE: A LONGITUDINAL TRIAL

Buehlmeyer, J., Alf, W.
University of Stuttgart, Germany

Idiopathic Parkinson’s disease (PD) is a neurodegenerative disorder. Apart from pharmacological treatment, movement therapy shows positive effects on motor symptoms. There is evidence that automated movements of PD patients rely on impaired neural networks subserving the basal ganglia. Replication of these impaired movement patterns will probably not have a great effect in movement therapy. Therefore, we raise the hypothesis that, in addition with pharmacological treatment, movement therapy with a high demand on motor learning is more effective in maintaining motor performance of mild to moderate affected PD patients than movement therapy with well-known motor tasks.

Methods: 30 PD patients on stable medication (6.5±10 years, stage 2-2.5 according to Hoehn & Yahr stage) were included as subjects. The patients were tested in equal intervals of three weeks over a period of 9 weeks (4 baseline tests) before starting the training interventions. Subsequently they were divided according to sex, age, and physical activity level into training group A (steady contents therapy, consisting of gait, endurance, strength, flexibility training) and group B (new contents therapy, composed of motor learning of new and alertness demanding impulses). During the 12-week training period, patients were examined in the same intervals as during pre training (4 training tests). We collected norm data from 15 healthy age matched adults (64±4 years) that completed the test protocol once. The test protocol included biomechanical analysis of fine motor dexterity, reaction and aiming tasks, fast repetitive movements, postural stability, activities of daily living like standing up and gait using electromyography and goniometry. Beside this, a neurologist assessed the disease score (UPDRS, Unified Parkinson Disease Rating Scale) in the same intervals.

Results and Discussion: Neurological measures of the UPDRS reveal a decline in motor performance during the test period. Biomechanical parameters like muscle onset, movement time and movement precision in the acyclic movements aiming and reacting are good predictors to detect differences between healthy and neurological disabled individuals. Improvements during the therapy period could be detected in group A. Electromyographic parameters e.g. co-activation of flexor and extensor muscles in cyclic movements (hand tapping/ping/gait) reveal changes during the training period and can be used to detect differences between the more and the less affected body side of the patients. Modulations on the kinematic level were observed, regarding variability, and movement amplitude in gait. Differences between the groups are not consistent in all test situations, suggesting that different therapy strategies and/or diverse contents result in different effects on motor performance of the patients. However, we assume that the use of the spinal motor neuron set via unimpaired pathways can be accounted for changes on neuromuscular level that occurred.

EVALUATION OF A PROGRAM OF ADAPTED PHYSICAL ACTIVITIES FOR PATIENTS WITH CHRONIC LOW BACK PAIN WHO COMPLETED A FUNCTIONAL MULTIDISCIPLINARY REHABILITATION

Henchoz, Y., de Gourmonts, P., Norberg, M., Pailllex, R., So, A.
Institute of sport sciences and physical education, Switzerland

INTRODUCTION

Low back pain is a major health and socioeconomic problem in Western countries and is associated with high costs for the individuals and the health care system [1]. Among the many treatment modalities, functional multidisciplinary rehabilitation (FMR) seems to be the best strategy [2]. Post-FMR, the patient traditionally manages the problem himself with his general practitioner. The aim of the present study was to compare, after a FMR, the effects of the traditional follow-up with the effects of a program of adapted physical activities (PAPA) on the patients’ symptoms and functional status.

METHODS

105 chronic low back pain patients having completed a 3 week FMR were randomly assigned to PAPA or a control group (classical follow-up). PAPA included 24 exercise sessions during 12 weeks. Each session lasted 1.5 hours and included warm-up, strengthening, cardiovascular endurance training and passive stretching under the supervision of a sport therapist. Patients underwent evaluations of trunk muscle endurance (Shirado and Sörensen tests), spinal mobility (Modified-modified Schöber and finger-to-floor tests), cardiovascular endurance (Modified Bruce test), and pain (Visual Analog Scale) at T0 (beginning of FMR), T1 (end of FMR) and T2 (end of PAPA/control). Questionnaires measuring disability (Oswestry) and quality of life (SF-36) were filled in at T1 and T2. Wilcoxon and Mann-Whitney tests were used for statistical analysis of SF-36, Friedman and Mann-Whitney tests for pain and all physical condition parameters, and t tests for Oswestry.

RESULTS

Between T0 and T1, both groups significantly improved on all measured parameters except Modified-modified Schöber. Between T1 and T2, all improved physical parameters were stabilised except the Modified Bruce test which significantly decreased in both groups. A significant improvement was noticed in 6 of the 8 scales of the SF-36 test for the experimental group and 3 scales for the control group. Oswestry significantly decreased for the experimental group but not for the control group. No between groups differences were found.

DISCUSSION/CONCLUSION

As expected, FMR lead to a significantly improved functional status of the patients. Following FMR, PAPA had significantly better effects on disability and quality of life than the classical follow-up. The effects on physical condition and pain were comparable. These short term results will be completed by a 1-year follow-up which is currently underway.

In conclusion, experimental and control groups both maintained the main functional improvements due to FMR after 3 months, but patients who followed PAPA also significantly improved quality of life and decreased disability, which should reduce absenteeism from work and health care costs.

COLD WATER CRYOTHERAPY AS A TREATMENT FOR MUSCLE SORENESS AND MUSCLE DAMAGE

Donnelly, A., Byrne, D., Buggy, P., Hoare, K.

University of Limerick, Ireland

Recovery from exercise is an increasingly important part of elite athletic performance. Cryotherapy is one treatment that has gained widespread popularity over recent years. However research into its benefits has provided equivocal results (Wilcock et al., 2006). The purpose of this study is to investigate the effectiveness of 4 minutes of cold-water cryotherapy as a treatment for muscle soreness and muscle damage. Twelve untrained volunteers, (7 male, 5 female) aged 20y (±1.2y) performed 100 maximal eccentric contractions of the knee extensors of one leg on an isokinetic dynamometer. Three weeks later they performed an identical bout using their contralateral leg. Following the bout they were treated either with 4 minutes standing in a circulating water cryotherapy tank (Hydrotherapy Solutions, MCL, Co. Tipperary, Ireland) or warm immersion (CON) immediately after and at 24, 48 & 72h after exercise, in a randomised crossover design. The CRYO water temperature was set at 6±1°C, the CON water temperature was 19±1°C. Isometric Maximal Voluntary Contraction (MVC) force, maximal isokinetic force (both concentric and eccentric), electrical stimulation force ratio (20Hz,50Hz) and muscle soreness (SOR) acted as indirect markers of muscle damage and were assessed before and on the days following the damaging protocol. Results were compared using repeated measures ANOVA.

The damaging protocol proved effective, inducing a significant decrease in MVC (P<0.001) in the days following the exercise bout. The CRYO group recorded a Day 3 mean MVC of 551N (±296N), 78% of pre-test! with the CON group recording a Day 3 mean MVC of 513N (±251N), 77% of pre-test. Maximal eccentric torque (P<0.05) and electrical stimulation force ratio (P<0.05) also decreased significantly over time. Perceived muscle soreness scores increased significantly post exercise bout (P<0.05) to 160 (±120; arbitrary value) for the CRYO group on Day 4 and to 157(±113; arbitrary value) for the CON group on Day 3. However, while both treatment groups displayed significant signs of muscle damage on the days following the exercise bout no significant differences were found between treatment groups for the variables measured.

Therefore, cold water cryotherapy when compared to immersion in room temperature water was not effective in reducing muscle soreness or altering changes in indirect markers of muscle damage. It is possible that other combinations of immersion durations or water temperatures might produce differing results.

ALTERATIONS OF SEVERAL SEMEN PARAMETERS AMONG PRACTITIONERS OF THREE DIFFERENT TRAINING MODALITIES

Vaamonde, D., Da Silva Grigoletto, M., Oehninger, S., Swanson, R., García-Manso, J., Lancho, J.

University of Cordoba, Spain

INTRODUCTION

Sports activities are in rising demand since physical exercise is promoted for improving life quality, but without an adequate knowledge negative side effects may appear. A number of studies report effects of exercise on reproductive health, association mainly assessed in females due to unequivocal symptoms. Later, alterations in male athletes’ reproductive function were also reported with exercise volume thought to have greater impact; intensity was suggested later as equally or more deleterious than volume(1). We hypothesize that continued practice of different modalities, due to inherent characteristics (volume, intensity, etc.), can result in differences in semen parameters. Thus, it is the aim of this study to analyze the semen profile of three populations with different type and level of physical activity.

METHODS

Semen samples of 16 physically active subjects (PA), 14 water polo players (WP), and 15 triathletes (TA) were evaluated. The exclusion criteria were any factors that could interfere with semen production. The inclusion criteria were: not having any exclusion criteria, mini-mum practice of 3 hours/week and VO2max >/= 40 ml/min/kg. Macroscopic and microscopic observations of physical and qualitative parameters of sperm were performed (3-6 days of abstinence) assessing ejaculate volume (ml), sperm concentration (million/ml), total sperm number (million), and velocity type (a, b, c, d) according WHO’s guidelines. One-way ANOVA showed statistical differences for age, thus ANCOVA was used for further comparisons. The pos-Hoc comparisons used the Bonferroni correction.

RESULTS

Sperm concentration, total sperm number, and type a, b and d showed differences (P<0.05); no differences were observed in ejaculate volume or type c velocity. Sperm concentration, total sperm number, and type b velocity values were higher in PA than in TA (P<0.05). Type a velocity was lower in WP than PA and TA (P<0.05). On the other hand, the number of immotile sperm (type d velocity) was higher for TA than PA (P<0.05).

DISCUSSION AND CONCLUSIONS

Our main finding is that there are differences in semen parameters among the three groups. The PA group shows a trend for higher values, in agreement with results reported by other authors, and also reported previously by our group. The TA group shows poorer parameters, TA has greatest training volume and intensity, which agrees with the volume threshold hypothesis. Likewise, some studies with bikers, runners, and swimmers report some differences in semen parameters. In conclusion, there are differences in the seminalogical profiles of individual exercising in different modalities; those systematically undergoing high training loads showed lowered values for semen parameters. However, a less demanding activity does not seem to alter them.

PHYSICAL ACTIVITY, ENERGY INTAKE AND BODY FAT AND ITS RELATION TO AEROBIC FITNESS IN ADOLESCENTS

Berntsen, S., Loedrup, C., Anderssen, S., Mowinckel, P., Koerner Bueso, A., Carlsen, K.
Norwegian School of Sport Sciences and Ullevaal University Hospital, Norway

Background: Aerobic fitness is associated with physical activity in adults, whereas results are conflicting among children and adolescents probably due to methods of physical activity and aerobic fitness measures. The present study aimed to determine whether objective measured physical activity, energy intake and body fat is related to aerobic fitness in adolescents with and without asthma.

Methods: 174 adolescents [3-14yrs], 52 with current asthma (40 boys), 43 with asthma ever (25 boys) and 79 controls (41 boys) performed maximal running on a treadmill with oxygen consumption measurements. Peak oxygen consumption was defined as aerobic fitness. Sum of four skinfolds were measured, and the participants wore an activity monitor, SenseWearTM Pro2 Armband (BodyMedia, Inc., Pittsburgh, PA, USA), and recorded diet using validated pre-coded food diaries for four consecutive days. Analysis of covariance was performed adjusting for gender, age and pubertal stage in all models.

Results: We found no indications of any differences between adolescents with and without asthma in physical activity variables, aerobic fitness, sum skinfolds or energy intake. Consequently, we present analyses for pooled data only. Very vigorous physical activity alone explained 17% of the variability, and 60minutes daily increase in very vigorous physical activity was associated with 5.1 (95%CI: 2.7-7.6) ml/min/kg increase in aerobic fitness (p<0.001). Moderate and vigorous physical activities were not included in the final model (not significant). An inverse association was found for sum of four skinfolds and 10 mm reduction in sum of four skinfolds increased aerobic fitness with 2.9 (2.1-3.7) ml/min/kg (p<0.001). There was a positive association between energy intake and aerobic fitness (p=0.04). The variables included in the final model explained 56% of the variability in aerobic fitness.

Conclusions: The number of hours with very vigorous intensive physical activity is associated with aerobic fitness, although weakly. Sum skinfolds is associated with lower aerobic fitness.

IMPACT OF POLLUTION, HEAT AND HUMIDITY ON THE ACTIVATION OF AIRWAY INFLAMMATION IN ATHLETES PERFORMING AN 8 KM TIME TRIAL RUN

Couto, G., Florida-James, G., Stone, V.
Norwegian School of Sport Sciences and Ullevaal University Hospital, Norway

One of the primary pollutants of concern to athletes competing in the Beijing Olympic Games 2008 will be the oxidant gas ozone (O3), especially when combined with the heat and humidity (H) of the summer months. Ozone has been shown to induce lung inflammation and decrease lung function. Clara cell protein (CC16) has been shown to be a sensitive biomarker of lung injury that occurs with exposure to pollutants. Together with other inflammation markers, such as IL-6, IL-8 and LDH, CC16 can be measured in nasal lavage, reflecting the inflammatory process in the upper respiratory airways.

AIM: To investigate the impact of a hot, humid and ozone-polluted environment during an 8 km time trial run on the activation of inflammation measured by the concentration of CC16, IL-6, IL-8, LDH and neutrophil count in nasal lavage. Additionally, C-reactive protein (CRP) and plasma CC16 were also measured.

METHODS: Using a single blinded randomized design, 10 male endurance athletes (mean (SD): 24 (5) years; 73 (7) kg; 181 (8) cm; 64.4 (3.6) ml/min/kg, 56% H, 54% H) performed an 8 km time trial run in four different environmental conditions: 20 degrees Celsius (Control), 20°C + 50% H + 0.10 ppm O3 (Control + O3); 31°C + 70% H (Heat); 31°C + 70% H + 0.10 ppm O3 (Heat + O3). The athletes' performance was measured by the total time to complete each trial. Nasal lavage and blood samples were collected post-exercise. Data was analysed using repeated measures ANOVA with Tukey's post-hoc test.

RESULTS: The total time to complete the Heat (32m35s) and Heat + O3 (33m09s) trials were significantly higher when compared with the Control (29m33s). Even though there is no statistical difference between the Heat and the Heat + O3 trials, the time to complete the latter was, on average, 3.4 sec longer when compared to the former. In a competitive 8 km race environment, this time difference could be very important. Nasal lavage CC16 levels showed an increase in the Heat + O3 trial compared to the Control; however, no differences were found in the plasma concentration. The IL-6 levels could not be measured in the nasal lavage and no differences were found in either the IL-8 or in the LDH concentration. There was an increase trend in the CRP plasma levels for the ozone trial and the Heat trial, with the Heat + O3 presenting the highest CRP concentration. Even though there was no statistical increase in the neutrophil counts, an increase in all trials when compared to the Control was observed. In addition, some athletes appeared to experience different toxic effects when exposed to ozone, suggesting an individual intrinsic response to the inflammatory effects of this pollutant.

CONCLUSION: In the conditions studied, ozone alone did not impair performance or activate lung inflammation. Nevertheless, when combined with heat and humidity, significant performance decrements occurred together with an increase in some inflammatory markers.

THE EFFECTS OF EXERCISE INDUCED MUSCLE DAMAGE ON SENSORIMOTOR AND NEUROMUSCULAR PERFORMANCE IN MALES

Tsakiris, A., Gleseson, N., Eston, R., Minshull, C.
University of Exeter, United Kingdom

Optimal functioning of the musculature in a timely manner is paramount to the dynamic stabilisation of synovial joints. It is plausible that exercise-induced muscle damage (EIMD) might be an important determinant of the extent of injury-risk and influence performance capabilities including muscle activation patterning and sensorimotor control at the extremes of the joint’s range of motion. The aim of this study was to assess the effects of EIMD on sensorimotor and neuromuscular performance in males.

Peak force, electromechanical delay, sensorimotor performance (force error relative to a ‘blinded’-target) capabilities and descriptive markers of EIMD (perceived muscle soreness, passive hip flexibility) were assessed in ten males (age: 20.9 ± 2.3 yr; height: 1.78 ± 0.06m, body mass: 72.3 ± 7.4kg [mean ± SD]) prior to and at 0.5h, 24h, 48h, 72h following a damaging exercise protocol incorporating six sets of 10 isokinetic eccentric contractions of the ipsilateral knee flexors. Neuromuscular and sensorimotor assessments were completed at 30 degrees of knee flexion. Results showed that while performance capabilities remained constant in the control period and contralateral control leg, the EIMD intervention provoked reduced performance of the involved leg compared to pre-intervention levels in peak force (33.7%: 259.2 ± 69.8 N versus 166.7 ± 45.1 N [pre- versus post-48h], F4,36) = 3.3; p<0.05), passive hip flexibility (22.5%: 0.268 ± 0.083 m vs. 0.205 ± 0.064 m [pre- vs. post-72h], F4, 36) = 10.9; p<0.001), electromechanical delay (32.7%: 55.1 ± 5.2 ms vs. 84.0 ± 5.9 ms [pre-
MUSCULOSKELETAL INJURIES ON PROFESSIONAL DANCERS IN PORTUGAL

Azevedo, A., Oliveira, R., Fonseca, J.
Faculdade de Motricidade Humana, Portugal

Introduction.

Dance is a predisposing profession to the occurrence of injury, being physically and psychologically demanding, with different risk factors. General purpose: To determine the annual prevalence of injuries on professional dancers in Portugal and to characterise associated its risk factors.

Methods.

In this epidemiologic retrospective study, each participant completed a self-completing questionnaire that collected information about the personal data, professional activity and occurrence of injuries. 193 questionnaires were distributed among 17 professional dance companies. We have used the Spearman correlation test and the Chi-square association test to treatment of the data. The significance level was decided from p<0.05.

Results.

The population consisted of 1,791 skaters and 2,347 riders. They sustained respectively 209 and 341 injuries that were registered in BIS.

The overall incidences injuries per 1,000 hours of sport were for ice skating 3.7 and for horseback riding 1.1. The incidence during matches was higher than during training: ice skating training 2.1 and match 8.6 and horseback riding training 0.9 and match 2.4.

For both sports most injuries were new, acute (skating 73%, riding 90%), often falling accidents (skating 37%, riding 72%) and haematomata/contusion/bruises (often in combinations with other diagnosis) are common (skating 30%, riding 56%).

The most injured body part in skating is the knee (20%), acute injuries are also often head injuries (8%) and overuse injuries are often localised in the lower back (16%). In riding the most injured body parts are the head (16%) and also the lower back (15%). A striking difference is: skaters don't wear helmets (2%) and riders do wear helmets (81%).

Conclusions.

In general the web based registration works well and provides more detailed information on sports injuries in ice skating and horse back riding than other Dutch registration systems. The Royal Dutch Skating Union and the Foundation Safe Horse Back Riding can improve their preventive policy by

WEB BASED SPORTS INJURY REGISTRATION; ICE SKATING AND HORSEBACK RIDING

Van Hespen, A., Stubbe, J., Vreede de, P., Stege, J., Ooijendijk, W.
TNO Quality of Life, Netherlands

Background

The number of sports injuries in the Netherlands is about 1,5 million every year. The yearly costs are high and sports injuries are an important cause for people to stop participating in sports. For the Ministry of Health, Welfare and Sports these are important reasons to invest in adequate registration and prevention of sports injuries.

TNO developed a web based registration and information system called BIS (Injury Information System) to gain insight in the frequency, the characteristics and the consequences of sports injuries and the effects of preventive measures. BIS is operational for 18 sports: badminton, dancing, fitness, futsal, gymnastics, hockey, horse back riding, ice skating, judo, karball, running, lamateur and professional, skating, soccer, squash, swimming, tennis, volleyball and winter sports. The results for ice skating and horseback riding will be presented.

Methods.

The study was designed as a retrospective cohort study of sports injuries by means of a web-based survey. A cohort of skaters and a cohort of riders were asked to fill in a web-based questionnaire. Information was gathered on background, sports injuries and recovery. In the communication to the skaters and riders safety was emphasized to stimulate not only injured but also not injured skaters and riders to fill in the questionnaire. The skaters were licence holders of the Royal Dutch Skating Union, members of skate schools and other skate clubs. The riders were visitors of the Horse Event in Deurne in the Netherlands, members of the newsletter Horses.nl and members of a newsletter for owners of riding passports of the Federation of Dutch Riding Accommodations.

Results.

The population consisted of 1,791 skaters and 2,347 riders. They sustained respectively 209 and 341 injuries that were registered in BIS.

For both sports most injuries were new, acute (skating 73%, riding 90%), often falling accidents (skating 37%, riding 72%) and haematomata/contusion/bruises (often in combinations with other diagnosis) are common (skating 30%, riding 56%).

The most injured body part in skating is the knee (20%), acute injuries are also often head injuries (8%) and overuse injuries are often localised in the lower back (16%). In riding the most injured body parts are the head (16%) and also the lower back (15%). A striking difference is: skaters don't wear helmets (2%) and riders do wear helmets (81%).

Conclusions.

In general the web based registration works well and provides more detailed information on sports injuries in ice skating and horse back riding than other Dutch registration systems. The Royal Dutch Skating Union and the Foundation Safe Horse Back Riding can improve their preventive policy by

VERSUS POST-0.5h [F(4,36) = 6.5; p <0.01] and sensorimotor performance (5.8% [0.3 ± 3.7% vs. 6.1 ± 5.9%] [pre- versus post-24h]; F(4,36) = 5.9; p <0.05). Performance capabilities had not recovered significantly 72 hours after the damaging protocol.

The EIMD-related sensorimotor and neuromuscular performance deterioration was prominent for 72 hours and was sufficiently potent to raise concerns about a commensurate loss of capability for rapid and dynamic stabilisation of synovial joints during episodes of threat from injury.
In many daily activities as well as during sport, there is an interaction between the human system and elastic or viscoelastic surfaces. Although in many cases, such as the interaction human-shoe, the energy exchange is too small to have a direct effect on energy expenditure, in other cases the interaction between the surface and the human body has a significant influence on performance. The human system is able to adjust its behavior to the different surfaces which it is interacting with or use these systems to improve their own motor performance. Precisely this has been happening in the sport context, where modifying the interactions between athlete and elastic or viscoelastic surfaces is able to adjust its behavior to the different surfaces which it is interacting with or use these systems to improve their own motor performance. In a series of experiments we examined the effect of the interactions between athlete and elastic surfaces (i.e. high bar, uneven parallel bars and pole vault) on the performance capability. Athletes use the elastic surface during this interaction by (a) store part of their kinetic energy as strain energy and convert this strain energy into potential energy and (b) produce muscular work to increase the total energy.

Furthermore, it is well accepted that the non rigidity of the tendon and aponeurosis allow the muscle fibres to contract at lower shortening velocities than the whole muscle-tendon unit and as a consequence of the force-velocity relationship their force generating potential will be higher. Due to the non rigidity of the tendon and aponeurosis, when the muscle-tendon unit is elongated, strain energy can be stored. This way the whole energy delivered during the shortening of the muscle-tendon unit can be enhanced. Therefore, in a second series of experiments we examined the mechanical properties of the lower extremities muscle-tendon units (MTU) from athletes displaying different stiffness in the triceps surae MTU and a higher compliance of the quadriceps tendon and aponeurosis at low level tendon forces. The faster sprinters exhibited a higher elongation of the vastus lateralis (VL) tendon and aponeurosis at a given tendon force and a higher maximal elongation of the VL tendon and aponeurosis during the MVC. Furthermore, the maximal elongation of the VL tendon and aponeurosis showed a significant correlation with the 100 m sprint times ($r = -0.567$, $P = 0.003$). It has been supposed that, the more compliant quadriceps tendon and aponeurosis will increase the energy storage and return as well as the force potential of the muscle due to the force-velocity relationship. A higher force potential of the muscle would decrease the volume of active muscle at a given force decreasing the cost of force production, or increase the force at a given activation.
BIOMECHANICS IN ALPINE SKIING: APPLICATION AND SCIENTIFIC SUPPORT IN ELITE SPORT

Spitzenpfeil, P., Huber, A., Waibel, K.
Technische Universität München, Faculty of Sports Science, Germany

Modern alpine ski racing is characterized by high acting forces in combination with the challenge of keeping the balance and the ideal loading of the ski. Therefore biomechanical diagnostics on the one hand is focused on those acting forces and the corresponding strength abilities of the athletes, on the other hand is trying to measure, evaluate and improve movement abilities during skiing. This paper tries to show the application of different biomechanical methods and results in the concept of the scientific support of the German Ski Team in cooperation with the Olympia-Aetzpunkt Bayern and the Technische Universität München.

To measure the acting forces during skiing two general systems are used. The first consists of a force plate mounted between ski and binding collecting data of forces (Fz) and moments (mx, my). The raw data are transmitted wireless, evaluated in real-time and synchronized to the video recording. Right after the run, information about the loading position and posture can be given to racers and coaches. The second measurement system is a pressure insole device (Parotec, Paromed, Germany) which is inserted into the ski boots. Data are stored in a data logger and the runs are video recorded. The evaluations can be presented in breaks of the training session or after the training. For certain analyses additionally knee angles are measured by goniometry.

To assess the individual strength abilities of the racers maximal isometric (knee angles: 90°, 120°) and concentric/eccentric tests in different angular velocities (45°/s, 90°/s, 180°/s) on a leg press (Desmotronic, Schnell, Germany) are performed. Additionally speed strength is measured by common jumping tests as squat jumps and counter movement jumps on a force plate.

Results of the measurements in skiing approved the amount of acting forces known from literature in different disciplines in a range of 1500 up to 3500 N. Model based calculations also showed, that the racer has to sustain average maximum forces up to 2.5 g in GS and SG. Concerning the movement behaviour, the trainability of ideal positions in straight gliding could be shown as well as the importance of certain movement patterns during turns.

Relating the individual strength abilities to the measured acting forces in skiing by using different custom built models, the muscular expenditure of individual force production in skiing was estimated. Results show that in all measured cases the intensity of the estimated muscular expenditure in turns is higher than 50% of maximum tested in lab. The highest expenditure was recorded in SL with maximal intensities up to 100% depending on very low knee angles in some situations. However, the time of this maximum force production in SL is comparatively low. Averaging the values over 20s, the mean expenditure in all disciplines is about 40%. This indicates the high energy demands and needs of specific strength endurance abilities in alpine ski racing.

Invited symposia (IS)

IS-PM03 Features of the metabolic syndrome in children

PHYSICAL ACTIVITY AND CLUSTERED CARDIOVASCULAR RISK. WHY DO RISK FACTORS CLUSTER AND HOW MUCH ACTIVITY DO CHILDREN NEED? THE EUROPEAN YOUTH HEART STUDY

Andersen, L.B., Kristensen, P.L., Møller, N.C., Froberg, K.
University of Southern Denmark, Denmark

Background Atherosclerosis develops from early childhood. Physical activity (PA) may positively affect this process. The aim of the present study was to assess the associations of objectively measured PA with clustering of cardiovascular disease (CVD) risk factors in children and derive guidelines based on the analysis. Possible explanations for risk factors to cluster will be discussed.

Methods Cross sectional study of 1732 9- and 15-year-old randomly selected school children from Denmark, Estonia and Portugal. Risk factors included in the composite risk factor score (mean of z-scores) were systolic blood pressure, triglyceride, ratio total cholesterol:high density lipoprotein (HDL), insulin resistance (HOMA), sum of four skinfolds, and aerobic fitness. Subjects having a risk score above 1SD of the composite variable were defined to be at risk. PA was assessed by accelerometry. Findings Odds ratios for having clustered risk for ascending quintiles of counts per minute (cpm) were 3.29 (95% CI: 1.96-5.52), 3.13 (95% CI: 1.87-5.25), 2.51 (95% CI: 1.47-4.26), and 2.03 (95% CI: 1.18-3.50), respectively, compared to the most active quintile. The first to the third quintile of PA had elevated risk in all analyses. Fitness showed the same strength of association with the clustered risk score as did skinfold and waist circumference. Physical activity was associated with clustered risk even after adjustment for fitness and fatness with an odds ratio for the upper quintile of 1.81 (95% CI: 1.18-2.76).

Interpretation Clustered cardiovascular risk seems to be a plausible biological measure of metabolic health condition. Many physiological mechanisms may be responsible for risk factors to increase simultaneously, but most are related to physical activity or training. Physical activity, fitness and fatness may partly affect these mechanisms independently.

PREVALENCE AND CORRELATES OF THE METABOLIC SYNDROME IN CHILDREN

Ekelund, U.
MRC Epidemiology Unit, United Kingdom

The metabolic syndrome (MS) comprises visceral adiposity, hypertension, glucose intolerance and dyslipidaemia (elevated triglycerides and decreased HDL-cholesterol levels). The coexistence of multiple metabolic risk factors has recently been observed in children, likely driven by the increasing prevalence of obesity. However, until recently, no standard definition of the MS for use in paediatric populations was available. Consequently, researchers have used a plethora of definitions with prevalence figures of the MS in young people varying between 0% and 60%. Recently the International Diabetes Federation (IDF) released its guidelines for defining and diagnosing the MS in young people.

To develop a simple unified definition which can be used as a diagnostic tool for early detection of the MS in young people. According to this definition the prevalence of the MS was 5.2% in 14 year old US adolescents and 7.1% in 16 to 17 year olds US adolescents using data from the NHANES 1999 to 2004. Comparable data in European youths participating in the European Youth Heart Study suggest a substantially lower prevalence of 1.4% in the 15 year old boys and girls. A direct comparison between the 14-year-old US and the 15-year-old European adolescents revealed that these differences are explained by a higher prevalence of central obesity in US compared with European youth (25.6% vs. 16.4%). This despite remarkably higher cut offs for central obesity used in US adolescents. The
prevalence of hypertriglyceridemia (10.0% vs. 3.3%), and low HDL cholesterol levels (18.6% vs. 11.0%) were higher in US compared with European adolescents, whereas the prevalence of elevated blood pressure (4.9% vs. 5.3%) was similar. In opposite, the prevalence of hyperglycemia was slightly higher in European compared with US adolescents (17.6% vs. 14.2%). Similar to the observations in US youths, the prevalence of the MS increased with age, and was higher in males compared with females. Even if the absolute prevalence of the MS was low, more than 15% European youth were categorised at risk of developing the MS as they are either centrally obese (≥90 percentile for waist circumference) or had two or more of the other risk factors.

Cardio-respiratory fitness (OR=0.22, 95% CI: 0.07, 0.67), physical activity (OR=0.996, 95% CI: 0.993, 0.999) and maternal BMI (OR=1.12, 95% CI: 1.02, 1.2) were all independently associated with the MS after adjustment for sex, age group, study location, birth weight, and sexual maturity in European youth. Increasing daily moderate intensity physical activity by 10% to 20% above current levels was associated with a 33% risk reduction.

In summary, the prevalence of the MS is low in European youth but approximately 15 to 20% may be at risk of developing the syndrome. High maternal BMI, low levels of physical activity and cardio-respiratory fitness independently contribute to the MS in youth.

CHILDREN'S PHYSICAL ACTIVITY: FINDINGS OF ACCELEROMETRY AND GPS MONITORING

Cooper, A., Page, A., Jago, R., Hillsdon, M.

University of Bristol, United Kingdom

There is growing recognition of the role of the environment in influencing health and health behaviours, and an environment that encourages excess energy intake and reduced energy expenditure is widely considered to be a driving force behind population-wide weight gain. Expert bodies have highlighted the importance of environmental factors on obesity and there have been strong calls to focus on changing the environment. Physical activity is seen as an important behaviour to target for intervention and one behaviour that is readily amenable to change is active travel to school. Young people who walk or cycle to school have been shown to be more active than those travelling by car, often to a greater extent than may be explained by the journey itself (1,2). One potential reason for this may be greater play after school, and preliminary data suggest that boys who walk to school may spend more time in outdoor running/chasing games than car travellers (3).

To date, few studies have used objective measurement to investigate physical activity in the environment. The PEACH project is funded by the UK National Prevention Research Initiative to explore changes in physical activity behaviour and the personal, social and environmental correlates of physical activity across the transition from primary to secondary school. Thirteen hundred final year primary school children are currently being recruited in Bristol, England, and will be assessed 1 year later in their first year of secondary school. At both time points the participants wear an accelerometer (Actigraph GT1M) for 7 days to provide an objective measure of physical activity and the environmental context in which this activity takes place.

This presentation will describe the methodology for integrating accelerometer and GPS data recorded at 10-second epochs, and will present preliminary data from the PEACH project describing the association between active travel to school, children's physical activity and the environmental context in which this activity takes place.

ENVIRONMENTAL DETERMINANTS OF PHYSICAL ACTIVITY IN CHILDREN: FINDINGS FROM THE PEACH PROJECT

Page, A., Cooper, AR., Jago, R., Hillsdon, M.

The University of Bristol, United Kingdom

There has been considerable interest in recent years in the role of the environment in influencing physical activity. Studies of the effects of the environment on levels of physical activity have largely investigated perceptions of the environment. These perceptions include safety, availability and access, convenience, local knowledge and satisfaction, urban form, aesthetics, and supportiveness of neighbourhoods. However data outside the US and Australia is limited. This presentation will investigate the environmental factors which relate to objectively measured physical activity in children aged 10 to 11 years involved in the PEACH Project.

The PEACH project is funded by the UK National Prevention Research Initiative to explore changes in physical activity behaviour and the personal, social and environmental correlates of physical activity across the transition from primary to secondary school. Thirteen hundred final year primary school children have been recruited in Bristol, England, and will be assessed 1 year later in their first year of secondary school. At both time points the participants wear an accelerometer (Actigraph GT1M) for 7 days to provide an objective measure of physical activity and also wear a personal Global Positioning System (GPS) receiver after school. Participants also complete a detailed computerised questionnaire to assess personal, social and physical environmental determinants of physical activity.
Data presented will include measures of ‘independent mobility’ or freedom to roam unsupervised and how these relate to other more established perceptions of the environment. The presentation will also outline how perceptions of the environment can be linked to more objective data provided by the GPS to provide, for example, more expansive measures of time outside and its relationship to physical activity and adult supervision.

ASSOCIATIONS BETWEEN CHILDREN’S ACTIVITY AND FEATURES OF THE METABOLIC SYNDROME: EFFECT-MEDIATION BY FITNESS AND FATNESS

Brage, S.
MRC-Epidemiology Unit, United Kingdom

The metabolic syndrome may be defined as the co-existence of multiple metabolic risk factors. In adults, the syndrome increases the risk of cardiovascular disease and type 2 diabetes.

It has recently been recognized that metabolic risk factors also cluster in young people but less so in those who are physically active. These associations may be mediated or indeed modified by fitness and fatness, which would suggest that primary prevention could be targeted at certain high risk groups to maximize cost-effectiveness. The interpretation of existing data which forms the basis of such public health strategies is, however, made difficult by different definitions of metabolic dysfunction and differential measurement error and sources of bias in the exposure variables. The reason why these issues are important is that prevention strategies may look rather different if the primary purpose is to improve fitness and/or promote weight loss, compared to adapting a more general physically active lifestyle without any change in fitness or fatness.

This talk will discuss how these issues may be addressed in the interpretation of data from population studies using data from the European Youth Heart Study.

Oral presentations (OP)

COACHING THE SCANDINAVIAN WAY? CASE STUDIES OF THE PEDAGOGY OF SUCCESSFUL SCANDINAVIAN TEAM SPORT COACHES

Ronglan, L., Pensgaard, A.
Norwegian School of Sport Sciences, Norway

Three recognized professional coaches in Norway and Denmark, having coached female national teams to Olympic and/or World Championship success, was selected as informants in this study. The aim of the study was to map and analyze these coaches’ pedagogical practices, particularly in terms of (a) their facilitation of a holistic learning environment, and (b) their use of problem based learning. The coaches and their teams were observed during training camps and matches, whilst the coaches were also subjected to in-depth interviews.

The three coaches were strategically selected to be able to study successful coaches who have adopted a more player-centered and holistic philosophy and approach than their colleagues. As a result of the internal logic of competitive sport, and the technologization processes going on, top level sport of today might constitute a single-tracked and even dehumanizing environment to the athletes. Within elite sport it is not easy for coaches to keep up a holistic approach to facilitate human development, even though recent coaching research has supported such an approach to the coaching process (Cushion, 2007). Investigating the three selected coaches might generate knowledge of how learning processes can be handled to combine success in elite sport with player development in a wider sense.

Analysis of the data identified four dimensions characterizing the coaches’ pedagogical practices. That is, they were (i) highly team-oriented, they initiated a variety of (ii) problem based learning situations, they organized activities to (iii) utilize and spread the qualities embedded in the team, and they strove to see each athlete as (iv) a ‘whole’ and individual person. Taken together their practices draw heavily on Lave and Wenger’s (1991) conception of situated learning within the team, and the coaches proposed learning as a process of participation in the community of practice. Emphasis was put on each player’s inclusion and contribution to the community, and the activities implied changing of locations, roles and constellations.

The pedagogical enterprise undertaken also brought consequences for the coaches’ role. Leadership was transformed from traditional instruction to emphasis on orchestration of team processes and optimizing the conditions for each team member to release their resources. Jones and Wallace’s (2005) conception of ‘coaches as orchestrators’ seems to fit well the practice of the three coaches under study, in terms of how they worked to influence and coordinate complex team processes.

PRE-DECISIONS, POST-DECISIONS AND BEHAVIOUR OF TOP HANDBALL COACHES DURING GAMES

Sequeira, P., Hanke, U., Rodrigues, J.
Sport Sciences School of Rio Maior, Portugal

Introduction
We consider very important to analyse and reflect about the behaviour of Top Coaches. Research the behaviour of Handball Coaches during a Handball game, through observation, is a way to help the development of handball and the coaches education. We think that the context plays an important role in this matter.

Aim of the study
The purpose of this study is to find out if the coaches’ behaviour during a game and their decisions before and after the competition are consistent or if there are any changes.

Methods
Our sample was composed by 6 handball coaches, 18 handball games and 36 interviews from the 2000/2001 and 2001/2002 season. We observed 3 games from each coach. The training sessions and the games were video taped. The results from the observation were based on the total game and training time.

We used the SOTA observation system (18 categories). The development of the interview was based on a previously established script and on the SOTA observation system. A common tape recorder was used to record the interviews. We used the method of content analysis that allows inferences about the production conditions of the communications, based on quantitative indicators or others. We compared the behaviour of the handball coaches between the games using descriptive statistic (Schmitt & Hanke, 2001).

Results
The categories with the highest results are Silent Observation (49.78%) and Prescriptive Information (18.65%).

Before the game the coaches’ main decisions are: win the game, athletes have a good performance, give much prescriptive instruction, some questioning, some positive evaluative instruction, put the athletes in pressure during a long period of time and spend some time in silent observation. After the game the coaches’ main decisions were: the aim of the game was achieved, gave much prescriptive information, some questioning, put the athletes in pressure during a long period of time, positive and negative affective interactions, spend short time with his assistance coach, not much time in silent observation and there will be relation of this game with the next training sessions.

Discussion/Conclusions
Concerning the results we identified that the coaches decisions before and after the handball competitions and their behaviour are not very consistent. We suggest research on this two topics with increase the number of coaches, games and training sessions and in another sports.

SOCcer COACHAS’ INSTRUCTION TO PREPARE THE ATHLETES TO THE GAME
Rodrigues, J., Crispim-Santos, A.
Escola Superior de Desporto de Rio Maior, Portugal

We think it is essential that the coaches’ instruction during a competition reveals a high congruency, because with that he can help the players to achieve a higher performance. Therefore the aim of the present study is based on the comparative analysis of the soccer coach instruction, between different moments in the competition.

Twelve games were analyzed. Each competition contained 3 different moments: before game, during game and half time. Six soccer coaches were observed in male senior teams on 2nd B Portuguese League. We used the System Analysis of the Information in the Competition (SAIC) as an instrument to collect data and evaluate the Instructions. We used an event recording, which was afterwards used to codify all information units in agreement with SAIC adapted system with 3 dimensions: objective, direction and contents of information. To be able to prove the existing differences between the 3 different moments in the competition, the statistical test of wilcoxon was used, with the error probability (p-value) <=0.05.

Before the game Vs. During the game - regarding the objective of the instruction, we verify significant differences on the prescriptive category, although in both moments this instruction comprehended 80%, concerning the direction of the instruction, the results revealed a significant difference on the most important categories, the information before the game was mainly focused on the team and during the game focused on the player; concerning the contents of the instruction, we found significant differences, because before the game, it exist a supremacy of psychological than tactical contents, although in both moments more than 75% of the instruction belonged to this two categories.

Before the game Vs. Half time - concerning the objective, more than 80% of the instruction doesn’t reveal any differences, and it’s mostly prescriptive, concerning the direction of the instruction, more than 60% of the instruction doesn’t reveal any significant difference, regarding the contents of the instruction, we verified similar results of the last comparison.

During the game Vs. Half time - concerning the objective, in both moments more than 75% of the instruction is prescriptive; concerning the direction of the instruction, clearly exists a significant difference, so during the game the instruction is mainly focused on the player, while at the half time the coach focuses on the whole team or on various groups; concerning the contents of the instruction, the majority of the instruction doesn’t show significant differences.

In a competition the information that is instructed by the coach has a strong remark on prescriptive and descriptive information regarding its objective and the contents are mainly tactical and psychological. We found some important specification but when compared with other moments, we can assume that the soccer coaches demonstrate a high congruence profile of instruction in competition.

EVOLUTION OF THE PROFESSIONAL PERSPECTIVES OF PHYSICAL EDUCATION AND SPORT STUDENTS DURING THEIR UNDERGRADUATE STUDIES IN THE PUBLIC AND PRIVATE SECTORS 2ND STUDY
Batista, P., Albuquerque, A., Pinheiro, C.
University of Porto; Higher Institute of Maia, Portugal

This study represents the intermediate stage of a wider research that has as its main goal to perceive the transformations that take place in Physical Education students during their course, on their professional perspectives and conceptions concerning Physical Education and Sport. The socialization of a teacher is preceded by experiences that mark the form as the future teacher values the experiences of its undergraduate studies, being the experiences as students pointed out as the most relevant in the period of pre-socialization. On the other hand, the transition from university to school is accompanied by the difficulty of linking the perspectives, knowledge and action priorities transmitted by university to those conveyed by teachers in schools, the cooperating teacher included. It is crucial to understand the role of the undergraduate studies in the transformation of the perspectives resulting from pre-socialization and the adaptation to the perspectives of the professionals, in order to improve the quality of the intervention at the undergraduate level.

The sample is constituted by 246 pupils from the 1º year and 30 student teachers (in both cases 50% of ISMAI - private and FADEUP - public). In the first case it was employed an inquiry with open and closed questions. For the treatment of the closed questions we used

STORIL / PORTUGAL, 09-12 JULY 2008
the basic descriptive statistics, and for the open questions the NVIVO program was used. For the analysis of the student teachers’ perceptions the material came from the final reports. All the mentions to the cooperating teacher were looked for and later transcribed and introduced in the NVIVO program. The analysis of the student teachers’ perceptions with regard to determination, tolerance and prevention of doping on a national and international level. Considering the huge doping scandals of the last ten years, controls and sanctions could not reduce doping in sport in a sufficient amount. Besides repressive measures, prevention is the only additional possibility to minimize doping changing especially doping attitude and willingness of athletes. Further the Conventions claim, that States Parties should encourage sports organizations and anti-doping organizations to implement ongoing education and training programmes and to promote anti-doping research in all fields of prevention, such as health consequences, behavioural and social aspects. Additionally the World Anti Doping Code demands, that the stakeholders should plan, implement, evaluate and monitor information and education programs and promote such research. The Sport Science Information Forum SPORTIF of the BISP, and SPORTDISCUS of the Sport Information Resource Centre, SIRC, were analyzed focussing on prevention, doping, violence and 80 original papers and also related articles detected in review articles since 2000 were evaluated. A lot of material on doping prevention measures, presentations and papers, can be found free accessible in the internet, too. If they were published from Anti Doping Organisations or from other stakeholders in this field they were collected and evaluated using criteria according primary, secondary and tertiary prevention and contents, target groups, and kinds of measures. The collected and evaluated results will be presented and analyzed for additional necessities. Prevention of drug abuse and violence and health prevention will be compared and a common basis will be shown for use in doping prevention, too. A model of prevention measures including the primary, secondary and tertiary level will be shown with special aspect to the tertiary level. How we have to deal with athletes, who had doped to prevent relapses and avoid negative feedback to young athletes. The cooperating teacher and the supervisor distribute, now, this desideratum.

Belonging to two different institutions did not reveal to be a factor of differentiation relatively to previous conceptions about what it is a “good teacher”. Concerning the evolution from the 1st to the 2nd moment it is evident that: the factors related with the moral dimension, innovation, persistence, efficiency, devotion are little valued; the mastery of the teaching techniques is the most valued category and the student teachers recognize in the cooperating teacher a plurality of roles. The cooperating teacher is recognized as a person that supports them in the professional aspect as well in their personal and human aspects.

NEW ASPECTS IN DOPING PREVENTION

Mueller-Platz, C.
Federal Institute of Sports Science, Germany

The purpose of the Anti-Doping Convention of the Council of Europe and the International Convention against Doping in Sport is to promote the fight against doping in sport, with a scope on the reduction and elimination of doping in sport. The World Anti Doping Code claims measures with regard to detection, deterrence and prevention of doping on a national and international level. Considering the huge doping scandals of the last ten years, controls and sanctions could not reduce doping in sport in a sufficient amount. Besides repressive measures, prevention is the only additional possibility to minimize doping changing especially doping attitude and willingness of athletes.

Further the Conventions claim, that States Parties should encourage sports organizations and anti-doping organizations to implement ongoing education and training programmes and to promote anti-doping research in all fields of prevention, such as health consequences, behavioural and social aspects. Additionally the World Anti Doping Code demands, that the stakeholders should plan, implement, evaluate and monitor information and education programs and promote such research.

The Sport Science Information Forum SPORTIF of the BISP, and SPORTDISCUS of the Sport Information Resource Centre, SIRC, were analyzed focussing on prevention, doping, violence and 80 original papers and also related articles detected in review articles since 2000 were evaluated. A lot of material on doping prevention measures, presentations and papers, can be found free accessible in the internet, too. If they were published from Anti Doping Organisations or from other stakeholders in this field they were collected and evaluated using criteria according primary, secondary and tertiary prevention and contents, target groups, and kinds of measures.

The collected and evaluated results will be presented and analyzed for additional necessities. Prevention of drug abuse and violence and health prevention will be compared and a common basis will be shown for use in doping prevention, too. A model of prevention measures including the primary, secondary and tertiary level will be shown with special aspect to the tertiary level. How we have to deal with athletes, who had doped to prevent relapses and avoid negative feedback to young athletes. Finally the lack of knowledge to boost the effectiveness of preventive measures will be elaborated.

Oral presentations (OP)

OP-PM04 Physiology 4 - Neuromuscular

NEUROMUSCULAR FATIGUE DURING TRICEPS SURAE LOW-FREQUENCY ELECTRICAL STIMULATION IN SUBJECTS WITH DIFFERENT FORCE GENERATING CAPACITY

Papaiordanidou, M., Guiraud, D., Varray, A.
University of Montpellier I, UFR STAPS, France

Fatigue induced by neuromuscular electrical stimulation (NMES) is poorly understood. Furthermore, although recent researches give evidence for implication of different sites along the pathway of force production, the muscle factors susceptible to influence the response to electrically induced fatigue are still unknown. The purpose of the present study, therefore, was to identify the time course of neuromuscular changes during NMES according to muscle’s capacity to generate force.

Twelve healthy subjects with different force generating capacities (7 Strong (S) with mean torque during Maximal Voluntary Contraction (MVC) 88.8±1.6Nm and 5 Weak (W) with mean torque 64.4±3.2Nm) participated in an electrostimulation protocol for the triceps surae, composed of 3 series of 17 stimulation trains [4s ON - 6s OFF, pulse duration 450µs, frequency 30Hz, at maximal tolerated intensity]. Neuromuscular tests were performed before, during and immediately after the protocol. Torque and EMG activity of the gastrocnemius medialis muscle were continuously recorded. Alterations in muscle’s characteristics (excitability and contractile properties) were evaluated by analysis of the muscle compound action potential (M-wave) and twitch torque. Motoneuron excitability was assessed by the H-reflex, expressed in absolute value and normalized to M-wave maximal amplitude (respectively Hmax and H/M). Changes in the central command were assessed by using the twitch interpolation technique and the root mean square (RMS and RMS/M) obtained during MVC. MVC significantly decreased from the first 17-train bout and throughout the protocol for both groups (from 88.8±1.6Nm vs 64.4±3.2Nm at pre to 78.8±3.3Nm vs 58.2±2.7 at post51, for S and W respectively), giving evidence of precocious neuromuscular impairments. Motoneuron excitability was not affected (no change of Hmax and H/M). Muscle contractile properties were significantly potentiated at post17 and for the rest of the protocol (H2±e14% for S vs 37±e6% for W for Pt values at post51 for both groups. Muscle excitability was significantly altered only in S, as proved by the significant decrease in M-wave amplitude and muscle response to trains of stimulation (-2.9±3.7% and -13±4.5% for post1 respectively). Level of voluntary activation assessed by the twitch interpolation technique was lower for W and, although RMS/M was significantly decreased for both groups, the decrease in W was significantly more pronounced (-21.8±4.5% vs -14.5±6.2% for S).
Neuromuscular fatigue can be attributed to both central and peripheral mechanisms for the S group, while for W it appears that mainly central mechanisms are involved. These observations should be taken under consideration when seeking to optimise training strategies for people with neurological disorders. The results show that improving muscle strength would not necessary delay neuromuscular fatigue, but changes its nature.

THE EFFECTS OF SKILL TRAINING ON STRETCH REFLEX INSTABILITY

Budini, F., Durbaba, R., Macaluso, A.
Istituto Universitario di Scienze Motorie, Rome, Italy, Northumbria University, Newcastle, UK, Italy

Stretch reflex instability (SRI) is one of the possible mechanisms underlying tremor, either in normal or exaggerated conditions (Durbaba et al., 2005). It has been shown that SRI decreased following isometric strength training in healthy young individuals, along with increased levels of maximal voluntary contraction (MVC, Durbaba et al., 2008). However, the question arose from this study as to whether the reduction in SRI could be partly attributed to following visual feedback on a computer screen, i.e. skill training. Here we investigate the effects of short term skill training, without strength training, on muscle strength and SRI in healthy individuals.

Sixteen individuals (aged 21-29 years), with no known history of neurological disorder, took part in the study. Local Ethical Committee approval was obtained for the study and subjects gave written, informed consent. With subjects seated comfortably, force of contraction from knee extensors of the dominant leg was recorded using a dynamometer (Kin-Com, Chattanooga, USA) to assess MVC and SRI at baseline and after 4 weeks. Following the baseline recordings, 8 subjects were instructed to continue their levels of activity as normal and acted as controls. The remaining 8 subjects undertook a 4-week skill training programme. This involved subjects attending the laboratory 3 times a week for 25 minutes of visual feedback exercise (12 sets, 10 repetitions each (5s contraction, 3s rest), between 6% and 8% of MVC, with a 30s interval between each set). Stretch reflex instability was induced during anisometric contractions at 30% baseline MVC, with 2 spring loading resistances that preferentially activated the long or short latency components of the stretch reflex (long=5.35 N mm⁻1, short=11.06 N mm⁻1). The anisometric contractions were analysed to compute autospectra of force fluctuations.

For both the training and control subjects, MVC did not significantly change (1.0% and 1.1% increase, respectively). Skill trained individuals showed a significant reduction in the amplitude of force fluctuations in anisometric contractions against the long spring (-106.0±10.9 µm, compared to +28.5±42.0 µm in the controls; P<0.01). There was no significant decrease in force fluctuations when anisometric contractions were initiated by the short spring (-99.4±41.5 µm, compared to +14.5±31.2 µm in the controls). The results indicate that the skill training only protocol may reduce tremor by reducing the long-latency SRI, and could be a useful rehabilitation tool in individuals with exaggerated forms of tremor.

DIFFERENCES IN RATE OF FORCE DEVELOPMENT AND NEURAL ACTIVATION BETWEEN ELITE EXPLOSIVE POWER ATHLETES AND CONTROLS

Tillin, N., Jimenez-Reyes, P., Poin, M., Folland, J.
Loughborough University, United Kingdom

There is evidence of a relationship between muscular rate of force development (RFD) and neural activation (De Ruiter et al., 2004), and therefore it might be expected that explosive power athletes have a greater RFD than non-athletes due to enhanced neural activation, but this has not yet been investigated. The present study compared differences in RFD, neural activation, and electromechanical delay (EMD) between elite explosive power athletes (ATH; n = 9) and aged-matched controls (CON; n = 10). During 3 separate trials (each separated by 1 week) participants sat in a custom built isometric rig (hip and knee angle 90° and 80° respectively), and completed a series of involuntary and voluntary isometric contractions of the knee extensors of their dominant leg. Force was measured from a strain gauge, sampled at 2000 Hz, and electromyography (EMG) was recorded from the rectus femoris (RF), vastus lateralis (VL), and vastus medialis (VM). The maximum M-wave of each muscle was established by supramaximal stimulation of the femoral nerve with single pulse (100 µs) twitch contractions. Maximum voluntary force (MVF) and root mean squared (RMS) of the EMG signal at MVF (RMSmax) was established from four 3-isometric maximum voluntary contractions (IMVC), each separated by 30 s. To assess RFD parameters participants performed 10 explosive IMVC (the instruction was to push as fast and hard as possible for 1-2 s), separated by 20 s. The three contractions with the highest peak RFD (RFDp) were analysed to establish average RFD from 0-40 ms (RFD40) and 0-100 ms (RFD100), and each of these variables was normalised to MVF. The RMS of the EMG signal was analysed in three consecutive 50-ms time windows (0-50, 50-100, and 100-150 ms), commencing from EMG signal onset, and was normalised to both maximum M-wave (RMS:M) and RMSmax (RMS:RMSmax). Maximum EMD (EMDmax) was classified as the longest EMD of the 3 knee extensor muscles. A mean of the second and third trials was used for analysis. The ATH had a greater MVF than CON (+28%, P<0.01). The ATH also had a greater RFD40, RFD100, and RFDp (+145%, +39%, and +48%, respectively; P<0.01), however, when these variables were normalised to MVF only RFD40 remained greater in ATH (3.4 ± 1.2 vs. 1.6 ± 0.9 MVFs⁻1; P<0.01). During the 0-50 ms window the ATH had a greater RMS:M ratio in all muscles, and a greater RMS:RMSmax ratio in the RF and VL (P<0.05). There was also a trend for CON to record a longer EMDmax than the ATH (19.1 ± 4.3 and 15.9 ± 2.8 ms, respectively; P = 0.08). The results of this study suggest there may be a difference in EMD between ATH and CON. A greater normalised RFD40 in ATH was found and appeared to be due to a greater neural activation during the initial phase of the contraction. Conversely, any difference in absolute RFD during the later phases of the contraction appeared to be due to the greater strength of the ATH.

SPINAL REFLEXES AND NEUROMUSCULAR FUNCTION IN RESPONSE TO SUBMAXIMAL FATIGUING CONTRACTION DURING SEVERE HYPOXIA

Rupp, T., Racinais, S., Perry, S.
University of Montpellier I, LUR STAPS, France

During submaximal contractions, a progressive central contribution to fatigue may occur before the moment of task failure, suggesting that exhaustion is linked, at least in part, to a decline in muscle activation i.e., motivation, motor cortex capacity to adequately drive the
ASSESSMENT OF NEUROMUSCULAR FATIGUE COMPONENTS DURING A HIGH-INTENSITY TENNIS BOUT

Morana, C., Perrey, S., Varray, A.
University of Montpellier | UFR STAPS, France

Introduction: Tennis is characterised by repetitions of fast starts, stops and changes of direction during brief periods of exercise at maximal or near maximal intensity, followed by rest periods. These repeated muscle actions on lower limbs induce processes resulting in neuromuscular fatigue. The latter may in turn affect speed and accuracy of movements during a tennis match. The aim of this study was to assess acute neuromuscular fatigue and its components in knee-extensor muscles during a high-intensity tennis bout as seen in typical tournament.

Methods: 9 well-trained male tennis players of national level (mean ± SD: 21.2 ± 1.7 yr; mass: 77.6 ± 8.9 kg; body fat: 12.1 ± 3.0%) performed a standardized tennis bout representative of the degree of intensity occurring during a match. Neuromuscular tests were performed before and immediately after each of the 4 intermittent 8-min heavy exercises proposed (closed situations with basket feed-throughout recovery in hypoxia but not in normoxia. The MVIC force recovery profile was associated with a progressive restoration of the group III and IV muscle afferents. Finally, our results put forward the major role of supraspinal and spinal mechanisms in limiting to the same extent endurance time during submaximal contraction in normoxia and hypoxia.

Discussion/Conclusions: The high-intensity tennis bout resulted in a significant neuromuscular fatigue observed from the third out of four contractile dysfunction. Both the neuromuscular tests and the proposed 4 intermittent exercises may be used regularly to track the physiological training-induced changes in tennis players over the season.
The healthy subjects showed concomitant increases in muscle activity with both ATF muscle length estimates. This within-step modulation is likely to stem from proprioceptive afferents, as no modulation was seen in the deafferented subject’s activation pattern.

**THE EFFECT OF CARBOHYDRATE INGESTION ON THE INTERLEUKIN-6 RESPONSE TO A 90-MINUTE RUN TIME-TRIAL**

Ansley, L., Barwood, M., Eglin, C., Robson-Ansley, P.
Northumbria University, United Kingdom

Cytokines released during exercise have been implicated in suppressing the immune system [1,2] and mediating fatigue [3]. Carbohydrate (CHO) ingestion during constant load exercise is associated with an attenuated interleukin-6 (IL-6) response immediately post-exercise [1,2], although, during intermittent high intensity exercise [4] and self-paced running [5,6] the effect of CHO ingestion on immediate post-exercise IL-6 is equivocal. However, the self-paced studies comprise field studies and as such factors known to affect IL-6 release (e.g. intensity) were not accounted. Therefore the aim of this study was to evaluate the effect of CHO ingestion during a laboratory-controlled self-paced time-trial on post exercise IL-6 concentration. Seven recreationally trained runners completed two 90-minute time trials ingesting either CHO or a placebo, in a randomized order. The study was of a double-blinded, placebo-controlled, cross-over study design. Immediate post-exercise IL-6 levels were significantly lower in the CHO trial compared with the placebo trial (5.3(1.9) pg/ml vs. 6.6(3.0) pg/ml, respectively, p=0.029). Furthermore, distance covered in 90 minutes was significantly greater with CHO compared to placebo ingestion (19.1(1.7) km vs. 18.3(1.9) km, respectively, p=0.002). Blood glucose was maintained during both conditions. The results from this study support the model in which IL-6 release during exercise is attenuated by CHO ingestion. Furthermore, the full extent of the mediating effect of CHO is probably masked by the increased intensity at which the CHO trial was performed. However, improvement in time to performance is unlikely to be explained by the physiologically insignificant difference in post-exercise IL-6 between trials. The confounding effect of intensity in self-paced exercise trials examining IL-6 illustrates the need to use a different model to assess the role of IL-6 in mediating fatigue. In conclusion, CHO intake attenuates the immediate post-exercise IL-6 response in a 90-minute running time-trial.

**PROTECTIVE EFFECT OF EXERCISE ON STRESS-INDUCED IMPAIRMENT OF SPATIAL MEMORY IS DEPENDENT ON IGF-1**

Toshio, M., Nakajima, S.
Nippon Medical School, Japan

Introduction.
Habitual exercise improves learning and memory in mice and rats. Improvement of learning and memory is closely related to neurogenesis in hippocampus and dependent on uptake of blood insulin-like growth factor 1 (IGF-1) into brain. On the other hand, chronic stress impaired learning and memory of the animals and is related to neurogenesis in hippocampus. Therefore, purpose of this study was to investigate whether exercise might protect stress-induced impairment of learning and memory and protective effect of exercise might be dependent on IGF-1.

Methods.
Male C57BL/6 mice aged 2 weeks old were randomly divided into four groups: control mice, restraint-stressed mice (RS mice), exercised mice (Ex mice) and JB1-administrated mice (JB1 mice). Control mice were fed in a standard mice cage (width 32 cm, length 21.5 cm, height 10.5 cm). In this case, four mice were fed in a cage. RS, Ex and JB1 mice were fed in a six-divided cage to make physical activity of mice small. In the six-divided cage, the living space per a mouse was 10 cm wide, 10 cm long, and 10.5 cm tall. In JB1 mice, osmotic pump contained JB1, antagonist for IGF-1 receptor, was implanted into their back, while osmotic pumps contained saline was implanted in control, RS and Ex mice. RS, Ex and JB1 mice were exposed to 8 h of immobilization daily. In addition, Ex and JB1 mice were performed 1 hour of treadmill running daily. Four weeks later, spatial learning was measured by water maze test. After water maze test, brains of mice were removed under anesthetization, cut into slices and used for immunohistochemical analysis of Ki67-positive cells in the granule cell layer (GCL) of the hippocampal dentate gyrus.

Results and Discussion.
RS mice showed significant impaired spatial memory and suppression of Ki67-positive cells in GCL of the hippocampal dentate gyrus compared with control mice. Though Ex mice were exposed to 8 h of immobilization daily as same as RS mice, Ex mice did not show impaired spatial memory and suppression of Ki67-positive cells. On the other hand, JB1 mice showed significant impaired spatial memory and suppression of Ki67-positive cells as same as RS mice in spite of 1 h of treadmill running daily. These findings suggested that chronic stress induced by daily immobilization and restriction of physical activity impaired spatial memory and neurogenesis in hippocampus. Exercise prevented the impairment of spatial memory and suppression of neurogenesis, while JB1 canceled protective effect of exercise. Therefore, protective effects of exercise on stress-induced impairment of spatial memory and neurogenesis might be dependent on IGF-1.

DECREASED IRS-1 (SER 307) PHOSPHORYLATION IS ASSOCIATED WITH HEIGHTENED INSULIN SENSITIVITY FOLLOWING SHORT TERM ENDURANCE TRAINING

Venables, M., Hulston, C., Aldred, S., Mann, C., Jeukendrup, A.
The University of Birmingham, United Kingdom

Introduction: Insulin receptor substrate-1 (IRS-1) is an important protein involved in insulin signal transduction and can undergo post-translational modulation on many serine/threonine residues. IRS-1 serine 307 (ser307) has been identified as one such residue that once phosphorylated can prevent the interaction with the insulin receptor and therefore inhibit downstream insulin signalling events. We hypothesize that a reduction in IRS-1 (ser307) phosphorylation is one of the many mechanistic alterations that can result in improvements in insulin sensitivity following exercise training in obese men.

Methods: Seven sedentary obese, but otherwise healthy male participants (Age, 40 ± 7 y; BMI, 34.2 ± 1.7; VO2max, 35.5 ± 5.9 mL/kg/min) were recruited for the purposes of this study. Endurance exercise training at a predetermined intensity eliciting maximal fat oxidation was performed five times per week for four weeks. During the week preceding exercise training and 72 hrs following the final exercise bout, a muscle biopsy, OGTT, VO2max test and measurements of body composition were undertaken. IRS-1 (ser307) in human skeletal muscle was measured using western blot following immuno-precipitation. Diet was controlled the day before all trials (50% carbohydrate, 35% fat and 15% protein, ~2900 kcal/day). Variables were compared using paired students t-tests.

Results: On average exercise training intensity was 48 ± 6 %VO2max, with an average heart rate of 112 ± 4 bpm. Maximal oxygen uptake was significantly increased following exercise training (34.8 ± 6.2 mL/kg/min and 36.4 ± 5.5 mL/kg/min, pre and post training respectively) or body composition (32.6 ± 4.2 and 32.4 ± 3.5 % body fat pre and post training respectively).

Conclusion: Four weeks of low intensity endurance exercise training reduces IRS-1 (ser307) phosphorylation and increases insulin sensitivity in sedentary obese men.

UPPER RESPIRATORY TRACT INFECTIONS AND NAIVE AND MEMORY T CELL SUBSETS ALTERATIONS IN SWIMMERS DURING A TRAINING SEASON

Teixeira, A., Rama, L., Azevedo, S., Rosado, F., Alves, F., Paiva, A.
Faculty of Sport Sciences and Physical Education, University of Coimbra, Portugal

Objectives
Very few studies have looked at changes in lymphocyte recirculation after exercise and even fewer have looked at the chronic effects during a training season. The aim of this study was to study how training load might influence the proportion of circulating naive and memory T cells subsets in peripheral blood (PB) of high competitive levels athletes and how it could affect susceptibility to disease.

Methods
To study the response of naïve and memory T cell subsets, quantification, by flow cytometry, of PB cells from 19 well trained swimmers (13 men and 6 women, mean age 17±1.25 years old, was done in four different moments of the training season that matched the transitions between preparation cycles. The CD4, CD8 and G/D T cells expressing the naïve (TN), central memory (TCM), effector memory (TEM) and effector (TEFF) T cells compartments were determined by CD45RA and CCR7 expression (I). The upper respiratory tract infection (URTI) episodes that occurred during the training season were registered using daily logs. Training load and participation on competition events were also monitored.

Results
An increase in CD8+ memory effector cells (CCR7-CD45RA-) and a decrease in the CD4+ memory effector T cells (CCR7-CD45RA+) were found between the first and second moment of the training season. G/D T cells also increased their memory effector cells and decreased their terminal effector cells (CCR7-CD45RA-) from the pre-season to the 2nd evaluation. An increase in naïve CD4+ and CD8+ T cells (CCR7+CD45RA+) between the 1st and 2nd moments of evaluation also occurred but with no statistical significance (P=0.1 and P=0.62 respectively). Furthermore, athletes that suffered more infectious episodes appear to show a higher number of CD8+ and CD4+ effector T cells compared to those athletes that had less than 3 URTIs during the training season.

Discussion
An increase in training load volume seems to induce a change in the basal number TME and TEFF cells that are CCR7- and cannot efficiently recirculate through the lymph nodes and Peyer’s patches but migrate to peripheral and non-lymphoid tissues were they can exert their citotoxic activity. An increase in the number of lymphocytes in the lung has been described after exercise (2) which might be an adaptation to increased ventilation during exercise. The redistribution of effector lymphocytes into target organs may represent an increase in immune surveillance in organs that serve as major defence barriers of the body. The higher number of effector cells in those athletes with more than 3 URTI may reflect the response of to an invasive agent.

This preliminary data seem to indicate that quantitative and qualitative alterations observed in T cell subsets may be related to the participation of athletes on specially intensive and voluminous training programs and their susceptibility to infections.

ELECTRICAL STIMULATION SENSORY THRESHOLD IS RELATED TO SUBCUTANEOUS FAT THICKNESS

Mattileutti, N., Morelli, A., Sartorio, A., Duclay, J., Billot, M., Martin, A.
Schulthess Clinic, Zurich, Switzerland

We recently demonstrated lowered electrical sensory thresholds in women than in men (1), i.e., female subjects perceived electrical stimulation with lower current amplitudes than their male counterparts [-43%]. Interestingly, the lowest sensory currents were observed in those subjects with the largest skinfold thicknesses (women), therefore suggesting a link between subcutaneous adipose tissue mass and sensory excitability. To confirm these observations, we compared detection-threshold stimulation levels between men and women having wide ranges of subcutaneous fat i.e., obese individuals. Moreover, since skinfold thickness does not provide an accurate assessment of the quantity of subcutaneous fat, we quantified thigh subcutaneous fat thickness using B-mode ultrasound (2), and attempted to relate this parameter to sensory threshold.

Thirty adult obese individuals (15 men and 15 women, BMI 41.6 ± 42.8 kg/m², respectively) were enrolled in this study. B-mode ultrasound images were obtained from the lateral aspect of the vastus lateralis muscle at half of femur length, while the subject was
seated with an angle of 90° at the hip and knee joints. In the same position, the quadriceps femoris muscle was stimulated at 50 Hz with a portable electrical stimulation unit and two surface electrodes. Electrodes were placed 5 cm below the femoral triangle and at half of femur length, over the vastus lateralis muscle belly. The investigator progressively increased current amplitude (mA) from zero to sensory threshold, i.e., when the subject indicated lowest perception of stimulus sensation. Subcutaneous fat thickness and sensory thresholds were measured during stimulation of 300 ms (±15%) for KE in women (24.4±7.0 mm) and in men (12.7±3.6 mm). Sensory threshold was significantly lower in women (23.3±0.75 mA) than in men (38.0±0.70 mA). The lowest sensory thresholds were observed in those subjects with the largest fat thicknesses and vice versa. p<0.001, fat thickness=0.58×sensory threshold+3.62.

In line with our previous investigation, the present findings allow us to speculate that the number and/or sensitivity of cutaneous and subcutaneous receptors activated by detection-threshold current could differ between men and women, both obese (this study) and nonobese (1). Considering that the low electrical stimulation levels would predominantly activate large-diameter A-beta afferents, sex differences could exist in the properties of encapsulated nerve endings (such as Pacinian corpuscles and Merkel disks). The choice of optimal current amplitude is paramount to the effectiveness of electrical stimulation treatments (e.g., for TENS). We therefore recommend that practitioners consider that women may present lower sensory thresholds than men.

SIMULATED ALTITUDE DURING THE NIGHT AMELIORATES SYMPTOMS OF ACUTE MOUNTAIN SICKNESS
Boehm, A., Menold, E., Grigoriev, I., Bärtsch, P., Dehnert, C.
Medical Clinic, University Hospital, Germany

Acute mountain sickness (AMS) occurs after rapid ascent to high altitude in otherwise healthy mountaineers. The risk of AMS is influenced by individual susceptibility, absolute altitude, rate of ascent and preacclimatisation. All these risk factors have been shown to be approximately the same weight. Since individual susceptibility and absolute altitude and in most cases also rate of ascent are given for a particular expedition or trekking tour, preacclimatisation is the only preventive factor that can be influenced individually. Thus we hypothesised that regular exposure to normobaric hypoxia during the night leads to ventilatory acclimatisation and reduces incidence and severity of AMS.

To test this hypothesis 75 healthy men at the age between 18 and 55 years were included in a randomized double blinded study. For preexamination subjects were exposed for 4 h at a FiO2 of 12% (approx. 4500m). Before and at the end of this exposure AMS (Lake Louise (LL)-score, AMCS-sc, ventilation and blood gases were assessed. Then an acclimatisation period of 14 nights in commercially available “hypoxia-tents” followed. Hypoxia (HYP) and control (CON) group received visually identical equipment which was technically adapted to the assigned group. Handling of the equipment was the same in both groups. All subjects were advised to set the level of hypoxia to a FiO2 of 15.4% (approx. 2500m) in the first night, then gradually decrease FiO2 each night by 0.2% until the final “altitude” of 33.08% (FiO2=14.0%) was reached. This altitude was then sustained until the 14th night. After a break of 4 days subjects were examined during one day (20 h, 3:00 p.m. – 11.00 a.m.) at FiO2 of 12%. Again AMS, ventilation and blood gases were assessed before, after 4 and after 20 h of hypoxia.

For technical reason most subjects did not reach the desired sleeping altitude of 3043m at average. We therefore analysed the 21 “highest” (=HYP) and the 21 “lowest” (=CON) according to the performed power analysis. Mean sleeping altitude in HYP was 2599m compared to 2355m in CON. Both, LL- and AMCS-score were significantly reduced by sleeping in hypoxia (LL: 3.1±2.2 vs. 5.6±3.6, p=0.039, AMCS-c: 0.38±0.38 vs. 1.10±1.23, p=0.014). The incidence of AMS was 29% in HYP compared to 57% in CON, which was not significant (Chi²-test p=0.119). Blood gas and ventilatory parameters showed no significant difference between HYP and CON. Sleepquality during the acclimatisation period in the tents was not affected by hypoxia.

The results of the study indicate that preacclimatisation during 14 nights in normobaric hypoxia reduces symptoms of AMS and therefore is useful to prevent AMS if acclimatisation in natural altitude is not possible. The effects can be expected to be even more pronounced if a higher degree of hypoxia be can be attained in the tent.

HOW FATIGUED ARE WE AFTER A 24 H RUN?
Millet, G., Martin, V., Kerhervé, H., Messonnier, L., Banfi, J., Geyssant, A., Féasson, L.
Jean Monnet University, Saint-Etienne, France

Introduction. Neuromuscular fatigue after ultra-endurance exercises (> 4h) has been mostly studied during real competition (e.g. Millet et al. J Appl Physiol 92(2): 486-492, 2002) so that only pre-post measurements are generally performed. In addition, despite an increasing number of people participating in 24h races, such extreme fatigue has rarely been investigated. The aim of this study was to examine the causes and the kinetics of neuromuscular fatigue induced by a 24h run.

Methods. Neuromuscular function evaluation (NMFE) was performed before, every 4 h during and after a 24h treadmill run in 12 experienced ultramarathon runners. NMFE was conducted in determined extensors (KE) and flexors (PF) with maximal voluntary contractions (MVC, global fatigue), KE and PF maximal voluntary activation (%AV; central fatigue), vastus lateralis and soleus M-wave (sarcolemmal excitation), KE and PF low and high frequency stimulation (excitation-contraction coupling), and KE absolute force of MVC + 0.3 s superimposed tetanus at 100 Hz (intrinsic fatigue). Blood samples were taken immediately after each NMFE.

Results. The subjects ran an average of 18.65±0.68 h on the treadmill, which equated to 149.2±15.7 km at an average intensity of 39.4±4% of their velocity associated with VO2max. KE strength losses were greatest during the first 12h (−32%), KE MVC decreased 41±17% (P<0.001) at Post 24h. PF MVC decreased linearly to its lowest value -34±16% (P<0.001) after 20h. %AV decreased by 33±22% (P<0.001) and 15±19% (P<0.011) for KE and PF, respectively. M-wave alterations were only observed for soleus. Low-to-high frequency ratio remained unchanged in both muscle groups. Intrinsic KE force decreased to a low extent (-10%, mostly during the first 16h) and a large variability was found for this factor (±16%). This large variability was also observed for serum creatine kinase concentrations (±16%).

Conclusion. Large strength losses were observed in both plantar flexor and knee extensor muscles. Fatigue after the ultra-endurance running event was mostly attributable to central mechanisms for all the subjects, especially for KE. On the contrary, a large heterogeneity was found between subjects for markers of muscle damage. Intrinsic fatigue showed a plateau after 16h and no low-frequency fatigue was observed, in line with previous reports on prolonged but not extreme exercises (Millet and Lepers, Sports Med 34(2): 105-116, 2005).
2004, suggesting that excitation-contraction coupling does not play a role in fatigue induced by an ultramarathon. Finally, the alteration of sarcolemmal excitability seems to be dependant on the muscle group.

**TYPE II MUSCLE FIBER HYPERTROPHY AFTER RESISTANCE TRAINING IS ACCOMPANIED BY A FIBER TYPE-SPECIFIC INCREASE IN SC CONTENT IN ELDERLY MEN**

Verdijk, L., Gleeson, B., Jonkers, R., Meijer, K., Savelberg, H., Dendale, P., Van Loon, L.
Maastricht University, Netherlands

Satellite cells (SC), or muscle stem cells, are the only known source for the generation of new myonuclei in skeletal muscle tissue. SC normally lie quiescent between the basal lamina and plasma membrane of muscle fibers. Upon activation, SC can proliferate and differentiate into normal myonuclei that fuse with existing myofibers. As such, SC are essential for myofiber repair, maintenance and growth. We recently reported that muscle fiber type-specific atrophy, which is characteristic for age related loss of muscle mass, is accompanied by a reduction in type II muscle fiber SC content (Verdijk, 2007). In the present study, we aimed to determine whether muscle fiber type-specific hypertrophy following resistance type exercise training (RT) in the elderly is associated with changes in SC content. A total of 13 healthy elderly men (65-85y) participated in a 12 week RT program for the lower extremities. Muscle strength for leg extension and leg press exercise was determined before and after the intervention program. In addition, body composition (DEXA and CT) was assessed, and muscle biopsy samples were collected before and after intervention. Immunohistochemical procedures for MHc- and CDS6-staining were used to determine fiber-specific changes in muscle fiber area and SC content in skeletal muscle tissue. One-repetition maximum strength for leg press and leg extension increased 25-30% after training (P<0.001). Leg lean mass increased from 18.3±0.5 to 19.3±0.5 kg, and quadriceps cross-sectional area increased from 75.9±3.7 to 82.4±3.9 cm² following intervention (P<0.001). At baseline, type II muscle fiber area was smaller than type I fiber area, and myonuclear number was smaller in the type II vs type I fibers. In addition, SC content was significantly lower in the type II vs type I fibers (0.048±0.003 vs 0.089±0.006 SC/fiber, respectively; P<0.001). In contrast to type I muscle fiber area, type II fiber area increased from 5438±319 to 6982±503 µm² following 12 weeks RT (P<0.001). The latter was accompanied by an increase in type II muscle fiber SC content (from 0.048±0.003 to 0.084±0.008 SC/fiber, P<0.001), whereas no changes were observed in type I muscle fiber SC content. Muscle fiber type specific differences in size, myonuclear number, and SC content observed prior to intervention had entirely disappeared after intervention. We conclude that type II muscle fiber atrophy in the elderly can be reversed by resistance type exercise training. This study is the first to show that fiber type-specific hypertrophy is accompanied by the specific increase in type II muscle fiber SC content in the elderly.

**POSITIVE EFFECTS OF COLD WATER IMMERSION AND ACTIVE RECOVERY ON SUBSEQUENT MAXIMAL CLIMBING PERFORMANCE IN FEMALE CLIMBERS**

De Geus, B., Heyman, E., Mertens, I., Meueusen, R.
Vrije Universiteit Brussel, Belgium

Introduction Rock-climbing is becoming more and more popular and the number of climbing competitors is increasing every year (Mermier 1997, Sheel, 2004). Climbing competitions often require subsequent climbs (Watts et al. 2000). While the effects of active versus passive recovery on lactate removal after climbing have been studied, the impact on subsequent climbing performance remains unknown (Watts 2000, Draper 2006). Moreover, no other modalities of recovery have been tested to increase performance. Therefore the aim of this study was to investigate the influence of passive, active (cycling), electromyostimulation and cold water immersion (CWI) on subsequent maximal climbing performance.

Material & Methods Thirteen trained female climbers (12.7 +/-. 8.9 years, indoor-climbing level on overhanging wall from 6b to 7b+, French grading system), VO2max: 47.5 +/- 5.3 mL/min/kg, came to the climbing centre on four occasions separated by one week. On each occasion, they had to perform two climbing tests (C1 and C2) until volitional exhaustion on a pre-practised route (overhanging wall, level 6b), between which they recovered for 20 minutes. Four recovery methods were used in randomised order: passive recovery, active recovery on electricity braked cycle ergometer at 30-40 W, electromyostimulation on the forearm muscles (bimetric TENS current, decreasing from 9Hz to 2 Hz) or CWI of the forearms and arms (three periods of 5 min at 15 +/- 1 °C). The effects of recovery methods on performance (number of movements and climb duration and distance) at C2 and physiological parameters during the 20-min recovery (blood lactate, heart rate, skin temperatures) were assessed with two-factors repeated measures ANOVA.

Results Using active recovery and CWI, performance at C2 was maintained in comparison with C1 performance (recovery method-by-climb interaction, P < 0.05), whereas C2 performance was impaired compared to C1 (P < 0.01) using electromyostimulation and passive recovery. Lactate decreased during recovery with the four methods. The greatest decrease occurred with active recovery with lactate levels achieving the lowest concentrations (at 10 and 20 min of recovery) (P < 0.05) (time-by-recovery method interaction, P < 0.001). Skin temperatures of arms and forearms, but not chest and shoulders, were lower throughout the CWI recovery compared to the other three methods (P < 0.001).

Conclusion Active recovery and CWI are two means of preserving performance when repeating acute exhausting climbing trails in female climbers. The positive effects may partly depend on a greater lactate removal and on possible decreases of subcutaneous tissues temperatures, for the active and immersion methods, respectively.

THE POTENTIAL OF WHOLE BODY VIBRATION TRAINING TO INTEGRATIVELY COUNTERACT THE EFFECTS OF 14-DAYS OF IMMOBILIZATION

Liphardt, AM., Boecker, N., Mündermann, A., Koo, S., Andriacchi, T., Zange, J., Kleinoeder, H., Mester, J., Heer, M.
Department of Sports Medicine & Biology of Physical Activity, Faculty of Physical Education and Sports Science, Greece

Mechanical stimulation is essential for the homeostasis of the musculo-skeletal system. In microgravity the human body responds with deconditioning to the lack of mechanical loading. On earth these effects can be simulated with immobilization at 6°-head-down-tilt bed rest (HDT). In the 'Vibration Bed Rest Study' (VBR-Study) we hypothesized that whole body vibration training will change the response of the body to HDT with focus on balance, skeletal muscle performance, and knee cartilage. Vibration training seems to be a promising method because of beneficial effects that have been found in previous training studies. We investigated the combined effect of HDT and vibration training (twice per day; 5 x 1 Minute; 20 Hz) on muscle strength, balance performance, and cartilage morphology. 8 male healthy subjects performed two phases of 14-days of HDT in a randomised cross-over design. The experiments were scheduled before and after the HDT period. Blood was drawn at predefined times during the study. HDT lead to a significant decrease in maximal power of the knee extensors which could be prevented by vibration training. Maximal power of the knee flexors was not affected by HDT. Isometric force did not change due to HDT for the knee flexors and knee extensors. The results indicated that changes in isometric force and power after 14 days of HDT were muscle and subject specific and may have been influenced by their initial physical status. In reference to the power of the knee extensors, the used training protocol was sufficient to cause a significant difference in the response to HDT. The analysis of balance performance was done with the Posturomed device, using the parameters ‘holding time’ and ‘displacement’. HDT did not lead to deterioration in both parameters, whereas vibration training lead to a significant decline in the balance performance level. Decreases in cartilage thickness after bed rest were observed for the tibial condyle using magnet resonance imaging of the right knee. The effects inverted into an increase with vibration training. No changes were observed for the femoral condyle. After 24h of HDT, blood serum concentrations of ‘Cartilage oligomeric matrix protein’ (COMP) decreased significantly and the values returned to baseline after bed rest. Vibration training did not alter this effect. Summarizing the results, the degenerative effects of HDT were not to the degree that was previously expected. This may be the effect of the well controlled study conditions, the normo-caloric diet, the length of the training intervention and the allowance to walk to the training room twice daily. As the deconditioning was missing in some parts, the training intensity may not have been appropriate to impact the HDT effects. Generally, higher training intensities in the scope of bed rest studies are recommended, in addition to an individually tailored vibration training protocol for each subject with a progressively increasing training intensity.

INFLUENCE OF INGESTING A CARBOHYDRATE-ELECTROLYTE DRINK BEFORE AND DURING 1 H RUNNING PERFORMANCE

Rolla, I., Williams, C., Nute, M.
Loughborough University, United Kingdom

The aim of this study was to investigate the influence of carbohydrate (CHO) ingestion before and during a 1 h running performance test. Seven male endurance trained runners completed three 1 h performance runs separated by 1 week. The study used a double blinded placebo (PLA) controlled design. On two occasions runners consumed a placebo (P1, P2) solution, 8ml/kg 30 min prior to 1 h run and 2ml/kg at 15 min intervals thereafter (15, 30 45 min). On a separate occasion runners consumed the same quantity of 6.4% CHO-electrolyte solution (CI). Total distance covered for P1, P2 and C was 1397 ± 1205 m, 1368 ± 1231 m and 14045 ± 1193 m respectively. There was no difference between the two P trials (P>0.05). Distance covered during run C was significantly greater than both P1 and P2 (P<0.05). The ingestion of CHO resulted in a higher blood glucose concentration at the onset of exercise (P<0.05), but was not different compared to P1 or P2 at any other time point. No significant gastrointestinal discomfort was reported. Blood lactate, CHO and lipid oxida- tion were no different in the three runs. In conclusion, the ingestion of a 6.4% CHO-electrolyte solution before and during exercise improved endurance performance in runners compared to the ingestion of colour and taste matched placebo.

CHANGES IN THE POWER VS. PEDAL SPEED RELATIONSHIP DURING REPEATED SPRINTS IN CHILDREN AND ADULTS

Papasprou, A., Maridaki, M., Bogdanis, G.
Department of Sports Medicine & Biology of Physical Activity, Faculty of Physical Education and Sports Science, Greece

Only few studies have examined the effect of fatigue on muscle mechanical characteristics, as these are described by the force vs. velocity relationship. Buttelli et al. (1) reported that fatigue causes a leftward and downward shift of the force vs. velocity relationship, resulting in a decrease in maximal theoretical pedal speed (Vo) and force (Fo). However, there is no information concerning the influence of fatigue on the optimal pedal speed (Vopt), although this parameter may be related with the ability of muscles to generate power. The aim of this study was to examine the changes of power vs. pedal speed relationship during repeated sprints in boys and men, in an attempt to further investigate the causes of fatigue during this type of exercise. Twelve preadolescent boys (age: 11.8±0.2 y, height: 152±2 cm, body mass: 44±2 kg) and 10 men (age: 21.2±0.6 y, height: 177±2 cm, body mass: 74±2 kg), performed 10 sprints separated by 24s of passive recovery on a Monark cycle ergometer, against a load corresponding to 50% of the optimal resistance (Fopt) as determined by a force-velocity test. Instantaneous power was calculated taking into account the changes in kinetic energy of the flywheel (2). Force, pedal speed and power output for each down stroke were used to determine the linear (r²=0.98) force vs. pedal speed and the quadratic (r²=0.95) power vs. pedal speed relationships for each sprint. Optimum pedal speed (Vopt), Vo and Fo for each sprint were then calculated. Test-retest reliability for these indices was examined in a separate experiment (r²=0.92, P<0.01 for all indices). Differences between the two groups were analyzed using two-way ANOVA with repeated measures on one factor. Peak (PPO) and mean power output (MPO) for the first sprint were higher in men than in boys (peak: 1199±31 vs. 460±28 W, mean: 879±22 vs. 356±20 W, mean ± SE, P<0.01), but men exhibited a more than 3-fold higher drop from the first to the 10th sprint in both PPO (36±3 vs. 11±3%, P<0.01) and MPO (33±2 vs. 9±2%, P<0.01). Vopt in men was 126±3 rpm in the first sprint and significantly dropped to 106±2 rpm to the 10th sprint (P<0.01), a drop equal to 15±2%. Boys Vopt in the first sprint (110±2 rpm) was lower than men’s but remained unchanged during the 10 sprints. Higher values in men than in boys were observed for Fo (boys: 8.6±0.5 vs. men: 19.1±0.3 kg and Fo (boys: 207±3, men: 249±5 rpm) in the first sprint. The drop in Fo from sprint 1 to sprint 10 was 25±3% in men and 7±2% in boys (P<0.01). However the drop in Vo was significant only in men (16±2%) but not in boys (3±3%,NS). The main finding of the present study is that repeated sprints on a cycle ergometer cause a...
significant drop in Vopt only in men and not in preadolescent boys. This may be the result of a greater selective fatigue of fast twitch fibers, in men compared with boys.

CONTRIBUTION OF RESPIRATORY MUSCLE BLOOD FLOW TO EXERCISE-INDUCED DIAPHRAGMATIC FATIGUE IN TRAINED CYCLISTS

National and Kapodistrian University of Athens, Greece

We investigated whether the greater degree of exercise-induced diaphragmatic fatigue previously reported in highly-trained athletes in hypoxia (compared to normoxia) (Vogiatzis et al., 2007) could have a contribution from limited respiratory muscle blood flow. Seven trained cyclists (maximal oxygen uptake: 63.7±4.2 ml/kg/min, mean ± S.E.M.) completed in balanced order three 5 min exercise tests leading to different levels of end-exercise arterial oxygen saturation (71.8±2.3, 95.0±0.5 and 99.8±0.1%) via variations in inspired oxygen fraction (0.13%, 0.21% and 1.00%, respectively). Work rates were selected to produce the same tidal volume, breathing frequency and respiratory muscle load at each inspired oxygen fraction (63±1, 78±1 and 87±1% of normoxic maximal work rate, respectively). Cardiac output and leg blood flow were measured by the dye-dilution method. Respiratory muscle blood flow was measured by near-infrared spectroscopy (NIRS) over the left 7th intercostal space using indocyanine green. After hypoxic exercise, twitch transdiaphragmatic pressure fell by 33.3±4.8%, significantly (p < 0.05) more than after normoxic (25.6±3.5% reduction) exercise confirming greater fatigue in hypoxia, hyperoxia produced similar degrees of fatigue (26.6±3.3% reduction) as normoxia. In addition, the mean pressure time product of the diaphragm did not differ across the three exercise tests and ranged between 1056±98 and 1226±87 cmH2O/s/min. Furthermore, arterial lactate concentration did not differ across the three conditions and ranged between 11.5±2.6 (hypoxia) and 9.7±1.6 (normoxia). Despite lower power output in hypoxia, neither cardiac output nor leg blood flow (27.6±1.2 and 15.9±0.9 l/min, respectively) was significantly different compared to normoxia (28.4±1.9 and 17.5±0.9 l/min) and hyperoxia (27.8±1.6 and 14.7±0.4 l/min). Although a substantial cardiac output-leg blood flow difference, >10 l/min, was presumably available for other tissues, respiratory muscle blood flow was surprisingly not different across hypoxia, normoxia and hyperoxia (49.4±11.6, 44.8±7.9 and 37.3±9.3 ml/100ml/min, respectively) and approached in both conditions the level previously reported (Guenette et al., 2008) during resting hyperventilation (50.1±12.5 ml/100ml/min) in these subjects. We conclude that when respiratory muscle load is similar during heavy but submaximal normoxic and hypoxic exercise, respiratory muscle blood flow does not sufficiently increase to effectively lessen the greater diaphragmatic fatigue observed in hypoxia.

COPING WITH STRESS IN SPORT: AN ALTERNATIVE APPROACH

Day, M., Thatcher, J.

University of Chichester, United Kingdom

Lazarus and Folkman (1984) provided an alternative to the stimulus-based sources of stress approach used in stress and coping by proposing that eight properties underlie the stress appraisals of any situation. Their theory stated that for a situation to be appraised as stressful at least one of these eight properties must be present. Thatcher and Day (2008) demonstrated that these properties are evident as antecedent variables of stress in competitive sport. Subsequently, it may also be suggested that an athlete will select coping strategies based on the underlying properties of the situation. This study aimed to examine whether coping strategies are selected to specifically limit the effects of the underlying properties of stress.

Participants were 8 national level, male squash players aged from 18-28 years (M = 23.3yrs, SD ±3.3yrs). For each participant one squash match was filmed for use in a stimulated recall interview. Participants were asked to watch their recorded match and provide a commentary on their thoughts, feelings and actions at the time. Questions were based on a semi-structured guide to gain information on stressful situations and coping responses during the match. Stimulated recall interviews were transcribed verbatim and all dialogue was logged in the context of the point discussed and the actions viewed on the match tape. Themes were then examined deductively and labelled according to their role in the stress process (e.g., underlying property, coping strategy). Data from all participants were combined, similar coping strategies used by participants were grouped together and labelled with a description. Results showed that following the occurrence of a stress appraisal, participants had two potential coping options. First, specific coping strategies were chosen to limit the effects of the particular underlying property. These were focused on reducing the characteristics of that property (e.g., information seeking in ambiguous situations makes the situation less ambiguous). Second, general coping strategies were chosen that were not specific to the underlying property but which lowered stress overall (e.g., self-talk in ambiguous situations is not aimed specifically at making the situation less ambiguous but may help the individual to perceive the situation more positively and thus reduce stress). Consequently, once a stress appraisal had been made participants coped either by reducing the effects of the underlying property or by employing a general strategy to lower overall stress or by combining the two strategies. The results from participants in this study indicate that it is not the situation itself that leads to the choice of coping strategy but the underlying property of the situation.

CURRENT INSIGHTS INTO THE VISUAL BASIS OF BASKETBALL SHOOTING

DeOliveira, R., Oudejans, R., Beek, P.
Faculty of Human Movement Sciences AND German Sports University; Department Research Institute MOVE AND Institute of Psychology, Netherlands AND Germany

In the present contribution, we review our current understanding of the visual control and optical basis of basketball shooting. Previous research on the visual control of basketball shooting suggested that eye and head stabilization relative to the target were crucial for successful performance[1]. It was also established that although visual acuity had not proven a necessary asset[2], experts maintained a long fixation on the target before initiating the free throw[3]. This was interpreted as evidence that movement was pre-programmed during fixation and subsequently executed in an open-loop fashion. However, critics charged that these interpretations were invalid in more dynamic instances, namely in jump shooting, or when the style used allowed vision of the target during movement execution. In support of this assertion, it was demonstrated that seeing the target only during the final shooting movements provided enough information for accurate shooting[4]. We further examined the gaze behaviour of expert basketball players taking free throws and jump shots[5].

It appeared that low-style players looked at the target longer in the free throw than in the jump shot but maintained their performance in both conditions, whereas high-style players always looked at the target during the final shooting movements. In another study we found that introducing visual delays between viewing the target and shooting not only affected performance but also the coupling between adjacent joints of the shooting arm. Both these studies indicated that basketball shooting is controlled online by vision. Thus, to examine whether there was a preferred timing of optical information pick-up, we asked expert players to take jump shots under intermittent viewing. As expected, players preferred to see the target as late as possible, as permitted by the employed shooting style. Having established that basketball shooting is controlled online and that players rely on the latest and most updated information about the target, we investigated what information sources underlie this perceptual-motor task. In a series of experiments it was shown that players use the angle of elevation as they direct eyes and head to the target, and that the use of this information source is calibrated to the height of the basket.

THE EFFECT OF INCREASING CONTEXTUAL INTERFERENCE ON THE PRACTISING OF A MOTOR SKILL

Horner, K., Fitzpatrick, K., Smyth, P.
University of Limerick, Ireland

The Contextual interference (CI) effect refers to the learning benefits that result from practising a number of skills in a random (RA) or serial (S) format rather than in a blocked (BL) format, whereby practice on one skill is completed before practising on the next. The CI effect has been demonstrated with both novice (Goode & Magill, 1986) and experienced (Hall et al., 1994) performers. Porter & Magill (2004) found trends that novice putters in golf might benefit most from an increasing CI (ICI) practice schedule, involving a progression from BL to S to RA practice. The purpose of this study was to test the ICI schedule with experienced putters.

Participants (n= 21) with a minimum of 2 years experience, were assigned to an ICI, RA or BL practice group, following a familiarisation session. The study involved a golf putting task at three distances, 1.83m (6ft), 2.44m (8ft) and 3.05m (10ft). A pre-test was undertaken, followed by 54 practice trials, in the order of the practice group to which participants were assigned. For the ICI group, 18 trials in a BL order were followed by 18 trials in a S order and finally 18 trials in a RA order. This was followed by a post test. Retention and transfer tests took place 5 days later. An undulating green were used in the study in order to provide for ecological validity. Outcome measures for performance were total accuracy and total consistency. These were derived from a 95% standard ellipse area calculated, based on the exact final ball position of each putt.

A statistically significant improvement in consistency was found in the ICI and RA groups from pre to retention tests. Trends in results, although not statistically significant between groups, indicated that the BL and ICI groups performed better than the RA group during acquisition, while the ICI group had the greatest accuracy in the transfer test. These findings are similar to those of Porter & Magill (2004) and indicate the potential that one type of practice schedule may have over another in producing performance benefits. Trends in results suggest that it may be possible, using an ICI practice schedule among experienced performers, to reduce acquisition performance decrement usually seen with RA practice, without consequently sacrificing any long term learning benefits. However, this warrants further study. Increasing the number of practice sessions may yield more significant findings. Further study should also consider skill level within those classified as experienced.

A NOVEL MEASURE OF ATtributions, AND MAIN AND INTERACTIVE EFFECTS OF ATtributions UPon SELF-EFFICACY AND PERFORMANCE

Coffee, P., Rees, T.
University of Exeter, United Kingdom

Rees, Ingledew, and Hardy (2005) proposed that attribution research should focus on the main effects of controllability, together with the interactive effects of controllability and generalisability dimensions (stability, globality and universality) upon outcomes such as self-efficacy and performance. Five studies are reported, providing evidence of construct validity for a novel measure of attributions, together with evidence of main and interactive effects for attributions upon self-efficacy and performance.
In study 1, the factor structure of a four-factor 16-item measure of attributions (the CSGU) assessing the dimensions of controllability, stability, globality and universality was confirmed across all successful conditions ranging from a child born in December, though both find themselves in the same age group. Using data from the NHL, Grondin et al. (1984) found a strong over-representation of players born at the beginning of the year and an under-representation of those born late, the former being taller than the latter. Given that height is the most valued physical attribute in youth categories, players born a long time after the cut-off date may be over-represented among dropout athletes.

In conclusion, support was provided for the factor structure of the CSGU, together with evidence of main effects for attributions upon outcomes following more successful performances and interactive effects following less successful performances (and failure). The interactions suggest that where opportunities for self-enhancement are precluded personal self-belief will be compromised and performance will suffer.

MORE THAN THE X FACTOR: CONSIDERING THE ROLE OF PSYCHOLOGICAL CHARACTERISTICS IN TALENT DEVELOPMENT

MacNamara, A., Collings, D.

University of Limerick, Ireland

More than the X factor: Considering the role of psychological characteristics in talent development

Talent is typically conceived as the ability to perform at an elite level, with little consideration given to the capacity that such an individual needed in order to negotiate the pathway to excellence. The importance of psychological factors as determinants of elite performance is already well established in the literature (Gould, Differenbach & Moffett, 2002). However, given the complexities involved in the development of talent, it is pertinent to consider the role that Psychological Characteristics of Developing Excellence (PCDEs) play as ‘determinants of development’. In short, modern talent development approaches are beginning to stress the importance of Psychological Characteristics of Developing Excellence (PCDEs) as the best way to identify, and then realize through systematic development and facilitation an individual’s potential. However, the application of PCDEs may be complicated by differences between both activity-related developmental pathways (e.g. sport and music), and the challenges faced at different stages of development. Therefore, the purposes of this study were firstly to examine whether the same PCDEs shown as important for elite performance facilitate the successful negotiation of the pathway to excellence, and secondly whether PCDEs are deployed differently at different stages of development and within different domains. Twenty four elite participants were purposefully sampled from different performance domains (athletics N = 8, team sports N = 8), and music N = 8). A retrospective, semi structured interview methodology was adopted. Results suggest that the participants employed a range of PCDEs similar to those found at elite level as they negotiated the inevitable challenges and transitions encountered along the pathway to excellence. However, PCDEs were deployed differently depending on the challenges faced by performers at different stages and within different domains. In fact, the application of PCDEs appeared to be on a continuum from teacher led behaviours in the sampling years towards self initiated PCDEs in the specialisation and investment years. Recognising this, TID models should consider, monitor and develop all the components (e.g. physical, technical, psycho-behavioural) that influence the fulfilment of potential and underpin a performer’s capacity to develop within performance domains. Importantly, this research serves more than academic interest, as findings would sensibly form the basis of TID models as well as broader coaching and development processes.

INFLUENCE OF THE RELATIVE AGE EFFECT ON THE DROPOUT OF A SPORTS ACTIVITY

Delorme, N., Raspaud, M.

University of Grenoble, Grenoble, France

Understanding the determinants of sport dropout is an important issue for the sport federations that want to grow up durably. It is hence fundamental to attract new members while developing the loyalty of current members, notably in youth categories. Loyalty may be developed only after having identified and mastered the factors of dropout.

In sport, cut-off dates are used to put in place different categories of practice according to the players’ age in order to allow a more balanced competition. However, in a system based on the 1st January, a child born in January will have an advantage in physical and cognitive maturity of 11 months compared to a child born in December, though both find themselves in the same age group. Using data from the NHL, Grondin et al. (1984) found a strong over-representation of players born at the beginning of the year and an under-representation of those born at the end. They suggest that this biased distribution is a consequence of the cut-off date in the 1st January which is used to determine the age categories. Indeed, this distribution was explained by a mode of selection preferring an early physical development discriminating against players born late in the competitive year.

Recently, Delorme & Raspaud (in press) reported the existence of a significant relative age effect (RAE) in all youth male and female age categories of French basketball. In addition, they found important differences between the height of the players born early in the competitive year and those born late, the former being taller than the latter. Given that height is the most valued physical attribute in youth categories, players born a long time after the cut-off date may be over-represented among dropout athletes.
The aim of this study was to examine the distribution of the birth dates of the young male (n = 44,498) and female (n = 30,147) French basketball players who dropped out this sport during or at the end of the 2005-2006 season, to examine whether the RAE plays a significant role with regard to this phenomenon. The results showed an under-representation of players born early in competition year and an over-representation of players born late from 9 to 14 years old for males (<0.0001) and from 9 to 17 years old for females (<0.0001). Despite the growing number of articles on this topic, the RAE has not been mentioned in the recent reviews of literature of the psychological and sociological factors influencing the dropout rate of the young sports participants. The results of the present study confirm that this effect should be taken into consideration in studies about sport dropout as a variable that may influence significantly this phenomenon.

4. Physical activity is generally assumed to be beneficial for one’s health. The importance of physical activity in relation to people’s health has resulted in international consensus on guidelines for Healthy Physical Activity. These guidelines contain a minimum quantity and intensity of physical activity. In the Netherlands the Dutch Healthy Physical Activity Guideline (NNGB) is used. The NNGB is based on a minimum of 30 minutes moderate physical activity for five days a week.

5. Earlier research shows that Dutch adult sportsmen are more likely to meet the requirements of the NNGB, than those who do not participate in sports.

6. This research was based however on a simple dichotomy between those who do and those who do not participate in sports. However, the group of sportsmen is not a homogeneous group and is made up of people performing different sports, in different contexts, with differing degrees of participation.

7. In this paper we will therefore further investigate compliance to norms for physical activity within the group of sportsmen.

8. Our analyses, performed on the survey Injuries and Physical Activity in the Netherlands (OBiN- a nationally representative sample of over 5,000 persons), indicate that sportsmen who more frequently take part in sport (at least two times a week) are far more likely to meet the NNGB than the rather large group of sportsmen who participate in sport not more than once a week. The second half of the paper therefore investigates determinants of more frequent sports participation, linking frequent sports participation to organisational setting (club, commercial sports centre, unorganised), main type of sport and motives to take part in sport, as well as standard background variables such as age, gender and levels of education.

9. Our analyses, performed on the survey Injuries and Physical Activity in the Netherlands (OBiN- a nationally representative sample of over 5,000 persons), indicate that sportsmen who more frequently take part in sport (at least two times a week) are far more likely to meet the NNGB than the rather large group of sportsmen who participate in sport not more than once a week.

10. The paper adds to literature on the significance of sports for maintaining healthy lifestyles and to the literature on explaining and understanding sports participation.

THE REGULATION OF THE ECONOMIC STAKE OF FOOTBALL HOOLIGANISM - THE GREEK CASE

Mastrogiannakis, D. University Paris XI, University Lille 2, France

Since the institutionalisation of professional football in Greece in 1979 and the efforts for its modernisation at the end of the 90’s, the championship is mainly characterized by these two phenomena. On the one hand, there is a continuous economic decline of the football clubs; a fact, which is accompanied by the low attendance in the football grounds and on the second, is the permanent manifestation of hooliganism which is something that actually marks this era. Our main assumption, according to Bourdieau’s social theory, suggests that the Greek legislation against football hooliganism constitutes the principle of construction of a specific social field in order to fight against the phenomenon. Having in mind the above mentioned hypothesis, we were brought to identify a hierarchical structured microcosm, between two principal poles: the first one which is the dominating one, is the public pole which consists of the Ministry of Sports and the Ministry of Public Order, and then, the second pole, the dominated, where order the Greek Football Federation, the Professional League and the clubs. Thus, although the fight against hooliganism appears as a ‘game’, which is produced in this social space, it appears as a political one. If this social field is a space of forces and struggles between the actors of the various positions with matter of these stakes, the existence of this one presupposes nevertheless, a collusion of those that are committed there. The aim of this contribution is the presentation of the games between the occupants of the different positions in order to regulate the economic stake, related to the manifestation of the hooliganism.

RISK SPORTS - SOCIAL CONSTRAINTS AND CULTURAL IMPERATIVES

Langseth, T. Sogn and Fjordane University College, Norway

Participation in sport activities involving excitement and risk, such as climbing, surfing, river kayaking, is increasing in the Western world (e.g. Rinehart and Sydnor 2003, Wheaton 2004). In this talk I will identify and discuss two seemingly opposing sociological understandings of the motivations for getting involved in risk sports. Within the compensation model, risk sports are seen as a legitimate way to express affections and desires normally suppressed by societal norms. In this model, voluntary risk taking is seen as a compensation for a highly regulated and constrained modern life. In opposition, the adaptation model sees risk taking as a result of emerging cultural norms that embrace risk. The ethos of risk sports are then seen as concurring with values in present day society. Within the compensation model voluntary risk taking is seen as...
OP-SO01 Sociology 1

a result of a society that is too safe and regulated, whereas the adaptation model sees the same phenomena as resulting from cultural norms that cultivate and worship risk taking.

In the talk I will evaluate the two models’ underlying understanding of society and individual desire development. I will argue that the two models are not necessarily opposites, but that they emphasize different sides of modernity that are simultaneously present. I will use Peter Wagner’s historical sociology (Wagner 1995) to show that modernity simultaneously consists of tendencies of both discipline and liberty. When it comes to understanding actors’ motivation to participate in risk sports, I will scrutinize how the two models understand development of desire. The compensation model understands desire as developing from deeply rooted human needs. The adaptation model on the other hand sees desire as socially constructed. I will use Crossley (2001) to argue that seeing desire as constructed, better explains the rising popularity of risk sports. Nevertheless, many actors find themselves living their daily lives in constraining settings. I will argue that the rising popularity of risk sports to some extent can be explained by the tensions created by a mismatch between desire structures developed from cultural imperatives in late modernity, and the factual constraining settings of every day life.

**WE NEED YOU! - A QUALITATIVE EVALUATION OF PROJECTS FOR INTEGRATION AND PLURALISM WITHIN THE ‘HANDSHAKE’ BETWEEN THE SWEDISH GOVERNEMENT AND SWEDISH CONFEDERATION OF SPORTS**

Lundvall, S.

*GiH, Swedish School of Sport and health Sciences, Sweden*

Between 2004 and 2007, 90 million Euros were given to the Swedish Confederation of Sports (RF) by the Swedish Government in order to stimulate participation in sports for young people. RF gave priority to five areas: open the doors for all, promote girls’ sports, fight against drugs, keep fees down, intensify school cooperation.

Objective

This study is focussing on several years’ projects aiming at integration and pluralism (27 out of 84). The objective has been to i/ describe the project applications through a textual analysis, ii/ explore the fulfilling and challenges of six strategically chosen projects and iii/ to understand the participants experiences of them.

Methods

Six field visits, lasting one day, and semi structured interviews with project leaders, coaches, assisting adults, participants (aged 9-27 yr), parents and school personnel (in total 45) were made. All projects were geographically spread and within multicultural areas in Sweden. As theoretical frame intercultural migration research has been the point of departure for understanding mechanisms behind power distribution, discrimination and exclusion. Ethnicity has been used as an analytical tool on a discursive textual and practical level within the projects.

Results

On a discursive level the majority of the applications illustrated the need of “the others” (participants with immigrant background) in relation to the majority culture represented by clubs and sports associations, describing the lack of meaningful leisure time and physical activities, non-integrated social environments and risk behaviours. Immigrant girls and parents were portrayed as passive, in the need of role models and new norms. Though, 5 out of 27 applications took another ideological stand turning to the need of the sports movement. These projects indicated problems for the sports movement to develop itself and support democratic values without the inclusion of “the others” - claiming for mutual benefits and new methodologies.

The interviews display how new ways of organizing sports became important factors for success. The participants expressed joy of having activities close by their school and living. Girls stressed the importance of getting an arena by their own. In a project for recruiting leaders with immigrant background, problems with discrimination were revealed in terms of earlier and present experiences of discrimination. Parents and assistant adults witnessed never before being approached by the sports community.

Discussion

If the sports movement in Sweden is striving for inclusion and pluralism - steps need to be taken on both a strategically and practical level. People living in multicultural areas are willing to contribute to the process of inclusion and sport participation but on shared premises.

**MANAGING THE PASSION FOR COMPETITION - NIETZSCHE AND THE EUROPEAN SPORT MODEL**

Pires, G., Correia, J., Colaço, C.

*Faculdade de Matricidade Humana - UTL, Portugal*

Introduction

The idea of "agôn" conceptualized as fair and noble competition has a central place in the Friedrich Nietzsche (1884-1900) thinking. Since his first period which occurred under the influence of Wagner and Schopenhauer, marked by texts like "The Birth of Tragedy" (1872), "Homer on Competition" (1872) and "Unlimited Meditations" (1873-1876), Nietzsche, departing from the classics wrote about the nature of human existence, beginning with the struggle for survival, and envisioning the building of success and excellence, which the Greeks named “arête”.

In the present paper we will undertake a close reading of Nietzsche work, exploring the nature of strife, how this strife channels itself into cultural forms, and how these forms according with Nietzsche’s thinking should organize a new paradigm for the “European Sport Model (ESM)".

Methods

In “The Birth of Tragedy” and in “Human, All Too Human” (1878), Nietzsche started the development of a research method which he named “genealogical”, derived from the philological method of research. Its application was done later by means of what the philosopher called “transvaluation of all values in the sense of humankind overcoming”, and conceptualized as an historical process of forming the prevalent moral values represented by the binomial good/evil.

Development

74
The characteristics of the ESM are: (1) corporative, (2) pyramidal, (3) pedagogical, (4) nationalist, (5) standardized, (6) of open competitive leagues, and (7) integrating a vertical structure of social values.

In the "transvaluation of the values" we analysed the present and future meanings of the “ESM” according with the following items: (1) Natural Law; (2); Super-Man; (3) Power Need; (4) Dionysius vs Apollo; (5) Eris; (6) Socrates Demonian; (7) Ostracism Principle; (8) Eternal Return; (9) Good and Evil; (10) State; (11) Democracy; (12) Europe.

The entrance of television in the big sports events, which was really initiated with the Rome Olympic Games (1960), originated the consequent and progressive contamination of sports by the “monies”. So, from the sport point of view the “ESM” is now in a profound identity crisis.

Conclusion

Crossing over the Nietzschean 12 categories with the seven characteristics that determine the ESM we came to the conclusion that the system evolution points hypothetically to a configuration which has the following organizing attributes: (1) under a market economy, (2) network-based, (3) of entertainment industry, (4) "clubist-centered", (5) of variable geometry, and (6) integrating a vertical structure of economic values.

FORMING OF MEDIA IMPERIALISM IN SPORTS AND EFFECT OF COLONIALIZATION ON OLYMPIC WRESTLING

Barna, T.
Semmelweis University Faculty of Physical Education and Sport Sciences (TF), Hungary

Introduction.

Opposing the practice of the previous centuries, the present day financial and political groups of interests reach their aims not by means of military technique, but via media.

The economic, political and cultural capital piled up by the media empires is the result of a kind of modern colonialization. As a consequence of this kind of colonialization, certain nations and social groups lose their previous identity and become defenceless. Sport cannot be an exception from this either, and it is forced to continuously transform/change in favour of increasing Olympic profit. The negative trends having formed during the past decade in the content values of wrestling is continuing.

Methods.

The followings were applied during 1500 bouts (Olympics, World Championships: WCh'85, Atlanta '96, Athen '04, WCh. '05, WCh '07)
Direct recorded information from the minutes of the bouts:
  • number of bouts
  • duration of bouts
  • number of falls
  • number of technical points
  • Indirect observation methods:
    • simple attack
    • complex attack
    • attempted attack and completed attacks are registered on a special survey sheet

Results.

As a result of the changing rules of the past years, wrestlers have minimised their actions initiated from standing, have decreased the number of their complex, but spectacular actions, have set themselves for holds worth one or two points. The number of falls and technical falls decreased to half in the past years, so - although suitable to TV broadcasting - wrestling has gradually lost its spectacle and spirit. The number of technical points for a time unit has not changed, which unambiguously means the devaluation of the contextual value of wrestling, although the length of the bouts shows a tendency to decreased.

Conclusions

Spectacular throws executed from standing should be valued in a way, that it should mean end of the bout. The first action should have a double value and of decisive importance in case of a tie.

OP-TT02 Training and Testing 2

INTER-LUMB COORDINATION PERFORMANCES FOLLOWING A YOUNG BASKETBALL MATCH

Cortis, C., Tessitore, A., Lupo, C., Capranica, L.
University of Molise, Campobasso, Italy

Introduction

Since basketball matches require high-intensity activities (Hoffman et al., 1999; Kalinski et al., 2002), it is possible to hypothesize a decrease in the player’s coordinative performances at the end of the match. Thus, the aim of this study was to verify differences in inter-limb coordination performances following a basketball match in young players.

Methods

Before and after a friendly 4-period basketball match, 10 young players (age: 16±0 years) were administered in-phase (IP) and anti-phase (API) inter-limb coordination (flexions and extensions of hand and foot at 80, 120, and 180 beats/min (bpm) velocities, for 60 s maximum) tests (Capranica, et al., 2004). The intensity of the match was evaluated by means of rates of perceived exertion (RPE) and muscle pain (RMP), and heart rate (HR) expressed as a percentage of HRmax i.e., maximal effort, ME: >95% HRmax; high-intensity, HI: 86-95% HRmax; low-intensity, LI: 76-85% HRmax, active recovery, AR: 65-75% HRmax, passive recovery, PR: <65% HRmax). Differences (p<0.05) were evaluated by means of ANOVA for repeated measures with PLSD post-hoc.
results of endurance athletes’ group showed a clear pattern of occurrence of aerobic-anaerobic transition which is in agreement with practices, experiences of OT, and psychosocial stress. Athletes participated in 7 different sports and 30% competed at national level.

Acknowledgments: Suunto Oy and Myontec Oy for providing technical support.

ANALYSIS OF THE AEROBIC-ANAEROBIC TRANSITION DURING INCREMENTAL TREADMILL RUNNING WITH THE USE OF ELECTROMYOGRAPHY

University of Jyväskylä, Finland

Introduction. A non-linear increase of EMG has been identified as a threshold (EMGT) and its occurrence has been shown to correlate with first (VT1) or second ventilatory (VT2) threshold during cycling [1]. Running presents a biomechanically more complex movement pattern where modest changes in technique can be used to compensate for fatigue [2]. In field conditions during everyday training, novel textile electrodes embedded into clothing [3] could provide a convenient way to determine EMGT. The purpose of this study was to examine use of textile electrodes in detecting aerobic-anaerobic transition during incremental treadmill running.

Methods. 28 males (25±3 yrs, 178±5 cm, 71±8 kg) accomplished VO2max test on a treadmill (3 min ramp model, 1 km/h increments). Subjects were analyzed in two groups: 15 recreationally active (VO2max = 50±7 ml/kg/min) and 12 endurance athletes (VO2max = 64±8 ml/kg/min, 5 endurance runners, 7 orienteerers). EMG using textile electrodes embedded into shorts [3], heart rate (T6, Suunto, Finland), lactate (Lactate Pro) and respiratory gases (Sensor Medics Vmax 229) were assessed. Second ventilatory threshold (VT1), onset of blood lactate accumulation (OBLA) and EMGT using two-segment linear analysis (quadriceps and hamstrings combined) were determined [4, 5 and 1]. Pearson’s correlation coefficients, ANOVA and Bland & Altman procedures were used for statistical analyses.

Results. EMGT of recreationally active subjects did not show a consistent pattern by its timing in relation to VT1 or VT2. However, the EMGT results of endurance athletes’ group showed a clear pattern of occurrence of aerobic-anaerobic transition which is in agreement with VT2 and OBLA methods. There were no significant differences in VO2max at the different thresholds: VT2 occurred at 59.6 ± 5.0 ml/kg/min, OBLA at 62.6 ± 5.0 ml/kg/min and EMGT at 62.6 ± 5.0 ml/kg/min. Correlation coefficient between EMGT and VT2 was 0.77 (P<0.05) and 0.67 (P=0.07) between EMGT and OBLA. The data collection in the athletes group with good quality was 67%. The remaining 33% of data was non-analyzable due to improper size of the shorts where EMG electrodes were embedded [3].

Discussion/Conclusion
Although matches put a heavy load on players, the coordination abilities tend to increase at the end of the match. Actually, a little margin of improvement was expected considering that before the match the players showed high performances when compared to those reported for young sedentary individuals [Capranica et al., 2004]. Therefore, it is possible to speculate that an acute bout of intense exercise exerts beneficial effects on the efficiency of executive and attentive control functions involved in complex motor behaviours.

INCIDENCE OF NON-FUNCTIONAL OVERREACHING IN YOUNG ATHLETES PRACTICING INDIVIDUAL SPORTS

Matos, N., Winsley, R., Williams, C. Children’s Health and Exercise Research Centre, University of Exeter, Exeter, UK

Incidence of non-functional overreaching in young athletes of individual sports

Matos Nuno, Winsley Richard, Williams Craig
Children’s Health and Exercise Research Centre, School of Sport & Health Sciences, University of Exeter, Exeter, UK

Introduction: When the balance between training stress and recovery is disproportionate, an athlete may be at risk of becoming overreached or overtrained. Two studies which investigated the prevalence of overtraining (OT) in young athletes (11-18 years old) reported an incidence of OT of 35% [Raglin et al., 2000] and 37% [Kenia et al., 2001]. However, information concerning the occurrence and nature of OT in younger athletes are still scarce, whilst recording a wider range of symptoms such as upper respiratory tract infections (URTI), apathy, bad mood during times of hard training and not doing enough to meet training goals have been largely ignored. The aim of the study was to assess the incidence of self-reported non-functional overreaching (NFOR) using a more extensive list of associated signs and symptoms in athletic children (Meuuseen et al., 2006).

Methods: Ninety-two athletes (48 girls and 44 boys) with a mean age of 14.7 ± 1.7 y completed a 92-item questionnaire about training practices, experiences of OT, and psychosocial stress. Athletes participated in 7 different sports and 30% competed at national level. Athletes were classified as being NFOR if they reported to ever have experienced daily fatigue and a significant decrement in perform-
ance for long periods of their training. Data were analysed using the Mann-Whitney non-parametric test and statistical significance was set at p < 0.05.

Results: Thirty-four percent of athletes were classified as NFOR. The NFOR athletes reported significantly greater incidence of problems with sleep (p=0.002), URTI (p=0.004), fatigue during periods of hard training (p=0.000), mood fluctuations (p=0.001) and feelings of apathy (p=0.000), and perception of failure to meet self (p=0.001) and coach expectations (p=0.007).

Conclusion: The results have shown that 34% of the athletes have experienced NFOR at least once, and the same signs and symptoms reported in adults are present in children, supporting two other surveys on young athletes (Kenta et al., 2001; Raglin et al., 2000). Over-training seems to be associated with fatigue caused from training and the related psychological and social stressors.

CAN 2000-M ROWING ERGOMETER TIME BE USED AS A VALID PREDICTOR OF 2000-M ON-WATER PERFORMANCE?
A STUDY OF 398 ELITE JUNIOR ROWERS
Mikulic, P., Smoljanović, T., Bojani, I., Hannafin, J., Pedi, I.
Faculty of Kinesiology, University of Zagreb, Zagreb, Croatia

Introduction
Rowing ergometers are designed to simulate movements performed during on-water rowing and are widely considered to be valuable tools for rowing training, the evaluation of rowers’ sport-specific performance, and the detection of any changes in performance capacity. The aim of this study was to predict on-water rowing performance, as measured by final rankings at the most important competition for junior rowers the FISA World Rowing Junior Championship (WRJC), based on the 2000-m ergometer times in a sample of 398 male and female junior rowers competing in all 13 events of the 2007 WRJC.

Method
At the FISA WRJC (Beijing, People’s Republic of China, 8-11 August 2007), a total of 398 junior rowers from 45 countries were interviewed using a questionnaire. The sample included competitors participating in 13 events held during the Championship, as well as the reserves (1.3% of the sample). Coxswains were not included. The sample represented 65.9% of all competitors, including 52.5% of the A finalists as well as 39.9% of the medallists. Following the exclusion of invalid data, the sample eventually comprised 382 junior rowers (222 males and 160 females) who entered statistical analyses. Out of 382 rowers, 360 (94.2%) used a stationary Concept II rowing ergometer for testing purposes, 15 (3.9%) used a Concept II rowing ergometer on slides, and 7 (1.8%) used a RowPerfect rowing ergometer.

Results
In all 13 events the competitors’ 2000-m ergometer times were significantly (P<0.05-0.001) correlated with their final WRJC rankings. The highest correlations were obtained for the rowers’ ergometer times in women’s single sculls (r=0.922) followed by men’s single sculls (r=0.804) and women’s double sculls (r=0.793). The obtained correlations are generally higher for smaller boats i.e. singles, doubles and pairs (r=0.638-0.922) than for larger boats i.e. quads, fours and eights (r=0.308-0.699). Simple regression analyses were used in order to define the prediction models, and the highest predictive power (R²=0.850, SEE=1.96) was obtained for women’s single sculls.

Discussion and conclusions
The main findings of the present study are that the 2000-m rowing ergometer times of competitors participating in all 13 events of the 2007 WRJC are significantly (P<0.05-0.001) correlated with their final championship rankings and that improvements in their final rankings correspond to improvements in rowing ergometer times. Although the majority of obtained correlation coefficients range from medium to very high, the use of ergometer times for predictions of on-water performance is limited by the fact that on-water rowing requires specific techniques compared to rowing on an ergometer e.g. manipulation of the oar handle, the synchronization of individual motor performances in team boats, and is performed under various environmental conditions, all of which cannot be measured on an ergometer.

EFFECTS OF IN- AND EXPIRATORY MUSCLE TRAINING ON RUNNING PERFORMANCE
Sperlich, B., Fricke, H., de Maréès, M., Mester, J.
German Sport University Cologne, Germany

Introduction: The fatigue of respiratory muscles (RM) during exercise is being debated to have a limiting effect on physical performance. During rest 2-4% of the entire oxygen consumed (VO2) is used for metabolism in RM. During heavy exercise this amount increases to 10-16% of maximal VO2 (KROIDL et al. 2007, SCHARDT 2005). In this case oxygen consumed by RM may compete against peripheral consumption.

During rest 2-4 % of the entire oxygen consumed (VO2) is used for metabolism in RM. During heavy exercise this amount increases to 10-16% of maximal VO2 (KROIDL et al. 2007, SCHARDT 2005). In this case oxygen consumed by RM may compete against peripheral consumption.

In conclusion with findings of MCCONNELL/SHARPE (2005), WILLIAMS et al. (2002) & HART et al. (2001). The RMT performed in this study corresponds to improvements in rowing ergometer times. Although the majority of obtained correlation coefficients range from medium to very high, the use of ergometer times for predictions of on-water performance is limited by the fact that on-water rowing requires specific techniques compared to rowing on an ergometer e.g. manipulation of the oar handle, the synchronization of individual motor performances in team boats, and is performed under various environmental conditions, all of which cannot be measured on an ergometer.

COMPARISON OF THREE DIFFERENT TEST PROTOCOLS IN SWIMMING

Zinner, C., Krueger, M., Sperlich, B., Mester, J.

1 Institute of Training Science and Sport Informatics, 2 German Research Center of Elite Sport, Germany

Introduction
Many different step test protocols exist for defining training workload in competitive swimming. When performing step tests in swimming without flume the distance of each step remains the same while the time per step decreases. Step distance of 200m or shorter will lead to an exercise time shorter than 2 seconds. A step shorter than 2 minutes is too short to achieve steady state in lactate concentration during incremental testing. Many coaches, even those working with elite athletes, use the results of these tests to control their training. Very often the workloads for the lower training paces given by these tests are much too low for the swimmers. The aim of this study was to compare two common test designs with a test protocol with constant time length for every step, common to the test designs on a treadmil.

Methods
20 male swimmers participated in the study (17.8±3.7 years, 184±7.6 cm, 77.1±8.4 kg). The first protocol was a set of 7x200m, start every 5 min. The pace for the 1st 200m was personal best+35 sec. Following 200m time should decrease by 5 sec.

The second step test protocol consisted of 5 steps. It was a set of 8x200m with varying rest periods. The velocity of the first step should be 70-85% of personal best. The last swim was supposed to be personal best. After each swim blood samples were taken for lactate measurement, and heart rate was measured immediately. After the last swim lactate was continuously measured until the 10th minute.

Results
The mean velocity at 2mmol/l lactate in the 7x200m protocol was 1.25±0.06 m/s, in the second protocol 1.24±0.07 m/s and in the third protocol was 1.25±0.06 m/s.
At 3mmol/l lactate the velocities were 1.30±0.06 m/s in the 7x200m, 1.28±0.07 m/s in the second test and 1.29±0.07 m/s in the third protocol.

The mean velocities for fixed 4mol/l lactate threshold were: 7x200m 1.31±0.07 m/s, second test 1.31±0.07 m/s, third protocol 1.32±0.07 m/s. At lactate values of 2, 3 and 4mol/l, there are no significant differences in velocity between the three protocols.
In the fastest mean velocity in the final step was achieved in the second test protocol (1.46±0.08 m/s). The final velocity in the 7x200m test was 1.43±0.09 m/s and 1.39±0.06 m/s in the 3min-step-protocol.

Discussion
All three test designs showed no significant differences in the velocities at 2mmol/l, 3mmol/l and 4mmol/l lactate between the different protocols. The decreasing time of the steps during swimming tests is no criterion which leads to results, which can't be compared with the results of tests with constant steps. Nevertheless the velocities given by these tests for aerobic training workouts are too high. The athletes won't stay in aerobic metabolism after a short time of training.

PS-2 Metabolic syndrome - Obesity & Diabesity

THE HARD EVIDENCE THAT AN ACTIVE LIFESTYLE PREVENTS METABOLIC SYNDROME

Wagenmakers, A.

University of Birmingham, United Kingdom

The World Health Organisation predicts that in 2020 sixty-70% of all chronic diseases leading to death will be lifestyle related. The combination of physical inactivity and an imbalanced nutrition containing too many calories and fat will lead to further epidemic increases in obesity, metabolic syndrome, type 2 diabetes and cardiovascular disease and become the biggest premature killer. In order to make individuals and populations change lifestyle it is important to understand the physiological and biochemical mechanisms by which an unhealthy lifestyle leads to the metabolic syndrome and related pathologies and the health benefits of regular exercise. This lecture will first describe the metabolic impairments that result from the combination of too little exercise and too many calories. Uncomplicated gains in body weight will soon be followed by obesity and via mechanisms that among others involve a plasma fatty acid/lipid overload and inflammation lead to functional impairments of the (micro)vascular endothelium, insulin resistance, type 2 diabetes and cardiovascular disease. A high frequency of these previously named age-related chronic diseases is now observed in children and adolescents in most countries worldwide. Single bouts of exercise have many biological benefits not only in healthy lean, but also in obese individuals and patients. Selected examples will be given of the metabolic effects of individual bouts of exercise on insulin sensitivity of skeletal muscle and function improvements of the vasculature. Large accumulative effects are observed in individuals training 3-4 times a week for several months up to more than 1 year. The adaptability of the muscle is remarkable both in terms of its ability to oxidize fat, but also in its ability to regain sensitivity to insulin. Changes in the vascular wall are reversible as well and the current literature seems to suggest that these changes may be even faster and achievable at lower training loads. Even severe cardiovascular pathology is reversible when the exercise program is intense enough and supervised by professional trainers. The success of voluntary lifestyle intervention programs, involving both exercise and diet, either undertaken individually or in groups in achieving measurable biological effects is rather minimal though and this is among others related to the strong intrinsic motivation that is needed to perform intense exercise training and reduce food intake for prolonged periods of time (covered by Joan Duda). Very important also are the exercise infrastructure limitations in a highly populated world with a high traffic density. Modification of inner city infrastructures with traffic free walking and cycling lanes should have the highest possible priority of governments and public health authorities.

NEW APPROACHES TO PROMOTING AN ACTIVE LIFESTYLE
Duda, J.
University of Birmingham, United Kingdom

There is currently a considerable amount of evidence regarding the impact of regular engagement in physical activity (PA) on physical and mental health. We also now know more about the physiological and biochemical mechanisms by which exercise contributes to health as well as the means by which inactivity can lead to metabolic disorders and disease states. However, despite these marked advances in our knowledge base, there is a large and increasing percentage of the population who do not participate in PA at the intensity and frequency necessary to accrue the health benefits associated with regular exercise. Interventions to promote PA levels have involved informational campaigns and modifications of the physical environment so that it is more conducive to an active lifestyle. Community-based PA promotion programmes have also been done. This presentation centres on individual-based intervention strategies and, in particular, speaks to the importance of personal autonomy regarding successful behavioural change. Pulling from Self-Determination Theory (SDT; Deci & Ryan, 2000), people are autonomously motivated when they engage in an activity or cease an activity for reasons that come from within the self and are freely chosen. Research grounded in SDT has associated autonomous motivation with improved attendance and greater reductions in body mass indices within weight reduction programmes, long-term medication adherence, improved glycemic control and dietary self-care in diabetes patients, reductions in intensity and frequency of smoking in adolescents, and maintained smoking cessation in adults. Recent research findings will be presented (e.g., Edmunds, Ntoumanis, & Duda, 2007a,b) regarding the role of self determination, and its social environmental determinants, to PA engagement.

treadmill exercise (60 min, 28 m/min, 0% grade) program on plasma, liver and skeletal muscle ATP contents in wild type male rats. Methods: forty male Wistar rats (age 17 weeks, 218 +/- 1.6 g) used for this study and divided into four; fed-control, fed-exercise, fast-control, and fast-exercise. Animals were sacrificed 24 hours after the last session of exercise, the blood and tissue samples were collected. ATP was measured by using an enzymatic (luciferine-luciferase) method. Normal distribution of dependent variables was documented by Kolomogorov-Smirnoff test. The data were analyzed by ANOVA univariate and one way ANOVA. The level of statistical significance was set at P<0.05. Results: the data indicate that the level of liver ATP was significantly higher (P<0.028) in trained group when compared with control group. A higher but non-significant plasma and muscle ATP concentrations were observed in trained rats. However, fasting lowered liver, plasma, and muscle ATP contents only in control not trained-fasted rat. Discussion: the main finding of this study was a higher levels of liver ATP in trained rats following the treadmill training. Data also shows training attenuated a fasting-induced reduction of ATP in the liver, plasma, and muscle. A non-significant increase in plasma ATP levels might be related to the release of ATP from blood cells (erythrocyte and leukocytes) and a non-significant increase of muscle ATP content following treadmill exercise due to incomplete recovery of muscle glycogen content which acts as a source of ATP synthesis. This the first study which investigate the effects of 10 weeks of treadmill exercise training on plasma, liver and muscle ATP contents at rest. Conclusion: a higher resting liver ATP might be due to an exercise-induced increase in liver glycogen content and ATP uptake from plasma.

### A SINGLE CIRCUIT-RESISTANCE EXERCISE HAS NO EFFECT ON PLASMA OBESTATIN LEVELS IN FEMALE COLLEGE STUDENTS

Saghebipo, M., Ghanbari-Niaaki, A., Maraki, H., Rajabi, H., Hedayati, M.

Birjand University, Tarbiat Modares University (TML), Birjand University, Tarbiat Moallem University, Shaheed Beheshti University of Medical Sciences, Iran

Obestatin is a 23 amino acid peptide recently isolated from rat stomach that is encoded by the same gene as ghrelin[1,2]. Although ghrelin and obestatin originate from the same precursor prepropeptide, Most reports suggest that obestatin has opposite action to ghrelin on food intake and energy balance[1,4]. Until now, obestatin’s biological effects have been tested only in mice and rats[2,3]. The specific aim of the present study was to investigate the effect of a single session circuit resistance exercise (CRE) on plasma obestatin and growth hormone (GH). Twenty volunteer young female lage 22.84 ± 0.57 year, height 162.37 ± 1.2 cm, body weight 54.02 ± 1.7, and body mass index (BMI) 20.40 ± 0.415 kg/m²) were randomly divided into four: 40, 60, 80% one-repetition maximum (1RM) and combined (40+60+80%) load groups (COL). Subjects performed a single session of CRE, consisting of 3 sets of 9 exercises (25 seconds per each exercise with 1 minute interval between each set). Blood samples were collected before and immediately following the exercise protocol. Changes in plasma obestatin levels were not significant within and between groups. Plasma GH concentrations were significantly higher (P<0.001). Results of this protocol of sprint exercise training are consistent with previous work that demonstrates an increase in lipid peroxidation in response to high intensity exercise [3, 4]. Indeed, the present study indicates that long-term, high intensity training can effectively reduce the role of oxidative stress by cause adaptation in antioxidant systems that confirm prior studies. However, detraining reversed improvement.
Obestatin is a 23 amino acid peptide recently isolated from rat stomach mucosa. It is encoded by the same gene that encodes ghrelin; however, obestatin has an opposite effect on food intake and plays a role in energy balance. The purpose of the present investigation was to determine the effect of various periods of endurance and sprint training on lipoperoxidation (MDA) and antioxidant defence system including Ferric Reducing Ability of Plasma (FRAP), bilirubin, uric acid and total protein. Methodology. A total of 54 three month old rats were selected for this purpose and they were randomly assigned to three groups of endurance training (n=18), sprint training (n=18), and control group (n=18). The rats in the experimental conditions performed an either an endurance or sprint training program for 12 weeks, three time a week. The training protocols were designed based on oxygen cost (intensity of the endurance training was set at 1%70-80, while for the sprint training group was set to 1%100 v02max). The variables of interest were measured at three intervals using kit (bilirubin, UA and TPI, TPTZ reagent (MDA) and Thiobarbituric acid marker (FRAP)).

Results and conclusion. The results of analysis by using of Two way repeated ANOVA showed that no significant changes occurred within the control condition, where as, considering MDA, bilirubin and uric acid in endurance training group and based on MDA, FRAP, bilirubin and uric acid within the sprint training group significantly changed. Also, the type of training (sprint vs. endurance) had a significant effect on FRAP (p=0.001) and bilirubin (p=0.008), while no significant changes was found for MDA, uric acid or total protein. In summary, the findings of this research indicated that participation in regular endurance or sprint training program leads to the improvement in oxygen cost and immune cell number. Fifteen healthy and trained men were randomly assigned to one of two groups: control or N-acetylcysteine (NAC, 1200 mg ·d·1 for 8 days prior to and 600 mg on the day of exercise trial). To measure the ergogenic effectiveness of NAC, athletes performed incremental cycle exercise until exhaustion.

NAC administration elevated the resting and post-exercise total antioxidant status (TAS) by 33–57% and reduced level of oxidative stress markers i.e. protein carbonylation (PC) and lipid peroxidation (TBARS) by more than 30%. The plasma PC and TBARS did not correlate with muscle damage markers and immune cell numbers. NAC significantly influenced on number of pathological cells at post-exercise i.e. neutrophils and monocytes increased by 30–64% whereas lymphocytes decreased by 40% compared with control group. The activities of creatine kinase (CK) and lactate dehydrogenase (LDH) were reduced by NAC by more than 30% at post-exercise period. NAC did not cause any changes in myoglobin (Mb) and interleukine-6 (IL-6) levels. All tested markers of muscle damage directly correlated with number of lymphocytes and monocytes. NAC treatment, in the contrary to expectations, did not significantly affect exercise performance.

ASSOCIATION BETWEEN 5-HT1B RECEPTOR GENE (HTR1B) G861C POLYMORPHISM AND THE LEVEL OF PHYSICAL ACTIVITY

Slowinska-Lisowska, M., Haber, E., Jozkow, P., Laczmanski, L., Medras, M.
University School of Physical Education, Poland

Relationship between genetic factors and physical fitness is evident, but the actual role of genes for adherence to physically active lifestyle has not been fully elucidated. The 5-HT1B receptor has been implicated in several psycho-pathologies including pathological aggression, [Saudou et al. 1994], suicide [Youg-yu et al. 2003] and attention deficit hyperactivity disorder [Smoller, 2006]. Animal studies confirmed that stimulation of 5-HT1b receptor increases locomotor activity [Tatarczynska E et al. 2005].

The aim of our work was to search for relationships between 5-HT1B Receptor Gene (HTR1B) G861C polymorphism and level of physical activity in men living in Lower Silesia (Poland).

The study was carried out on 387 men aged 24-72 (mean 47±12). Their mean weight, height and BMI were respectively 85±13 kg, 176±6 cm and 27±4. The most frequently reported diseases were: arterial hypertension (21% of subjects), chronic low back pain (19%), benign prostatic hyperplasia (5%) and diabetes (4%).

Level of physical activity in studied subjects was determined with use of International Physical Activity Questionnaire (last 7-day recall) [http://www.ipaq.ki.se/]. Subgroups presenting high, moderate and low level of physical activity were distinguished.

Genomic DNA was isolated from EDTA anticoagulated whole blood by using standard methods. The polymorphism estimation of the HTR1b (G866C) gene was made by polymerase chain reaction (PCR) and minisequentioning (SNAP-shot kit, Applied Biosystems) in ABI 310 sequenator (Applied Biosystems).

Relationship between physical activity level and the polymorphism of the serotonin receptor gene were evaluated by non-parametric test ch2. The trust level p>0.05 was defined as statistically significant.

The statistical discordance was confirmed in the particular genotypes frequency distribution in persons declaring low physical activity and the according Hardy-Weinberg principle.

In persons declared their moderate and high physical activity the genotypic distribution of the polymorphism G861C Serotonin Receptor 1B Gene (HTR1B) was compatible (P>0.05) to this expected under Hardy-Weinberg equilibrium. We conclude that there is an association between 5-HT1B serotonin receptor gene (HTR1B) G861C polymorphism and the level of physical activity in men.

CAG REPEAT POLYMORPHISM IN THE ANDROGEN RECEPTOR GENE AND THE LEVEL OF PHYSICAL ACTIVITY

Slowinska-Lisowska, M., Jozkow, P., Laczmanski, L., Medras, M.
University School of Physical Education, Poland

Though an association between genetic factors and physical fitness is evident the actual role of genes for adherence to physically active lifestyle has not been fully elucidated.

Androgens are thought to influence sport performance, increase activity and aggressiveness. Differences in the length of the CAG repeat may not only affect function of multiple body organs [Langdahl 2003], but mental status and mood as well [Harkonen 2003].

Our aim was to search for associations between CAG repeat polymorphism in the androgen receptor gene and the level of physical activity in men living in Lower Silesia (Poland).

The study was carried out on 387 men aged from 24 to 72 (mean 47±12). Their mean weight, height and BMI were respectively 85±13 kg, 176±6 cm and 27±4. The most frequently reported diseases were: arterial hypertension (21% of subjects), chronic low back pain (19%), benign prostatic hyperplasia (5%) and diabetes (4%).

Level of physical activity in studied subjects was determined with use of International Physical Activity Questionnaire (last 7-day recall) [http://www.ipaq.ki.se/]. Subgroups presenting high, moderate and low level of physical activity were distinguished.

Genomic DNA was isolated from EDTA anticoagulated whole blood by using standard methods. Number of the GAC repeats of the androgenic receptor gene was performed by polymerase chain reaction (PCR). The amplifiacation product was analysed using capillary electrophoresis (ABI PRISM 310).

The investigated group was divided into subgroups of different activity level: high, moderate and low.

Comparison of CAG repeat polymorphism in distinguished subgroups was performed by one-way ANOVA. The level of statistical significance was defined at p<0.05.

We did not find any statistically significant differences of AR length and CAG repeat polymorphism in subjects presenting different levels of physical activity.

Furthermore we did not find any association between AR CAG repeat polymorphism and the level of physical activity in healthy men. This work is supported by the Ministry of Science and Higher Education of Poland (grant code:2PO5D 0730).

Introduction

Satellite cells are the stem cells of skeletal muscle cells and play an important role in the development and regeneration process. They are located between the sarcolemma and the basal lamina of the muscle fiber. The cytoplasm of the satellite cells contains myonuclei and myofibrils. The function of the satellite cells is regulated in relation to the insulin. Larger concentration of lipolysis during effort also influences reduction of excess fatty tissue increasing quality of life and the energetic profile.

Results

Three-week-old and 12-week-old female ICR mice were used. Five animals from each age group were used in this experiment. Randomly 300 nuclei surrounded by the basal lamina of the soleus muscle fiber were observed in each animal. All of the nuclei were divided into satellite cell nuclei or myonuclei from the SEM images. The percentage of satellite cells nuclei (satellite cells/ myonuclei) was calculated in each animal.

Discussion

In the present study, satellite cells were detected by SEM and the fluorescent antibody method. The percentage of satellite cell nuclei was higher in young animals. This was in agreement with the previous study [2]. It seems that the percentage of satellite cells declines with age. The fluorescent antibody method allowed detection of satellite cells and myonuclei. However, for more accurate detection, examination using several antibodies for satellite cells is necessary. Based on these results, it is suggested that SEM is an accurate and convenient method for detecting satellite cells.

HORMONAL AND METABOLIC RESPONSE IN MIDDLE-AGED WOMEN TO MODERATE PHYSICAL EFFORT DURING AEROBIC TRAINING

Charmas, M., Opaszowski, B., Charmas, R., Róaska, D., Jówko, E., Sadowski, J.

Faculty of Physical Education in Biola Podlaska, Josef Pilsudski University of Physical Education in Warsaw, Poland

Due to the metabolic changes, the physical effort of the weak factor stimulating the secretion of hormones, and the intensity of the hormonal response depends on e.g. the intensity and duration of the effort. Beside the 24-hour rhythm, also the systematic physical training modulates the intensity of the hormonal reaction. Especially, the aerobic training is illustrated in hormonal adaptation to the effort, through modification of the metabolic profile. In particular, this refers to relations between improvement of respiratory efficiency and better use of fatty compounds and preservation of the carbohydrate reserves of the organism by activation of those hormones that are counter-regulative in relation to the insulin. Larger concentration of lipolysis during effort also influences reduction of excess fatty tissue increasing our BMI. Popular "aerobics" activities are aimed e.g. at regulation of the body weight, accompanied by appropriate diet, and improvement of the physical efficiency factors. It is in particular important in case of middle-aged women, where lack of physical activities may cause increased obesity. Therefore, our research is aimed at observation of the selected metabolic and hormonal factors in women subjected to systematic aerobics training. Group (n=13) of women aged on average 37.4 years exercised with music (aerobics) for a period of 12 weeks, 3 times a week for 60 minutes. Prior to the training (I series), after 6 weeks (II series), and at the end of the period (III series) one standard aerobics session was monitored. The blood samples were taken before and after the session, to mark the concentration of lactic acid, glucose, free fatty acids, insulin, growth hormone, testosterone and cortisol. The heart rate was registered (HR). In each series of tests, forced dehydration caused significant (P<0.05) reduction in the body weight, increased concentration of LA, reduction in glucose and increased free fatty acids. Similarly, the significant (P<0.05) forced increase in GH and reduced insulin concentration was noticed. In case of cortisol, the changes were irrelevant. Similarly in case of insulin, the declining tendency was seen statistically irrelevant. Several weeks of training caused the tendency to reduce the biological cost of 60 minutes of effort in the women tested. It was found that the post-effort concentration of LA in the III series was smaller than that of the II series of tests. Similarly as in case of free fatty acids, glucose, and GH concentration. It was accompanied by smaller average increase of HR. This may emphasize the smaller energy cost of the exercises practiced with simultaneous increase of physical efficiency (technique of activity) of the women subjected to training. At the same time there were no adverse hormonal responses, the energetic profile was stable, the body weight was maintained, which means that the results of the training were beneficial.

SALIVA SECRETORY IMMUNOGLOBULIN A RESPONSE TO ACUTE MODERATE EXERCISE IN OLDER RATS

Tsukuba University, Japan

Background: Secretory immunoglobulin A (SgA) plays the major role in effective specific immunity and provides protection of mucosal surfaces via several mechanisms. Polymeric immunoglobulin receptor (pIGR) on the surface of the epithelial cells combines with immu-
noglobulin A to form SIgA. Ageing is associated with a functional decline in several components of the immune system. Moderate exercise training may attenuate the impact of ageing on the immune system, such as SIgA. However, it is uncertain how moderate exercise affects the process of SIgA secretion in older individuals.

Objective: The intent of this study was to describe the impact of acute moderate exercise on SIgA concentration in saliva and pIgR mRNA expression in salivary gland of older rats.

Methods: Male Wistar rats were assigned to treadmill running exercise (Ex group: N = 6) or remained sedentary (Con group: N = 6). In the Ex group, rats ran for 30 min at 15 m/min-1, and their saliva was collected before and after exercise, the salivary glands were removed after exercise. In the Con group, saliva collection and gland removal were also performed, but the rats did not exercise. SIgA concentration in saliva was measured by ELISA, and pIgR mRNA expression in the glands was analyzed by the 7500 Fast Real Time PCR System.

Results: The mean SIgA concentration in the Ex group was 11.12 ± 5.20 µg/mL before exercise and 11.15 ± 5.62 µg/mL after exercise. On the other hand, the SIgA concentration in the Con group was 6.45 ± 2.82 µg/mL before the Ex group began its exercise session and 6.08 ± 3.21 µg/mL after the exercise. There was no significant change in SIgA concentration in both groups. Expression of pIgR mRNA was 0.71 ± 0.64 Ex and 0.97 ± 0.23 Con, respectively. There was also no significant effect of acute moderate exercise on pIgR mRNA expressions in salivary gland.

Conclusion: The findings of this study was that acute moderate exercise have neither affect on SIgA in saliva nor pIgR expression in salivary gland of older rats.

EFFECT OF EXHAUSTIVE EXERCISE AND LONG-TERM MODERATE EXERCISE TRAINING ON MACROPHAGE IMMUNORESPONSE IN MICE

Chungnam National University, Korea, South

Objective. The present research was to investigate the effect of Exhaustive exercise and long-term moderate exercise training on macrophage immunoresponses in mice.

Methods. Male Balb/c mice (4 weeks, n = 30) were used and randomly divided into 3 groups; Control group (CON, n=10), Exhaustive exercise group (EXH, n=10, 14-28 m/min, 5%, 90 min at 16 weeks) or Moderate exercise group (TRA, n=10, 10-14 m/min, 5%, 30-50 min/day, 5 day/week for 16 weeks). 4% Thioylate (1/2 ml) was used to collect peritoneal M. To identify M cells, CD11b was incubated with the cells for 30 mins. Then, Phagocytosis, CD 86, NKC II, LPS or IFN induced Nitric Oxide (NO) production, proliferation and Cytoxines (IL-1, IL-12, TNF-α) were measured. To measure phagocytosis, M cells (1 X 106cells/150ul) were treated with Dextran MW 70,000 at 37°C with 5% CO2 in humidified air for 2 hours, compared to control at 4°C. To measure NO, M cells (2 X 105cells/well) were cultured at 37°C with 5% CO2 in humidified air for 24 hours with LPS (1ug/ml) or LPS (0.5ug/ml)/IFN (100U). Then, Sulfanilamide, NED Griess Reagent and nitrile standard were used. To measure cytokines, commercial ELISA kits were used. Repeated measures ANOVA and One-way ANOVA were used and p value under 0.05 was considered as statistical significance.

Results. Weight of training group was significantly lower than that in both CON and EXH groups at 2, 10, 15 and 16 weeks. Both exhaustive exercise and long-term moderate exercise training enhanced M phagocytosis as compared to CON group. NO, CD86 and MHC were not significantly changed by both exhaustive exercise and long-term moderate exercise training. M presenting IL-12 in training group was higher than that in both CON and EXH. M proliferation was not affected by both exhaustive exercise and long-term moderate exercise training. IL-15 and IFN were slightly but not significantly changed by both exhaustive exercise and long-term moderate exercise training. Conclusion. It seemed that both exhaustive exercise and long-term moderate exercise training can enhance M phagocytosis. We did not find any significant evidence that exhaustive exercise suppressed M immunorespense. However, it is clear that long-term moderate exercise training could positive effect on M immunorespense by improving phagocytosis and presenting IL-12 which helps Th1 cells.

THE EFFECTS OF A 30 HOUR PERIOD OF SLEEP DEPRIVATION ON SELECTED IMMUNE RESPONSES TO EXERCISE

Costa, R., Cartner, L., Oliver, S., Laing, S., Bilzon, J., Walsh, N.

Bangor University, United Kingdom

Objective. To determine the effects of a 30 h period of sleep deprivation on selected immune responses to intense exercise.

Methods. Using a repeated measures cross-over design, eleven healthy males completed two trials separated by seven days. On one occasion participants slept normally (8 h) and on another occasion they were deprived of sleep for 30 h. Nutrient and fluid intake was prescribed and controlled to meet daily requirements on the day prior and during both trials. After 30 h participants performed 30 min exercise. On one occasion participants slept normally (8 h) and on another occasion they were deprived of sleep for 30 h. Nutrient and fluid intake was prescribed and controlled to meet daily requirements on the day prior and during both trials. After 30 h participants performed 30 min exercise. On one occasion participants slept normally (8 h) and on another occasion they were deprived of sleep for 30 h. Nutrient and fluid intake was prescribed and controlled to meet daily requirements on the day prior and during both trials. After 30 h participants performed 30 min exercise.

Results: No significant trial x time interaction was observed for circulating leukocyte, neutrophil, lymphocyte, T-lymphocyte subset (CD3+, CD4+, CD8+) counts, bacterial-stimulated neutrophil degranulation, S-IgA concentration and secretion rate. However, a main effect of time (P< 0.01) was observed for the leukocytosis (9.7 ± 1.1 X10^9/L), neutrophilia (6.6 ± 1.0 X10^9/L), and lymphocytosis (1.2 ± 0.3 X10^9/L) post TT. Significant increases in circulating CD3+ and CD8+ subsets (P< 0.05) and decreases in bacterial-stimulated neutrophil degranulation per neutrophil were observed post TT (24% post TT and 23% 2 h post vs. 30 h, P<0.01). The TT also increased S-IgA concentration (61% vs. 30 h, P< 0.05) but did not alter S-IgA secretion rate. The observed changes were mainly attributed to circadian variation and exercise-induced immune alterations.

Conclusion. A 30 h period of sleep deprivation does not alter resting immune response or the immune response to intensive exercise.
EMG REACTION TIME AND MUSCLE ACTIVITY PATTERNS IN THE UPPER LIMBS FOR KENDO STRIKES

Yotani, K., Tamaki, H., Ogita, F., Takekura, H., Kirimoto, H., Kitada, K., Yuki, A.
National Institute of Fitness and Sports in KANoya, Japan

PURPOSE
Visual stimulation-reaction time and muscle activity patterns in the upper limbs during kendo strikes were assessed using an electromyo-
graphic [EMG] reaction time.

METHODS
Twenty-one males (kendo athletes: KA [n=7], non-kendo athletes: non-KA [n=7], non-athletes: sedentary [n=7]) were asked to per-
form kendo strikes in response to visual stimulation from a flashing light signal. The strikes, Hiki-Men (HM) to the frontal region of the head and
Hiki-Kote (HK) to the right wrist, were performed as quickly as possible with a bamboo sword (shinai) using the upper limbs. EMG signals
from bilateral biceps brachii, bilateral triceps brachii and the right flexor carpi ulnaris muscles were recorded together with elbow joint
angle and hitting shock. Muscle activity patterns, total task time (TTT), pre-motor time (PMT), motor time (MT), and action time (AT) were
measured for the HM and HK tasks. Photo-stimulation body reaction time (BRT) was also measured.

RESULTS
BRT in both athlete groups (KA and non-KA) was significantly shorter than that in the sedentary group (P<0.05). No significant differ-
ences were seen between KA and non-KA. TTT and AT in HM and HK tasks were also significantly shorter in athlete groups than in the
sedentary group (P<0.05). However, no significant differences were observed between KA and non-KA for TTT, PMT, MT or AT in HM and
HK tasks. In muscle activity patterns at HM and HK tasks, the timing of muscle recruitment in accordance with different striking tasks was
altered by KA, but not by non-KA or sedentary. Significant strong positive correlation were observed between PMT and TTT for both HM
and HK tasks in athletes (P<0.01, r=0.88-0.93) and sedentary subjects (P<0.01, r=0.97-0.98). Furthermore, significant strong positive
correlations were observed between MT and TTT for HM (P<0.05, r=0.76), AT and TTT for HK (P<0.05, r=0.76) in the sedentary group. Z-
test showed that the coefficient of correlation [r] between TTT and PMT was highest in the athlete groups.

DISCUSSION/CONCLUSION
These results suggest that no differences exist in time factor on neuromuscular function for HM and HK tasks between KA and non-KA.

PREVENTION OF ACUTE AND CHRONIC OVERUSE INJURIES OF THE LOWER LIMBS IN SPORTS

Reule, C., Alt, W.
University of Stuttgart, Germany

Introduction: The prevention of acute and chronic overuse injuries is of major importance to athletes, especially high performance ath-
estics. High risk sports are already identified. However, little is known of the diagnostics of individual and specific risk factors. Therefore,
the aim of this study is to identify the relationship between individual anatomical factors of foot and ankle and acute and chronic overuse
injuries by means of a new diagnostic measurement system and a treadmill-analysis.

METHODS: A ultrasonic pulse-echo based measurement system (modified Zebris technology®) (HOCHWALD 2004) determines the axis of
the talocrural and talocalcaneal joint in vivo and in real time. This method is based on a movement analysis of the foot and tibia. Arch
index, the angle of gait, and the center of pressure will also be determined by a treadmill that enables plantar pressure measurement.
Video-analysis will allow for analysis of the rolling motion of the foot while walking. Anamnesis data are collected with a questionnaire.
Participants: 293 subjects mainly including long distance runners with a running performance of at least 25 km per week and a running
history of 3 years were measured so far.

Findings: Until now 586 talocrural and talocalcaneal axis were determined. 444 of these were included. The average of the inclination
angle of the talocalcaneal axis was 40° and the deviation angle 13°. 218 out of 293 tested subjects (74%) have been injured before. We
counted a total of 682 injuries. 23% of these injuries were located at the ankle, 20% at the knee and 14% at the achilles tendon. Discussion:
The work is still in progress. Until now the average of inclination angle (40°) approximates the conclusions of ISMAN (1969)
(41°). In contrast to this the average of deviation angle is lying between the conclusions of ALT (2001) and ISMAN (1969). Maybe the differ-
ence between the results is based on the difference of used methods. A direct comparison between both methods seems to be needful.
Next step is to determine the relationship between the collected anatomical individual factors and the overuse injuries by means of
statistical-analysis. This will be continued till June 2008.

COMBINED EFFECTS OF STRETCHING AND RESISTANCE TRAINING ON THE ANKLE JOINT RANGE OF MOTION

Kato, E., Mitsukawa, N., Miyamoto, N., Iwai, T., Fukunaga, T., Kawakami, Y.
Waseda University, Japan

Introduction
The use of stretching to improve flexibility is a widespread practice among athletes and normal individuals. As a measurement of flexibil-
ity, active and passive joint range of motion (ROM) is often used (Gehlsen and Whaley, 1990). The former is especially important in physi-
cal activities, and can be influenced by the extensibility of muscle and tendon and muscle strength of the agonists (Altet 1996). The pur-
pose of this study was to examine the effect of a 6-week program of combination of static stretching of plantar flexors and resistance
training of dorsiflexors on ankle joint range of motion in healthy subjects.

Methods

Poster presentations (PP)

PP-BN01 Biomechanics 1
Sixteen men participated in a training program in this study. They were randomly assigned to a training group (n=8) or to a control group (n=8). The training program consisted of either stretching and resistance training (combination program), or stretching only, which was allocated in the right or left leg at random. Before and 1, 2, 4, and 6 weeks after the onset of the training program, we measured active and passive ROM, and also measured ankle joint passive stiffness during passive dorsiflexion. We also measured the same parameters 1, 2, 4, and 6 weeks after the completion of the training program. To measure both active and passive ROM, the subjects were in supine position on a test bench, with the knee joint in full extension, and the goniometer was attached to the ankle joint. Subjects were asked to perform maximal dorsiflexion, beginning from the 30 degrees plantar flexion. Ankle joint passive stiffness was calculated based on the ankle joint angle – passive torque relationship.

Results and Discussion

In the combination program side, active ROM increased significantly after the onset of training 4 and 6-week (mean dorsiflexion angles (DF) were 20, 21, 23, 28, and 29 (deg), for pre, 1, 2, 4, and 6-week, respectively), and the training effect remained until detraining 4-week (mean DF: 27, 26, 26 (deg), and 24, 1, 2, 4, and 6-week, respectively) while in the stretching program side, active ROM did not change. Passive ROM increased significantly 2-weeks later and remained until detraining 4-week. This improved flexibility was associated with a decrease in ankle joint stiffness, especially in the dorsiflexion position. The results show that the 6-week program of static stretching is not sufficient to increase active ROM. However, only stretching would be effective to increase the passive ROM. We conclude that one should take into consideration the method to improve flexibility, based on the purpose (to increase active and/or passive ROM).

THREE-DIMENSIONAL ANALYSIS OF INTRACYCLE VELOCITY FLUCTUATIONS IN FRONT CRAWL SWIMMING

Psycharakis, S., Sanders, R.
Napier University, United Kingdom

The magnitude of velocity fluctuation (Vfluc) and the maximum (Vmax) and minimum instantaneous velocity (Vmin) during a stroke cycle (SC) have been linked to swimming performance. However, despite the multi-planar nature of swimming and the importance of the centre of mass (CM) calculation as a representation of body motion, two-dimensional methods and fixed points on the swimmers’ bodies have been used in the majority of studies. Moreover, changes in Vfluc have not been assessed during the course of an event or for any directions other than the swimming direction. The purpose of this study was to determine the three-dimensional methods, the magnitude of Vfluc, Vmax, Vmin of the CM during a 200m maximum front crawl swim and to examine whether they are associated with performance (as indicated by mean SC velocity (Vmean)).

Eleven male swimmers of national/international level performed a maximum 200m front crawl swim. Six stationary and synchronised cameras (four below and two above the water) recorded the performance at 50 Hz and four SCs were analysed (one for each 50m). Vmean, Vmax and Vmin (m/sec) in the swimming direction were obtained from the intracycle V data of the CM. Vfluc (m/sec) in each direction was calculated by subtracting Vmin from Vmax. The relative Vfluc/Vmax/Vmin were also calculated as a percentage of Vmean. Anthropometric data were calculated with the use of the elliptical zone method. Repeated measures analysis of variance and post hoc tests were performed to identify differences between SCs throughout the test, while pairs of variables were correlated to assess the nature and strength of relationships. Significance was accepted at p<.05.

Vmean generally decreased throughout the test. Vmax and Vmin were significantly higher in SCI than in other SCs (p=0.001) and had a high and positive correlation with performance (0.81 0.98, 0.001 8804, p=0.003). However, relative Vmax and Vmin were remarkably consistent during the 200m (110.8±0.4 % and 88.6±0.3 % respectively) and were not associated with performance. Vfluc and relative Vfluc in all directions did not change significantly during the test and, for the vast majority of SCs, were not associated with performance. Vfluc in the lateral and vertical directions were higher than in the swimming direction. Although Vmax and Vmin changed during the test and appeared to be good indicators of performance, no other variables were linked to performance or affected by technique deterioration. Considering that Vfluc is also influenced by resistive forces, which seem to have a non-linear relationship with V, the possibility of a non-linear relationship between Vfluc and performance could be examined in subsequent studies. Moreover, the large magnitude of Vfluc in the vertical and lateral directions suggested that future research needs to investigate more closely their causes and effects, especially for strokes with pronounced vertical movements such as butterfly and breast.
affected by the loading height. Therefore, pre-activation depends very little on the loading condition or type of jump performed. Pre-activation seems to represent a preprogrammed muscular activation functionally necessary for preparation of the landing in high level volleyball players (Reeser JC et al. However, sedentary group do not display the activation patterns that the high level volleyball players does.

MUSCULAR ACTIVITY OF KICKING LIMB DURING DIFFERENT KICKING TECHNIQUES IN SOCCER
Cerrah, A., Onarici Gunorg, E., Erhan, H. 
Anadolu University, Turkey
The kick is one of the most important skills in soccer and it is used for passing the ball or more often for scoring (1). The purpose of this study is to determine muscular activation patterns during different kinds of kicking techniques using electromyography (EMG) in soccer. First division soccer players have performed six different kicking techniques (side foot, lofted, inside curve, instep, outside and outside curve kicks) with one-step to a stationary ball towards a target 15 m away. Players have performed 3 maximum trials for each of the given techniques using the preferred leg. 45, 0, -45 approach angles have been used. Bipolar surface EMG activity of the rectus femoris (RF), vastus lateralis (VL), vastus medialis (VM), biceps femoris (BF) and gastrocnemius (GAS) muscles were recorded. The measurement sites were prepared and Ag/AgCl surface electrodes, filled with conductive electrolyte, were then positioned longitudinally along each muscle. Raw EMG records, 1-s before and after the ball contact were rectified, integrated and normalized. During back swing, there was a high activation of the BF in 6 kicking techniques and VL muscle had almost the same activation as BF in outside and side foot kick. GAS and VL were also active muscles during backswing whereas RF activity remained low and VM was slightly activated in all kicking techniques. The main forward swing was characterized by high activation of VL in all styles. VM and RF demonstrated their peaks just prior to ball impact during all kicking techniques. However VM has shown almost same activation in backswing and forward swing in side foot and outside kick. At impact time, BF and GAS become active whereas other muscles relaxed after contraction in forward swing in all kicking techniques. All muscles showed a gradual relaxation after impact in side foot, inside curve and outside curve kick. However all muscles demonstrated activation in lofted, instep and outside kick after impact. VL and GAS were the most active muscles during follow through.

The pattern of kicking is often described as a proximal-to-distal sequence of segmental movements (2). During the kicking motion, the foot rotates about both the medio-lateral (frontal) and longitudinal (vertical) axes of the body (3). So, the current study supports the earlier findings, which have been gathered via movement analysis techniques, from the muscular activation patterns aspect. However, it has not been clarified yet if there is any significant difference between high level and low/beginner soccer players.

A BIOMECHANICAL COMPARISON OF THE RUNNING GAIT OF MATURE AND YOUNG FEMALES
Lilley, K.
The University of Exeter, United Kingdom

Running has recently increased in popularity among both genders across all ages, and holds place as the leading sport of choice (Nova-check, 1998). Due to health benefits alongside social advantages, the numbers among one particular sub-group are expanding steadily, mature female runners (Vuori, 1998). However, the incidence of lower extremity injuries, specifically osteoarthritis, is vast among this group (Verbrugge, 2005). Despite this, current literature providing explanation for this injury prevalence is sparse. The purpose of this study was to quantify gait parameters of mature female runners, to assess whether certain running characteristics predispose to injury, specifically osteoarthritis. It was hypothesised that mature female runners would exhibit a gait pattern that differentiates them from younger runners, and that characteristics of their running gait would predispose this specific group to injuries such as osteoarthritis. 16 volunteer females (40-years) performed 10 running trials at 3.5m.s-1 ± 5% over a force platform. Knee dynamics including angles and moments during the stance phase of gait were identified through three-dimensional gait analyses. Comparisons with literature of young runners illustrated mature females to exhibit altered running patterns. High loading rates were demonstrated among the mature females (62.0 BW.s-1) when compared to a study involving females aged 24.4 years (23.3 BW.s-1) (Zifchock, Davis & Hamill, 2006). Additionally, high knee internal rotation angles (4.70 degrees), and large external adduction moments (1.06 Nm/kg) were exhibited by the mature females. Gait parameters have previously been associated with osteoarthritis including high loading rates, and knee internal rotation (Hawley, 2000; Johnson & Pedowitz, 2007). Additionally, knee external adductor moments are correlated with osteoarthritis development (Kaufman, Hughes, Morrey, Morrey & An, 2001). Therefore, the magnitudes characteristic of mature female runners in all three aforementioned variables may provide explanation for high injury rates among this group.

THE EFFECT OF CHANGES IN MUSCLE-TENDON UNIT LENGTH ON ACHILLES TENDON SHAPE

Iwanuma, S., Kurihara, T., Ikegawa, S., Fukunaga, T., Kawakami, Y.
Waseda University, Japan

Introduction
Controversy exists regarding extensibility of the Achilles tendon. Previous studies have only looked at lengthwise changes in the tendon, but some studies suggest transverse deformation of the aponeurosis by passive lengthening (Muraoka et al. 2003, Ilibis anterior muscle). The purpose of the present study was to investigate the effect of changes in muscle-tendon unit (MTU) length on the tendon shape (longitudinal and transverse) in vivo.

Methods
Eight healthy males (26±5yrs; 172±4cm; 69±7kg, mean±SD) were tested as subjects. With each subject in a supine position, a series of cross-sectional and longitudinal images of Achilles tendon (slice thickness 3mm, 0mm spacing) were obtained by MRI. The length, width and curvature of the tendon were determined from each image. The knee joint was fully extended and the ankle was kept in position of -15deg (dorsiflexed, DF), 0deg (neutral, AP), and 30deg (plantar flexed, PF). The tendon was divided into two portions (proximal and distal) at the distal end of the soleus muscle.

Results
The Achilles tendon length and width were identical for PF and AP positions, but its curvature was increased in PF. In DF position, the tendon length in DF increased by ~3mm (1.3%) and its width increased by ~3mm (7.6%) compared to AP. There was a difference between positions within the tendon: in the proximal portion it was not lengthened longitudinally but stretched transversely (7.6%), while in the distal portion it showed no significant transverse stretch but tended to elongate longitudinal (3.5%).

Discussion
The Achilles tendon shape in PF was similar to that in AP. Although previous reports indicated slackness in the tendon in a plantarflexed position (Muraoka et al. 2002), our results demonstrate that the tendon length does not change in PF. The tendon curvature, however, was different between AP and PF. In contrast, there was a significant difference in the tendon length between DF and AP. The length change of Achilles tendon was smaller than those of previous studies (Muraoka et al. 2002, De Monte et al. 2006). An increase in tendon width is contrary to previous findings (van Bavel et al. 1996, Muraoka et al. 2003). This discrepancy might be related to the difference of the target muscles, which needs further studies.

EMG AND KINEMATICS ANALYSIS OF THE PUSH UP EXERCISE: THE EFFECT OF HAND POSITIONS ON PRE-SELECTED MUSCLES

Marcolin, G., Paoli, A., Pacelli, F., Ippolito, D., Petrone, N.
University of Padova, Italy

The execution of push up exercise is useful to increase the strength of the upper body like chest, arms and shoulders as well as to evaluate the fitness level of a subject. Fitness literature reported that varying the hand positions during the push up can target specific upper body muscles. Previous studies investigated the effect of hand positions by a kinetic and electromyographical point of view ([1,2] considering triceps brachii and pectoralis major). Aim of the present work was to test the theory that hand position changes could induce different muscular recruitment by studying relationship between EMG activities and kinematics analysis. A six cameras stereophotogrammetric system (BTS-Italy) working at 60Hz was employed to record kinematics data. 30 reflective markers were placed on head (3), trunk (3), arms (8), hands (2), pelvis (2 at PSIS and 2 at ASIS), great trochanters (2), knees (4), ankles (2) and feet (2). The surface EMG activity of 12 muscles referred to the right side of each subject was recorded synchronously with kinematics by means of a PDA PocketEMG (BTS-Italy) at a sampling frequency of 1Khz. 5 hands position were chosen: hands at acromions width placed in front of the shoulders, hands 20cm over and hands 20cm below the shoulders, hands under the shoulders at 150% of acromions width and narrow hands base with right thumb and forefinger in touch with the left ones. Six subjects performed a set of 10 repetitions for each of the 5 hand positions with 3 minutes rest between sets. Kinematics data allowed to identify and quantify technical execution parameters as elbow angles displacement and velocity, angles between trunk and arms, time duration of eccentric and concentric phases and alignment between trunk and legs. One way ANOVA for each independent variable (muscle, hand position and phase of push up) was used to analyze differences in the iEMG signal. Differences in levels of muscular activity were assessed for statistical significance (p < 0.05) and then, if appropriate, a Tukey post hoc test was calculated. EMG and kinematics results indicated that hand positions influenced EMG activity of muscles analyzed in such a way that athletes and trainers should select different technical executions to induce a greater and more selective muscle activation.

EFFECT OF AGEING ON EQUILIBRIUM: LOWER POSTURAL STABILITY IS CORRELATED WITH GREATER TORQUES AT THE ANKLE LEVEL

Billot, M., Simonneau, E., Martin, A., Van Hoecke, J.
Laboratoire INSERM U887 Motricité-Plasticité, France

Background: Ageing is generally characterised by a decrease of force production. More particularly, Simonneau et al. (2007) reported a decline of agonist torques at the ankle joint in elderly adults. Ankle muscles are largely involved during equilibration process. It was previously observed a significant increase of Centre of pressure (CoP) displacement with ageing (Amiridis et al., 2003). However, the mechanical contribution of muscle around the ankle joint during postural task using the electromyographic (EMG) activity was unknown.
Thus, the aim of this study is to determine the mechanical contribution of triceps surae (TS) and tibialis anterior (TA) during various postural tasks in young and older adult. We hypothesis that the augmentation of the CoP displacement for older adults necessitates a more important cost in term of force.

Methods: Eight young adults (22.8 ± 2.4 years) were compared with seven older individuals (80.0 ± 4.2 years) during several postural tasks (Normal Quiet Stance (NQS), Romberg (ROM) and One Leg Balance (OLB)). CoP displacement was measured via a force platform during 10s for each condition. The Maximal voluntary contraction (MVC) was measured in two conditions (isometric dorsi- (DF) and plantar-flexion (PF)) via an isokinetic dynamometer. The EMG activity of TS and TA muscles were recorded simultaneously. To determine the EMG / isometric torque relationship, some sub-maximal contractions were produced in randomized order at 5, 10, 20 and 30 % of the MVC in the DF and PF conditions.

Results: Ageing induces an increase of the CoP displacement in the two most complex postural tasks i.e. ROM +38 %, p < 0.05 and OLB +86 %, p < 0.001. A significant decrease in the DF (~ -36 %) and PF (~ -32 %) agonist torques was also observed with ageing (p < 0.01). Excepted NQS, we showed a significant increase of relative torque developed by the both TS and TA muscles for older than young adults in ROM (15 ± 5.1 % vs. 26 ± 4.9 % for YG and OG respectively, p < 0.01) and OLB (23.7 ± 6.1 % vs. 41.9 ± 7.8 % for YG and OG respectively, p < 0.001).

Discussion: Our study showed that ageing induces an increase of the CoP displacement with increment of the postural tasks complexity (Amiridis et al., 2003). Furthermore, a significant decrease of the TS and TA agonist torques was observed for older adults. Moreover, an augmentation of the CoP displacement was accompanied by an increment of torque and RMS of muscles around the ankle for the elderly individuals. Greater torques and RMS activity generated at the ankle level while standing could induce fatigue more rapidly and higher risk of fall.

COMPARISONS OF PLANTAR PRESSURES BETWEEN OBESE AND NON OBESE POSTMENOPAUSAL WOMEN

Monteiro, M., Gabriel, R., Moreira, M., Maia, M., Freitas, J.
University of Trás-os-Montes e Alto Douro, Portugal

The analysis of the influence of fat mass in the plantar pressure turns out to be important given that the persistent overload in the musculo-skeletal system endangers the individual’s mobility and predisposes him to adapt it in a pathological way, increasing the risk of articular injury. The aim of this study was to determine the differences in plantar pressure parameters (peak pressure and absolute impulse) between obese and non obese postmenopausal women.

Subjects included 59 postmenopausal Caucasian women (age, 56.61 (5.81) years old; BMI, 28.3 (3.68) kg/m2), 48 of which were obese (BMI > 25.5 kg/m2) [1]. The Whole-body adiposity was measured by the BMI (weight/height2) and the subjects were evaluated with a footscan pressure plate (RsScan International, 1m*0.4m, 8192 sensors, 250 Hz) with the Footscan software 7.2, walking barefoot in a natural cadence. Mann-Whitney U was used to compare the plantar pressure variables between obese and non obese postmenopausal women.

The obese postmenopausal women presented higher peak pressure values compared to the non obese group in the Metatarsal 4 (p=0.02), Midfoot (p=0.03), Medial Heel (p=0.04) and Lateral Heel (p=0.01). The same group also showed higher absolute impulses in the Metatarsal 1 (p=0.04), Metatarsal 4 (p=0.01) and Midfoot (p=0.02).

Inversely to previous publications [2, 3] where higher plantar pressure was located at the Forefoot level, our data suggest that postmenopausal obese women have higher peak pressure values in the Midfoot and Rearfoot during the walking. However we found higher values of absolute impulse in the forefoot and Midfoot. Therefore we can conclude that in obese postmenopausal women the Metatarsal 4 and the Midfoot are the most overloaded areas, comparing to the non obese women.

INFLUENCE OF GENDER AND FATIGUE ON KNEE JOINT CONTROL LANDING STRATEGIES

Gehring, D., Melnyk, M., Gallhofer, A.
University of Freiburg, Germany

Gender and fatigue are discussed to affect the anterior cruciate ligament (ACL) injury risk. In recent years, the influence of these factors on the knee joint control during critical movements is under discussion. The purpose of this study was to investigate kinematics, kinetics, and active muscle control strategies of the knee joint across gender and fatigue conditions. Nine females and thirteen males performed two-legged landings before and after a fatigue protocol. Knee joint kinematics and vertical ground reaction forces were measured as well as electromyography of the quadriceps, hamstring and gastrocnemius muscles prior and after ground contact. In general, females landed with increased knee flexion velocities and knee joint abduction angles. Compared to males they also showed different muscle activation patterns such as a delayed activation of the lateral hamstring and the m. vastus lateralis in the preparatory phase of the landing. Fatigue led to a reduced pre-activation of the medial and lateral hamstrings and the gastrocnemius muscle both in males and females, whereas the knee joint kinematics in the early phase of the landing was not altered. The gender differences in knee flexion velocity, maximum abduction angle, and muscle activation order suggest that females and males have different strategies and abilities to control the knee joint during dynamic landing movements. These differences as well as the decreased hamstring and gastrocnemius muscle activity due to fatigue provide evidence for an increased ACL loading in females and in fatigued condition.

FUNCTIONAL PRINCIPAL COMPONENT ANALYSIS (F-PCA) FOR THE CHARACTERIZATION OF INDIVIDUAL RACE WALKING PERFORMANCE STRATEGIES

Donà, G., Pretoni, E., Rodano, R., Cobelli, C.
University of Padova, Italy

Introduction
The main task for coaches is to identify and carry out training programs that could determine the athlete's improvement. Therefore, the depiction of athletes' motor behaviours and of their changes over time is needed. The problem of capturing the athlete's actual state is
strongly affected by the presence of motor variability, which occurs not only between but also within individuals (1). Hence, significant information contained in the data has to be summarized and interpreted. Namely, the most representative features of the individual have to be recognized and separated from noise. Conventional data analysis techniques lack in extracting and synthesizing significant information from a large amount of variables. In contrast, multivariate statistical analysis has proved to be a powerful tool to eliminate collinearity, by presenting only the essential structures of data. In particular, functional principal component analysis (f-PCA) has been shown to be effective in the evaluation of human motion. The purpose of this paper was to investigate the use of f-PCA in sports science, for reducing and interpreting data, while accounting for their original variability.

**Methods**

An 8-camera optoelectronic motion analysis system (ELITE2002, BTS, Milan, Italy) and a force plate (AMTI OR-6-1000, Watertown, USA) were used to collect and estimate kinematics and kinetics of seven race walkers (19.7±2.1 y; 1.75±0.10 m; 58.3±8.3 kg) of international level. After a standard 20 minutes warm up routine, each subject was asked to race walk across a 15m walkway. Several (N=20) race walking repetitions were acquired and kinematic and kinetic variables (lower limb angles, GRF, joint moments and powers) were processed. f-PCA2 was applied to data, in order to compare athletes according to their skill level.

**Results**

A general biomechanical description of race walking biomechanics was pursued, in order to get a full comprehension of the movement under analysis. The first four principal components explained more than 95% of data variability for most of the variables. A biomechanical interpretation of functional components allowed a robust and complete characterization of each athlete’s performance strategy. Race walkers of the same skill level were characterized by similar loads on the functional principal components.

**Discussion**

This study showed that functional principal component analysis is an innovative tool for individual motor skills characterization. It could help coaches in designing personalized training programs, by evidencing individual abilities or deficiencies.

**CHANGES IN SPONTANEOUS BREATH VOLUME AND INTRA-ABDOMINAL PRESSURE DURING DIFFERENT LOAD LIFTING**

Kawabata, M., Shima, N., Nishizono, H.

National Institute of Fitness and Sports in Kanoya, Japan

**Introduction:** Intra-abdominal pressure (IAP) is increased to stabilize lumbar spine during lifting (Hernborg et al., 1985). It is known that development of IAP was influenced by breath volume, for instance, development of IAP tends to be elevated highly when the breath is inhaled before lifting and held during lifting (Hagins et al., 2006). However, it is unknown whether spontaneous breath and development of IAP change according to different load lifting. The purpose of the present study was to examine changes in spontaneous breath and development of IAP during isometric lifting. Methods: Eleven men (22±2years) were postured bending the trunk forward and extending knee joint, and performed isometric lifting tasks using a lifting device attached force transducer at 30%, 45%, 60%, 75%, 90%, 100% of maximal effort each three times at random. Subjects were experienced to lift on each load before actual measurements. IAP was measured using a pneumotachometer attached to a face mask (FM-200, Arco system). The inspiratory volume before just lift-off and expiratory volume just after lift-off were normalized to tidal volume at rest. The development of IAP during lifting was normalized to the maximal IAP obtained during the Valsalva maneuver (%IAP). Subjects were secreted of breathing information to avoid intentional breathing. The significant changes of variables of respiratory volume from tidal volume and development of IAP from IAP at rest on lifting posture were assessed with repeated measures ANOVAs with post hoc Dunnell’s tests (p<0.05). Results: The inspiratory volume significantly increased and expiratory volume significantly decreased in the load magnitude of lifting above 45% and 50% of maximal effort lifting, respectively. During 30% 100% of maximal effort lifting, normalized inspiratory volume was increased to 111.7±16.6%, 143.5±15.5%, 161.1±15.4%, 191.9±19.6%, 206.8±15.2%, 235.7±20.8% respectively, and normalized expiratory volume was decreased to 50.7±12.7%, 27.6±9.9%, 18.2±7.7%, 13.2±6.3%, 7.2±2.1%, 5.1±1.3% respectively (mean±SE). The development of %IAP significantly increased to 13.1±1.8%, 25.2±2.6%, 36.0±3.1%, 51.9±2.8%, 68.8±4.6%, 77.0±4.4% respectively. Conclusion: The spontaneous respiratory volume and development of IAP changed regularly in proportion to the load magnitude of isometric lifting. It is suggested that these changes would be maneuvers to obtain lumbar spine stability based on preprogramming of the central nervous system.

**ANALYSIS OF COVERED DISTANCE AND VELOCITY OF INDOOR BLIND SOCCER PLAYERS OBTAINED WITH AN AUTOMATIC TRACKING METHOD**

Marche, A., Ziskind, F., Misuta, M., Cunha, A., Barros, R.

Campinas State University, Brazil

Nowadays blind soccer is practiced in 21 countries and its first event in a Paralympics Games was in Athens (2004). However, scientific research information on this modality is rare in literature, mainly studies about player movement in the court during official games. For this reason, many physical trainers might make mistakes on prescribing physical training to their athletes since there is no study characterizing the requirements of such modality. Then, the aim of this study was to analyze the covered distance and velocities ranges of indoor blind soccer players (excluding goalkeepers) in an official competition. For this study was filmed the final game of indoor soccer of 3rd ISBA Championship and Games 2007. The data acquisition used four digital cameras (30 Hz) standing in the highest bleachers. Each camera recorded one region of the court, in the way of covering the whole court. In this study it was used the Divideo system [I] for automatic tracking of players trajectories through videogrammetry aiming at obtaining data as function of time about players positioning. The data were reconstructed in 2D and afterwards they were smoothed by the digital filter Butterworth of 3rd order, which a cut frequency of 0.4 Hz at Matlab software. The mean covered distances of the players were calculated for the first and second halves and two runoff halves. In case of substitution, it was considered the total distance covered of all players involved. First half: 2275.8 m, Second half: 2289.6 m, First half of runoff: 1034.2 m; second half of runoff: 1067.0 m. A one-sided paired t-test (p<0.05) was performed to verify if the mean distances covered in the first half of the game were greater than in the second half. The t-test result showed that the covered distance in the first and second halves were significantly different (p=0.045). The velocity data were divided into six ranges of velocity: 0-0.72 km/h (standing), 0.72-1.1 km/h (walking and jogging), 1.14-14 km/h (low speed running), 14.19 km/h (moderate-speed running), 19-23 km/h (high-speed running), more than 23 km/h (spinning), and results are presented as the mean of covered distance of all players in Marche, A., Ziskind, F., Misuta, M., Cunha, A., Barros, R.
each velocity range, respectively. First half: 30.64 m, 1737.06 m, 243.74 m, 180.19 m, 20.32 m, 2.11 m. Second half: 64.23 m, 1927.97 m, 220.42 m, 110.13 m, 8.38 m. 0 m. First half of runoff: 16.02 m, 803.3 m, 118.13 m, 82.28 m, 11.29 m, 1.32 m. Second half of runoff: 193.63 m, 761.90 m, 34.5 m, 15.78 m, 3.13 m, 0.18 m. The covered distances and velocities that were obtained in an official competition presented in this paper could be useful for physical trainers to prescribe more specific training activities.

WHAT IS THE BEST PARAMETER TO QUANTIFY SHOCKS DURING HEEL-TOE RUNNING?

Samozino, P., Morin, J.B., Mermet, V., Barla, C., Oullion, R., Baly, L., Belli, A.
UR Physiologie et Physiopathologie de l’Exercice et Handicap, Université de Saint-Étienne, Médecine du sport et Myologie - CHU Bellevue, 42055 Saint-Étienne Cedex 02, France.

Repetitive heel-strikes occurring during running have been associated with musculoskeletal injuries (Nigg et al. 1995). Quantifying the impact severity is particularly important for shoe manufacturers wishing to attenuate shocks by cushioning. Different mechanical parameters have been used to quantify heel-strike intensity at impact (Cavanagh 1990). The most common are vertical peak impact force and corresponding loading rate, peak shank accelerations and shock wave propagation speed. However, heel-strike comparisons may differ depending on the parameters used (De Wit et al. 1995), and what is more, for some of these parameters (e.g. peak impact force value), results are contradictory between studies (De Wit et al. 1995, Dickinson et al. 1985). Our aim was to determine, among these various parameters, the one(s) allowing to distinguish heel-strike shock intensity at best between different running conditions.

Thirteen physically active men ran at 3.33 m.s⁻¹ in 8 randomised 5-min conditions inducing various levels of shock intensity: reference condition (freely chosen stride frequency and neutral shoes), barefooted, with soft and hard midsole shoes, with +20% and -20% stride frequency, and with +20% and -20% vertical loading. Vertical ground reaction force and shank accelerations were measured (1000 Hz) on a treadmill dynamometer (HEF Techmachine, France) and using a uniaxial skin-mounted accelerometer (Analog Devices, USA), respectively. Peak impact force (Fz1 in N), time to Fz1 (TFz1 in s), impact loading rate (Rz1 in N.s⁻¹), peak shank acceleration (AS in m.s⁻²) and time to AS (TAs in s) were calculated for each step and averaged over twenty consecutive right steps during the last minute of each condition.

The shock wave speed propagation (SP in m.s⁻¹) was obtained as the ratio of the heel-accelerometer distance to TAs.

ANOVA for repeated measures and Newman-Keuls post-hoc tests, performed for each factor (midsole hardness, stride frequency, body weight), put forward that Fz1 and Rz1 were the parameters showing the highest number of significant differences throughout the proposed running conditions (11 and 8 out of 12 possible differences, respectively). Sensitivity analysis showed important changes in Rz1, SP, TFz1 and TAs with midsole hardness variations, in Rz1 and AS with stride frequency variations, and in Rz1, AS and TFz1 with body weight variations. In light of these results, Rz1 can be considered as the most discriminating mechanical parameter to distinguish heel-strike shocks intensity at best during running. In contrast, Fz1 and AS, widely used in running impact studies, were only slightly influenced by the midsole hardness.

EMG ANALYSIS OF THE OF DELTOIDEUS ACTION DURING FRONT CRAWL SWIMMING ARM RECOVERY USING DIFFERENT NORMALIZATION PROCEDURES

*Faculty of Sport, Porto University, Portugal. **State University of Santa Catarina, Florianópolis, Brazil, Portugal

The electromyography (EMG) normalization process is a fundamental task to be accomplish when comparing EMG signals between muscles, subjects, or even testing sessions. Some studies tried to compare the differences between alternative methods (Burden et al., 2003) but none was carried out in real sport context, specially swimming.

The purpose of this study was to compare the data obtained from two different types of normalization procedures of the Deltoideus muscle (posterior, middle and anterior portions) EMG during the arm recovery phase in front crawl swimming.

A national level male swimmer (24 years old, 68.5 kg, 172.9 cm and 15 years of competitive experience) performed a protocol of 10 x 25 m at 200 m front crawl race pace, for surface differential EMG activity assessment (five repetitions were performed with lateral arm recovery and five repetitions with bend arm recovery). The decomposition of the arm recovery phase into its characteristic sub-phases was performed through qualitative analysis of video records, synchronized with the EMG signals by a light-trigger.

After standard cleaning and shaving procedures, the electrodes were fixed with adhesive tapes, plastic films and silver tape on the epidemnic surface projection of the muscles. The EMG signals were normalized to maximum isometric voluntary contraction (MVC) and to dynamic peak (DP). Independent sample t-test and Anova were used to compare the different types of normalization. Statistical significance was set at p<0.05.

For both recovery patterns, in the middle and anterior portion of Deltoideus, it were found higher values when MVC was used has the normalization parameter. In the comparison between the two types of arm recovery, bend and lateral types, it were found differences in the posterior and middle portions of the Deltoideus muscle when data were normalized to MVC, but no differences were found when normalization with DP value was used. This analysis also allowed the recognition of differences among the sub-phases of the two recovery patterns when normalized to MVC and to DP. The posterior portion, that was the less active during the two types of recovery patterns when normalized to MVC, tended to be the most active when DP was used for normalization.

It is concluded that the EMG analysis procedures of Deltoideus muscle during front crawl swimming is influenced by the type of normalization used, which can lead to miss understandings of the real actions and muscle participation on dynamic sport movements.

References.
Electromyography (EMG) has been used in swimming to describe and analyse muscle participation in swimming technique. However, studies aiming to observe the implications of the different variants of a specific swimming arm or leg action are scarce. The purpose of this study was to analyse the superior, middle and inferior portions of the Trapezius muscle in the lateral (LRP) and bend (BRP) arm recovery patterns in front crawl, taking into account the occurrence of breathing and non-breathing cycles (BC and NBC, respectively).

A trained male swimmer performed a front crawl protocol of 10 x 25 m at 200 m race pace, alternating the LRP and BRP. Active differential electrodes were positioned according standards after skin shaving and cleaning, and fixed with adhesive tapes. The EMG-data were assessed by a surface EMG system developed for aquatic use (Gonçalves et al., 2006), with a sample frequency of 1000 Hz and subsequent emission to an external receiver and an analogical/digital conversion plate that allowed the download of the signal to a PC for following assessment by a surface EMG system developed for aquatic use (Gonçalves et al., 2006), with a sample frequency of 1000 Hz and subsequent processing.

The only significant differences were found for the EMG intensity (%MVC) of the superior portion of the Trapezius muscle. In this variable it was possible to observe higher values for the BRP compared with the LRP when BC were considered. The swimmer also achieved higher values of EMG intensity (%MVC) of the superior portion of Trapezius muscle during the NBC compared with the BC, both during BRP and LRP. Both effects may be explained considering the main function of this portion of the muscle - the elevation of the scapula - which is very important in both recovery patterns and in breathing or non-breathing cycles, but mostly required in the BRP and in the NBC due to the higher hand/water proximity.

For NBC no significant differences were found between recovery patterns for any of the studied variables. Non significant differences were obtained for any of the comparisons conducted for the middle and inferior portions of the muscle, and also for the superior portion when AT and iEMG results were considered. It is concluded that, based on the evidence provided in this pilot study, there are not a better pattern of arm recovery in what muscular activity is concerned.

**ANGULAR KINEMATICS OF HIGH LEVEL LONG JUMPERS IN COMPETITION**

Lara, J., Sakalauskas, C., Prudêncio, M., Mercadante, L., Cunha, S., Russomanno, T., Misuta, M., Barros, R.

I-Campinas State University; 2-Mogi das Cruzes, Brazil

The aim of this study was to analyze angular kinematics of high level long jumpers in competition. The data were collected in the GOLD MEETING RIO OF ATHLETICS 2007, a competition included in the calendar of the International Association of Athletics Federation (IAAF).

Seventeen jumps of nine male athletes ranging from 7.26m to 8.53m were analyzed. The winner of this competition was also the 2007 world champion in the modality (8.57m). Two digital video cameras (60 Hz) positioned inside the field along the runway were used to reconstruct the movement from the last touch-down to the takeoff (support phase). The DVideo system was used for the 3D kinematical analysis (Figueura et al., 2003). Eighteen anatomical landmarks were manually digitized throughout both video sequences. The body was represented according to the model of ten segments proposed by Zatsiorsky (1989). The data were filtered with a zero-phase forward and inverse Butterworth digital filter of 3rd order with a 6 Hz cut-off frequency. Using the 3D coordinates the following joint angles were calculated: neck, trunk, shoulders, elbows, hips, knees and ankles. Three ways of analyses were applied to the joint angles during the support phase. 1) The graphical analysis of mean (+SD) curves in function of the percent of the support phase. 2) The average of maximal angles of knee flexion and ankle dorsi-flexion during the support phase. Analyses 1 and 2 were performed in order to characterize the angular motion patterns of the jumpers in this competition. 3) The last analysis consisted of a t-test of the percents of the support phase in which occurred the peaks of knee flexion and dorsi-flexion of the support limb. The results were 1) curves of the central tendency and variability for all angles. 2) The average maximum knee flexion (+SD) and ankle dorsi-flexion angles of the support limb were (37.8°±6.8°) and (8.3°±5.3°) and to the swing limb were (138.5°±9.0°) and (38.4°±6.6°). 3) Statistical differences (P<0.05) were verified comparing the mean maximal knee flexion percent (46.2±8.2%) and the mean maximal ankle dorsi-flexion percent (53.1±7.3%).

In this study provided an useful description and analysis of a high level long jumpers in competition.

**ADDED MASS IN HUMAN SWIMMERS: AGE AND GENDER DIFFERENCES**

Caspersen, C., Berthelsen, P., Eik, M., Pâkozdi, C., Kjendlie, P.

Norwegian School of Sport Sciences, Norway

INTRODUCTION: In unstationary swimming (changing velocity), some of the water around the swimmer is set in motion. This can be thought of as an added mass (AM) of water. Previously only one other study (Klauck, 1999) has investigated added mass on swimmers during passive gliding, and reported added mass values in a range of 30-70kg. The purpose of this study was to find added mass on human swimmers and the effects of age and genders on added mass.

METHODS: 31 subjects between the ages of 12 to 36 years were included. They were recruited into three groups, boys (aged 13.7±1.1years), women (21.8±3.4years) and men (25.2±4.9years) with body mass of 52.6±10.6kg, 63.9±5.3kg and 78.2±6.3kg, respectively. The subjects were connected to a 2.8m long bar with handles, attached with springs (stiffness k=318N/m) and a force cell. By...
oscillating this system vertically and registering the period of oscillations it was possible to find the added mass of the swimmer, given the known masses of the bar and swimmer.

RESULTS: Added mass for the three groups were 14.5±3.1 kg, 15±1.2 kg and 21.1±2.5 kg for boys, women and men, respectively. This corresponds to relative added mass (AM%) of, respectively 27.8±2.9%, 23.6±1.5% and 27±2.2% of the subjects' body mass. This study reported significant difference in AM (p<0.01) and AM% (p<0.01) between men and women. In boys and men significant differences were found for AM (p<0.01), but not for AM% (p>0.01).

DISCUSSION: The added mass in this study seems to be lower and within a smaller range than previously reported (Klauck, 1999). An added mass of about 27% of body mass will influence inertial forces during passive gliding phases in a swimming race, but must also be considered in intracyclic velocity fluctuations. The subjects’ lack of experience to hold the optimal and best position on the bar during oscillation, could lead to increased AM. Boys and men reported similar values for AM%. This indicates that AM is in some way dependent on body mass. Lower AM% values for women could mean that they are influenced by other effects of body size such as height, CD, frontal surface area or % body fat compared men. This study indicates an effect of gender between men and women, but no effect on AM by age between boys and men. If age can be viewed to represent experiences [and skill], added mass seem not to be reduced by swimming training or skill enhancement.

VALIDITY OF A VELOCITY DECAY METHOD FOR ESTIMATING PASSIVE DRAG IN SWIMMERS

Eik, M., Berthelsen, P., Caspersen, C., Pâkozdi, C., Kjendlie, P.
Norwegian School of Sport Sciences, Norway

INTRODUCTION: Passive drag can be measured by towing swimmers passively through the water. This requires expensive and often inaccessible equipment and can be a time consuming process. The velocity decay test has previously been used as an indirect method for estimating passive drag (Kjendlie & Stallman, 2008). The aim of this study was to test the validity of the velocity decay method by comparing the passive drag coefficient (D) calculated from the velocity decay test with D from towing tests. To estimate passive drag from the decelerating phase correctly, the added mass effect was taken into account.

METHODS: 24 subjects (6 women, 9 boys and 9 men) performed the velocity decay test twice on the same day. They were all familiar with the testing procedures. A rotating wheel. The swim-meter counts the rotations and thereby calculates the instantaneous velocity over the decay period. The added mass effect was taken into account by adding 27 % to the body weight in the calculations.

RESULTS: The oscillation decay test resulted in an average added mass of 26.3 (2.9%) of body weight. The average D values from the velocity decay test and towing tests were 24.4 and 18.1, respectively. A paired t-test revealed a statistically significant difference in D values calculated from the towing procedure and estimated from the velocity decay method (t=5.27 and p<0.01).

DISCUSSION: The added mass in this study seems to be lower and within a smaller range than previously reported (Klauck, 1999). An added mass of about 27% of body mass will influence inertial forces during passive gliding phases in a swimming race, but must also be considered in intracyclic velocity fluctuations.

RELIABILITY OF A VELOCITY DECAY METHOD FOR ESTIMATING PASSIVE DRAG IN SWIMMERS

Eik, M., Aspenes, S., Berthelsen, P., Caspersen, C., Pâkozdi, C., Kjendlie, P.
Norwegian School of Sport Sciences, Norway

INTRODUCTION: Observing the velocity decay after swimmers push off from the wall has previously been used as an indirect method for estimating passive drag (Kjendlie & Stallman, 2008). This method is based on the assumption that when a swimmer slides passively through the water, the water resistance is the only force retarding the swimmer and causing the velocity decay. The aim of this study was to test the reliability of the velocity decay method by measuring the consistency of the data from repeated tests under the same conditions.

METHODS: 21 trained swimmers aged 16.4±2.0 performed the velocity decay test twice on the same day. They were all familiar with the method due to previous testing. In prone position with arms above their head, the subjects pushed off from the wall before passively gliding to a stop. The gliding velocity decay was measured. A Matlab routine seeking the least sum of squares was run through the velocity data, v(t), and estimated the highest velocity immediately after push off (v0) and passive drag coefficient (D) from: v(t) = v0 / ((Dv0t/mv) +1), where mv is the virtual mass [the sum of the mass of the subject and the added mass]. Mean D values from the five towing velocities and D values estimated from the velocity decay test were compared by a paired t-test.

RESULTS: The oscillation decay test resulted in an average added mass of 26.3 (2.9%) of body weight. The average D values from the velocity decay test and towing tests were 24.4 and 18.1, respectively. A paired t-test revealed a statistically significant difference in D values calculated from the towing procedure and estimated from the velocity decay method (t=5.27 and p<0.01).

DISCUSSION: The added mass in this study seems to be lower and within a smaller range than previously reported (Klauck, 1999). An added mass of about 27% of body mass will influence inertial forces during passive gliding phases in a swimming race, but must also be considered in intracyclic velocity fluctuations.

REFERENCES
through with experienced swimmers. Results from an unpublished study with students (non-swimmers) performing two velocity decay tests showed less reliability (cronbach’s alpha=0.889, \( t=-2.12 \), p=0.089) and average difference from the mean =14.1%.

ACCURACY OF A NOVEL THREE-DIMENSIONAL UNDERWATER KINEMATIC ANALYSIS SYSTEM

Silvatti, A., Sarro, K., Barros, R.
Campinas State University – Campinas, Brazil

This work aimed to analyze the accuracy in a novel three-dimensional underwater kinematic analysis system. The system consisted of up to five Basler cameras (k602A) enclosed in housings specially designed and connected to a single desktop PC for online data acquisition. Software interfaces were developed for acquisition, camera controls, measurements and three-dimensional reconstruction starting from a previously proposed system Dvideo (Figueroa, et al. 2003). The reconstruction accuracy was determined in two tests, both out of the water and underwater. Four cameras were used (50 Hz) to record the images, positioned up and down at the right and left side. In the first test, the accuracy was determined by calculating the root mean square (RMS) for the reconstruction of nine points with known coordinates. For the second test, a rigid body with four black markers (2.5 mm) fixed on it was used. The rigid body was moved in front of the system out and underwater. The accuracy in this test was defined by the mean absolute errors (MAE) obtained from the curves of distances between markers obtained in function of time from their three-dimensional coordinates. The RMS error values obtained out of the water (2.4mm ±0.03) and underwater (2.9mm ±0.0) were similar and they were lower than the values found in (Gourgoulis, et al., 2008) (4.6±0.5 out of water, 5.9 ±1.5 underwater). The results regarding the two distances between markers out of the water and underwater were compared using a robust estimate of uncertainties in relation to the medians with 5% level of significance. The results revealed no significant differences among the distances calculated out (median=273.8) and underwater (median=276.4mm). The absolute mean error was 1.0mm out of the water and 2.8mm underwater, which are in accordance to the values found in literature (from 0.5mm to 11.6mm) (Chiari, et al. 2005). The results showed the reliability of the system for the underwater three-dimensional kinematic analysis.

THE SIGNIFICANT EFFECT OF APONEUROSIS ON TISSUE STAIN AMONG TRICEPS SUARAE MUSCLES DURING ECCENTRIC CONTRACTION

Oda, T., Hirano, R., Chino, K., Kanehisa, H., Fukunaga, T., Kawakami, Y.
RIKEN, Japan

INTRODUCTION: It has been recognized that amplitude of induced tissue damage in both muscle and tendinous (tendon + aponeurosis) tissues is a function of experienced lengthening strain. The objective of the present study was to investigate the effect of existence of aponeurosis on tissue strain among triceps surae muscles during eccentric (lengthening) contraction with computer simulation. We hypothesized that aponeurosis influences considerably to magnitude and distribution of tissue strain in contracting muscles. METHODS. A large deformation non-linear finite element analysis was used. A hexahedral constitutive mesh model of triceps surae muscles, with muscle, aponeurosis and tendon tissues, was constructed based on cross-sectional MR images. As mechanical parameters, Young's modulus and Poisson's ratio of each tissue during maximal eccentric contraction were estimated from our experimental data and previous reports. Then, two settings, with and without aponeurosis were prepared: 1) normal model with aponeurosis (AP) and 2) model in which the mechanical properties of aponeurosis in AP converted into that of muscles' (NAP). Anatomical origins of muscles were fully fixed as a boundary condition. A 10mm lengthening was applied to simulate eccentric contraction by displacing the end point of Achilles tendon. RESULTS AND DISCUSSION: In AP, the first principal strain (FPST) by 10.3% was concentrated on the portion with smallest cross-sectional area in Achilles tendon. Muscle tissues in distal portion of soleus muscle (SOL) and around muscle-tendon junction between Achilles tendon and SOL (MTJ) experienced 4.0% and 4.9% FPST, respectively. FPST in proximal muscle tissues of both SOL and gastrocnemius muscle was less than 3.0%. In NAP, on the other hand, FPST was concentrated on muscle tissues around MTJ by 22.3%. FPST was slightly larger than that of AP for muscle tissues in distal portion of SOL (6.4%), but smaller for the tendon tissues with smallest cross-sectional area in Achilles tendon (11%). These results indicate that the existence of aponeurosis could reduce the experienced strain among muscle tissues, especially around MTJ. This suggests the role of aponeurosis in the reduction of muscle damage by decreasing the amplitude and distribution of sizable strains in muscle tissues. Moreover, it is considered that reduction of muscle belly elongation by the existence of aponeurosis could result in large Achilles tendon elongation in AP, implying high risk for tendon tissue damage but possibility that aponeurosis enables Achilles tendon to storage effectively its elastic energy. CONCLUSION: The present study demonstrated the significant effect of aponeurosis on tissue stain among triceps surae muscles during eccentric contraction. Aponeurosis in triceps surae muscles would have functional significance for 1) decrement of muscle tissue damage and 2) effective storage of elastic energy in tendon tissues.
Introduction. Activity of the motor cortex in one hemisphere reduces the maximum motor outflow of homologous parts of the contra-lateral hemisphere, resulting in a reduction in the maximum torque a muscle can produce when the contralateral homologous muscle is activated simultaneously. If this statement is true, then bilateral deficit (BLD) should exist during voluntary isometric contraction. However, if the BLD is caused by the inhibition in the motor cortex, BLD cannot exist during eccentric contraction, because the force enhancement due to muscle stretch caused by the increasing resistance of the passive elastic element and/or the stretch reflex. The aim of this study was to test this hypothesis.

Methods. Six physically active males were recruited in this study. The subjects were seated in a computerized dynamometer (MultiCont II) and were instructed to perform isometric and eccentric contractions with the knee extensor muscles. Unilateral (UL) and bilateral (BL) knee extensions were carried out randomly. Maximum isometric torque (MIT) was measured at 60 and 90 degrees of joint angle. The eccentric contraction started at 60 degrees and terminated at 90 degrees using 30 degrees/s or 300 degrees/s constant velocity. Maximum torque enhancement (MTE) was determined from torque-time curves. Percentile ratio was calculated dividing the summed torque of left and right knee extensors produced in UL and BL contractions. Mean and SD was calculated and the means were compared by using independent Students t-test.

Results. MIT was 13.8 % lower during BL as compared with UL at 60 degrees, on the contrary at 90 degrees MIT was 10.6 % greater during BL than during UL. The percentile ratio of BL/UL was 87.9 % and 108.9 %, respectively. MTE was 3.1 % and 3.3 % greater for BL as compared with UL applying 30 degrees/s or 300 degrees/s velocity, respectively. The ratio of maximum eccentric and isometric torque ranged between 1.23 and 1.58 when the knee was flexed with 30 degrees/s velocity. The ratio was greater when 300 degrees/s velocity was applied (1.36 and 1.79). The BL/UL percentile ratio was significantly greater during isometric than during eccentric contraction.

Discussion. Our results are somehow controversial. We found bilateral deficit during isometric contraction measured maximum torque at 60 degrees of knee joint angle that may strengthen the idea that BLD can be attributed to the reduced neural drive originated from motor cortex. We hypothesized that if there is no BLD during eccentric contraction then it indirectly supports the idea that BLD caused by the disturbances between the motor cortex of the homologous muscles at the two hemispheres. We found no BLD during eccentric contraction that could prove our hypothesis. However, the bilateral facilitation during isometric contraction at 90 degrees does not allow us to draw this conclusion. It is difficult to explain why the motor cortices affect each other with different way at different joint a
Ten elite male kayak paddlers, all members of the Portuguese sprint team, volunteered for the study (age 22.0±3.2 yrs, height 177.1±5.8 cm, mass 77.7±5.4 kg). Written informed consent was obtained from each subject. All subjects were required to perform two trials, using each a type of seat (RS and SS), which were conducted in random order (7 d apart). A maximal incremental test, with five steps, was conducted in each trial, for this analysis we analysed the 1st, 3rd and 5th steps. The test steps work load was calculated based on the mean power of a 4 min maximal test performed on the KE prior to the beginning of the study. All trials were conducted on a calibrated KE (Dansprint). Five complete cycles were analysed. The cycle was divided by two paddle positions: immersion and water exit (phase I) and water exit and immersion (phase II) (Begon et al. 2003). In each trial the kinematics data (phases duration, entry and exit 2D shaft angle) were recorded by two synchronized cameras.

Amplified at 25Hz. Nine marks (7 anatomic and 2 on paddle) were digitised using the AnaMovH system. The DLT method was used to convert digitised points to real 2D coordinates. A low pass Butterworth filter at 12Hz-4th order was used to smooth data. The percentage variance accounted (VAF) was computed as the normalized error between the paddle path using different seats. Differences in dependent variables between trials were analysed for statistical significance with paired samples Student's T-test (p<.05).

Results/Discussion

When compared the phases duration, entry and exit 2D shaft angle between the RS and SS, no statistical significant differences were found (p<.05). The horizontal paddle path was significantly different between conditions (RS and SS) for the three steps of the test, but it was at high intensity (5th step) where higher differences were found (p<.01).

Conclusion

The results suggest that the RS brought some modifications on paddling technique on KE, further research is required to fully understand this influence on kayak performance.

RELATIONSHIP BETWEEN VELOCITIES OF BODY SEGMENTS AND THROWING PERFORMANCES DURING SOCCER THROW-IN MOVEMENT

Yumigeta, R., Asahina, S., Horikawa, H., Tsunoda, N.
Showa University, Japan

In recent years, the use of the throw-in during a soccer game has changed from a simple restart to an offensive weapon, especially in the offensive one-third of the pitch. It has been reported that the sequence of segment rotations from the trunk to the forearm during throw-in movement. However, the relationship between throw-in movement velocities of body segments and throwing performance is not yet clear. The purpose of this study was to clarify the relationship between velocities of body segment and throwing performances during soccer throw-in movement.

The subjects were twenty-seven male university students. Their mean (SD) values of age, height, weight and FFM were 22.0(1.8) yrs, 175.9(6.1) cm, 72.5(8.4) kg and 57.1(4.9) respectively. These subjects performed using two types of throw-in movement were parallel and run-up. Maximal ball distance was determined by a tape measure. The maximal throw-in ball velocity in the distance of 5m was measured by a Radar Gun (Mizuno, Japan). Maximal throw-in movement velocities on body segments for whole body, upper body and upper limb were obtained a custom-made movement velocity measurement system connected to the Speed Meter (VI NE, Japan). The throw-in movement on the sitting position was performed from a custom-made chair, the subjects were tied up with a strap in order to avoid the participation of lower limb during the upper body throw-in movement. And same as lower limb and trunk were tied up in upper limb throw-in movement. Relative value of throw-in movement velocity (PBSV) was calculated as whole throw-in movement velocity compare to each body segment throw-in movement velocity.

Ball distance and velocity in run-up throw-in were significantly higher values than that of parallel throw-in (p<.01). Run-up throw-in movement velocity was significantly higher values than that of parallel throw-in movement velocity (p<.01). PBSV of upper body and limb in run-up throw-in movement were significantly lower values than that of parallel throw-in movement (p<.01). PBSV of lower limb in run-up throw-in movement was significantly higher values than that of parallel throw-in movement (p<.01). Upper body throw-in movement velocity was closely related to ball distance and velocity in two types of throw-in. Upper limb throw-in movement velocity was closely related to ball distance and velocity in two types of throw-in. On the other hand, significantly correlation coefficients were not obtained between PBSV of upper body and ball distance and velocity in two types of throw-in. And also, significantly correlation coefficients were not obtained between PBSV of upper body and ball distance and velocity in two types of throw-in. From these results, it was considered that effect of each body segment throw-in movement velocity to throwing performances has individual character.

AEROBIC EXERCISE TRAINING-INDUCED WEIGHT LOSS IMPROVES ARTERIAL FUNCTION IN OVERWEIGHT AND OBESE MEN

University of Tsukuba, Japan

Background: The prevalence of overweight and obesity has been increasing worldwide. Obesity is an independent risk factor for cardiovascular morbidity and mortality. On the other hand, the reduced arterial function, including central arterial distensibility and endothelial function, implicates in the pathophysiology of cardiovascular disease. It has been well established that regular aerobic exercise is available on weight loss in overweight and obese humans. However, the effect of regular aerobic exercise-induced weight loss on central...
arterial distensibility and endothelial function in overweight and obese subjects has not yet been clarified. Accordingly, the present study was to examine whether weight loss by 12-week aerobic exercise training affects central arterial distensibility and endothelial function in middle-aged overweight and obese men. Methods: Healthy middle-aged overweight and obese men (body mass index >25 kg/m²) completed a 12-week aerobic exercise training program (walking or jogging at 75% of heart rate max for 40-60 min, 3 days/week). Before and after the exercise program, we measured carotid arterial compliance (via simultaneous B-mode ultrasound and arterial tonometry on the common carotid artery) in overweight and obese men. We also determined plasma endothelin-1 (ET-1), a potent vasoconstrictor peptide produced by vascular endothelial cells, and nitric oxide (NO) (measured as the stable end product nitrite/nitrate), a potent vasodilator produced by vascular endothelial cells, concentrations before and after the exercise training in overweight and obese subjects. Results: The aerobic exercise training significantly reduced body weight and resulted in a significant decrease in body mass index. After the weight reduction program, carotid arterial compliance significantly increased. The plasma ET-1 concentration significantly decreased and the plasma NO concentration remarkably increased with aerobic exercise training-induced weight loss. The decreased ET-1 and increased NO suggest the improvement of endothelial function, since ET-1 and NO are implicated in the regulation of vascular tonus. Thus, weight reduction by aerobic exercise training in healthy overweight and obese men not only increased central arterial distensibility, but also improved their endothelial function. Conclusions. Twelve-week aerobic exercise training-induced weight reduction improved arterial function, as evidenced by increased carotid arterial compliance and altered vascular endothelium-derived factors (ET-1 and NO), in middle-aged healthy overweight and obese men. Therefore, our findings suggest that regular aerobic exercise in overweight and obese humans produces beneficial effects on the vasculature, i.e., arterial function, with weight reduction. **BODY COMPOSITION AND PSYCHOLOGICAL FACTORS IN HUNGARIAN GIRLS (3-YEAR FOLLOW UP)**

Völgyi, E., Csende, Z., Mészáros, J.
Semmelweis University, Hungary

It has been revealed that menarche has significant influence on psychological functions in children (Brooks-Gunn and Ruble, 1983). They tend to be embarrassed by the fact that their bodies are more womanly in shape than those of their female classmates that emphasize a lean look.

The aim of this study was to analyze differences in anthropometric variables and psychological factors among Hungarian teenage girls. All together 183 girls were included in the analysis. The mean of their calendar age was 14.98±0.35 at the time of first measurement. The subjects were divided into three groups by tertiles according to the onset of menarche (G1, n=65 early matured; G2, n=62 normal matured; G3, n=56 late matured). Anthropometric measurements were carried out 10 times every 4th month during 3 years observation. Body mass related body fat was estimated by the caliper metric method of Pařízková (1961). Self-administered questionnaires were used to describe state and trait anxiety (Spielberger et al., 1973) and self-efficacy towards physical activity (Schwarzer, 1998). Distribution of the data was checked by Shapiro-Wilk’s W test, and to test homogeneity Levene test of homogeneity has been used. Differences among the groups were analyzed by one-way ANOVA or Kruskal-Wallis ANOVA depending on respective distributions and measurement scales. Significant differences were found in body height, body mass, and body mass related body fat percentage among the groups (p < 0.05). Early matured group was significantly taller until age 13, significantly heavier and they had significantly more body fat in proportion at all measurements. No differences were found in state and trait anxiety and in self-efficacy towards physical activity among the groups at any measurement.

Our conclusion is that the differences among anthropometric characteristics are the consequences of the process of biological maturation, but the pace of their social maturation is not the same. Other factors (family background, type of the settlement where they live) may influence the social behavior. It is important to state that although differences had disappeared in body height after age 13, the significant differences in body mass and body fat percentage still existed. Furthermore, the general statement that early matured children are more anxious is unjustified by our sample. Future investigations should focus in this phenomenon whether this is a sample specific result or the sign of change in the maturation.

**THE EFFECTS OF A WALKING PROGRAMME ON BODY COMPOSITION AND BLOOD PRESSURE OF ELDERLY WOMEN**

Wanderley, F., Carvalho, J.
Faculty of Sport Sciences, University of Porto, Portugal

Numerous studies (Rose et al., 2007; von Huth Smith, 2007) have indicated that physical activity is inversely related to the incidence of cardiovascular disease and mortality. Endurance training, in particular, seems to be able to favourably affect cardiovascular risk factors (CRF) (Fagard, 2006). Walking is considered as one of the most accessible and feasible ways to improve physical activity. So, the aim of the present study was to evaluate the effect of a walking program on elderly’s total and central body fat and resting blood pressure as CRF. Fourteen old women (71.4±5.9 years; BMI= 27.7±2.9 kg/m²; SBP= 142.8±11.1mmHg DBP= 75.1± 4.8mmHg) without habitual exercise practice were evaluated in three distinct moments: baseline (M1), after four months with no exercise (M2) and, finally, after participated in a four month walking program (M3). Three times per week at progressive duration (12-30 min.) and moderate intensity (50-70% of HRreserve) were analyzed 4-5 of Borg scale. Body composition (DXA) and blood pressure were assessed at each moment. Despite the fact that there were no significant alterations after walking program on body composition variables, data demonstrate a significant reduction on women’s sitotic (124.1±12,4mmHg - M3 vs. 136.1±14,0mmHg - M2; p=0.04) and diastolic (65,3 ± 4,8mmHg M3 vs. 70,5 ± 3,9mmHg M2; p=0,015) blood pressure after training (M3-M2). Furthermore, there were significant differences between M3 and M1 both in systolic (124,1± 12.4mmHg - M3 vs. 142.8±11.1mmHg - M1) and diastolic (65,3 ± 4,8mmHg - M3 vs. 75,1 ± 4,8mmHg M1) blood pressure. These findings suggest that a walking program with progressive duration and intensity can be able to improve elderly’s blood pressure and therefore their cardiovascular health.

MOTOR ABILITIES AND ACTIVITY BEHAVIOUR OF NAMIBIAN AND GERMAN CHILDREN

Baer, K., Obermayer, L., Spitenpeifl, P., Schulz, T.
Faculty of Sport Science, Technische Universität München, Germany

Introduction
One of the main topics in Germany is the increasing rate of children with overweight and the risk involved for cardiovascular diseases. Several studies verified the reasons for overweight in a lack of exercise and unhealthy nutrition behaviour. Motor abilities like balance, endurance or speed-strength are decreasing (Bös et al. 2006). The BMI, the fast food consumption and the time children are watching television or playing video games are rising (Kurth, Schaffrath 2007). On the other hand children living in African countries are said to be more active unless there are no available studies about the motor abilities of African children. The aim of the study was to compare the motor abilities and the daily activity behaviour of school children in those different countries, societies and cultures like Namibia and Germany.

Methods
A sample of 191 school children (average 12.81 years, + 1.53) in Namibia (N=93) and Germany (N=98) were tested with a motor ability test battery (jump&reach, long jump, site-to-site, catch&throw, high jump, sit-ups, push-ups, 20m sprint, shuttle run, 1000m run, obstacle course. With every single class the tests were carried out at three days and the classes were split up into girls and boys groups and tested simultaneously. In addition the children filled out questionnaires about their personal data and their activity behaviour (distances to school, membership in a club, leisure time activities). All data were transferred from test result papers to Excel and analysed by SPSS.

Results and discussion
In average the German children had significant better results in the motor abilities: sit-ups, push-ups and site-to-site. The Namibians able was the participation of the subjects running 1000 m (Namibia: 84.95%, Germany: 65.31%). Namibian pupils had more problems solving the obstacle course. A reason might be lack of gymnastic elements in physical education at school. The first questionnaire results indicate that the Namibian children are more active during the day, have lower BMI values (Namibia 16.72, Germany 20.19) and less multimedia consume.

SHIFT-WORKERS PHYSICAL ACTIVITY: A MIXED-METHOD APPROACH

Liverpool John Moores University, United Kingdom

Accurate measurements of shift-workers’ leisure time physical activity (LTPA) are important for reliable estimations of energy balance in this relatively unhealthy cohort (Atkinson et al., 2008). Information is needed not just on mode, duration and intensity of exercise but also when exercise is taken in relation to a specific shift schedule, so that any time-based barriers to exercise are recorded. A mixed-method approach, that combines quantitative and qualitative strategies and cross-sectional and longitudinal designs, is preferable to answer such complicated questions. Using such an approach, our aim is to provide the first detailed account of LTPA in shift-workers.

Shift-workers (46 females and 105 males), with median (inter-quartile range - IQR) age of 39 (14) years, completed the Standard Shift-work Index (SSI) together with a LTPA questionnaire. Gender, job type, age and shift-work experience were explored as correlates of LTPA. Five females and 5 males, with median (IQR) age = 44 (10) y, also completed a 7-day diary and wore an accelerometer for assessment of activity counts during work, leisure, and bed-time when working each shift-type (days, nights and rest). Participants also completed a semi-structured email interview. A transcript-based analysis of interviews was used to identify emerging themes related to LTPA.

The median (IQR) energy expenditure during LTPA was 16.0 (23.4) MJ in males compared to 8.4 (16.3) MJ in females (P=0.002). Firefighters recorded the highest LTPA of 19.1 (23.1) MJ (P<0.0005). Midwives recorded extremely low LTPA, although females are prevalent in this occupation. No significant correlations were found between LTPA and age or shift-work experience (P>0.05). No significant differences in LTPA, work-time and bed-time activity counts were found between shift-type (P>0.05). The number of hours before bed during night shift days was 17.4 (3.5) h compared to 14.6 (2.5) h on rest days (P=0.004). Participants stated that sleep-related disturbances affected their desire to take part in LTPA and increased their need to recover on rest days. The amount of time participants could spend socialising with friends, family, domestic activities and LTPA was also stated to be limited by shift-work.

In conclusion, male shift-workers within the fire and rescue services participate in the most LTPA, with female midwives having the lowest levels of LTPA. Job-type and gender were much more influential on the LTPA of shift-workers than age or experience. Shift-workers spend more of their time on rest days in bed, in an attempt to rectify a perceived sleep debt, which is emphasised more than LTPA. Such information from these mixed-methods will be useful in informing the design of future physical activity interventions administered to individual shift-workers.

PHYSICAL ACTIVITY, FITNESS AND OVERWEIGHT IN CHILDREN AND ADOLESCENTS: THE MADEIRA GROWTH STUDY

Regional Department of Education and Culture, Portugal

The purpose of this study was to compare the physical activity and fitness levels of overweight and non-overweight Madeira children and adolescents. The sample included 507 subjects which participated in the Madeira Growth Study, a mixed longitudinal study with five cohorts followed at annual intervals during three consecutive years. A total of 1505 subjects, 761 boys and 744 girls, 7-18 years old, was used in a cross-sectional analysis of the data. Somatic characteristics include stature and body weight. Physical activity was estimated via questionnaire and interview. Physical fitness was measured with the Eurofit test battery. Body mass index was used as overweight indicator. The sam-
EFFECT OF COMBINING LACTOTRIPEPTIDE SUPPLEMENT WITH REGULAR EXERCISE ON CENTRAL ARTERIAL COMPLIANCE AND VASCULAR ENDOTHelial FUNCTION

Yoshizawa, M., Maeda, S., Miyaki, A., Misono, M., Saito, Y., Shimojo, N., Aijisaka, R., Tanaka, H.

University of Tsukuba, Japan

BACKGROUND: Central arterial compliance and vascular endothelial function play an important role in the functional abilities of the vasculature, whereas these functional abilities of the vasculature decline with aging. Indeed, the reduced arterial compliance and endothelial function implicate in the pathophysiology of cardiovascular disease. Two tripeptides, valine-proline-proline (Val-Pro-Pro) and salseucine-Pro-Pro-Pro-Pro-Pro), were isolated from the sour milk and were referred to lactotripeptide (LTP). LTP had an antihypertensive effect. Regular exercise can improve functional abilities of the vasculature, i.e., central arterial compliance and vascular endothelial function. We hypothesized that combining these lifestyle modifications (i.e., LTP supplement with regular exercise) might be more effective than either treatment alone. OBJECTIVE: We examined the individual and combined effect of LTP supplement and regular exercise on central arterial compliance and endothelial function. METHODS: Twenty-nine postmenopausal women (51-60 years old) volunteered to participate. The subjects were randomly assigned to one of the following interventions: LTP, placebo (control), LTP and exercise (LTP+Ex), or placebo and exercise (Placebo+Ex). LTP (6.8 mg/day) or placebo was administered orally for 8 weeks. The exercise group performed regular aerobic exercise (primarily walking) 4 day/week for 45 min at 75% peak heart rate. Before and after an 8-week intervention program, we measured blood pressure, carotid arterial compliance (via simultaneous B-mode ultrasound and arterial applanation tonometry on the common carotid artery), and endothelial function (assessed with flow-mediated dilatation [FMD]). RESULTS: After 8 weeks intervention, systolic blood pressure, carotid arterial compliance (via simultaneous B-mode ultrasound and arterial applanation tonometry on the common carotid artery), and endothelial function (assessed with flow-mediated dilatation [FMD]) significantly increased after an 8-week intervention of LTP, Placebo+Ex and LTP+Ex. There were no significant differences in carotid arterial compliance and FMD before and after placebo intervention. Carotid arterial compliance and FMD significantly increased after an 8-week intervention of LTP, Placebo+Ex and LTP+Ex. There were no significant differences in carotid arterial compliance and FMD before and after placebo intervention. The change of carotid arterial compliance was markedly higher in LTP+Ex group than other groups and the change of FMD was significantly higher in LTP+Ex group than Placebo and LTP groups. CONCLUSIONS: LTP supplement or regular exercise improves the functional abilities of the vasculature, i.e., central arterial compliance and endothelial function. The combining LTP supplement and regular exercise are more effective than either treatment alone.

SIGNIFICANT MODIFICATIONS IN BODY COMPOSITION AND CARDIO-RESPIRATORY FITNESS INDUCED BY A SPECIFIC INDOOR CYCLING PROTOCOL

Bianco, A., Bellaﬁore, M., Pilano, A., Battaglia, G., Palma, A.

University of Palermo, Italy

Indoor cycling (IC) has been suggested as a physical activity for losing weight; however these studies have never been published in peer-reviewed scientific journals. Moreover, despite its worldwide popularity incomplete studies aimed at assessing the IC effects on metabolic and cardiovascular functions are present. The aim of our study was to evaluate whether IC is suitable for decreasing fat mass and improving cardio-respiratory fitness (CRF) in ten sedentary overweight women. The subjects (22.6±2.1 yr, 25-29.9 BMI) were trained for 12 weeks by a speciﬁc indoor cycling protocol (ICP) that follows the guidelines of Schwin® Cycling program. The training consisted of 3 sessions/week (each session length: 53min and 03sec) carried out from 7 to 8 pm in ﬁtness room at the University Campus of Palermo. Body circumferences (arm, chest, abdominal, thigh and leg) were measured according to Lohman et al. Body composition was evaluated by bio-impedance analysis. Heart rate (HR) and oxygen uptake (VO2) were monitored by a HR monitor and a wireless portable ergospirometer system respectively. Triangular incremental test created by Mac Dougall et al. was modiﬁed and used for evaluating cardio-respiratory performance after ICP sessions. The data were acquired before the beginning of the protocol and after 12, 24, 36 ICP sessions. Repeated analysis of variance (ANOVA) and linear regression test among the continuous variables and single values were performed. Statistical signiﬁcance was set at P < 0.05. The initial body weight (70.8±8.8 kg) showed a reduction by 2.6% and 3.2% after 24 and 36 Indoor Cycling Sessions (ICS) respectively. Moreover, we observed a signiﬁcant reduction by 4.3% and 5.0% in fat mass after 24 and 36 ICS respectively. Lean mass signiﬁcantly increased by 2.3% and 2.6% respectively after 24 and 36 ICS. All circumference measures signiﬁcantly diminished in response to ICS. Resting heart rate (70.2±10.1 beats•min−1) decreased by 6.5% and 9.0% after 24 and 36 ICS respectively. Training Heart Rate (HRt) and Training Oxygen Uptake (VO2t) gradually increased during warm up step and reached the peak in the middle part of training period. Instead, they gradually decreased during cool down step. The results of incremental test showed a signiﬁcant increase in HRmax, Wattpeak and VO2max after ICP sessions. The signiﬁcant decrease in the body weight suggests the efﬁciency of our protocol for losing weight in overweight women. ICP intensity might induce a high energy expenditure as suggested by HR and VO2 values recorded during ICP sessions. The proﬁles of HRt and VO2t were strongly dependent on the selected technique, hand position and music tracks and therefore the instructor may modulate the workload according to the individual features. The presence of cardiac adaptations associated with the results from incremental test suggests that our protocol may improve CRF and be used to prevent cardiovascular diseases.
MAXIMAL OXYGEN UPTAKE IN A NATIONALLY REPRESENTATIVE SAMPLE OF NORWEGIAN 9- AND 15-YEAR OLDS

Kolle, E., Steene-Johannessen, J., Andersen, L., Anderssen, S.
Norwegian School of Sport Sciences, Norway

In children low aerobic fitness has been associated with cardiovascular disease risk factors (1). Moreover, aerobic fitness seems to track from childhood into adulthood (2). Even though direct measurement of VO2peak is the preferred method to assess aerobic fitness, it is rarely used in large epidemiologic studies due to expensive equipment and its time consuming nature. Population based studies where VO2peak has been measured directly are scarce. Aim: The aim was to assess aerobic fitness in a population based sample of Norwegian 9- and 15-year olds. Methods: The study was carried out in 2005-2006. A total of 2,299 9- and 15-year-olds participated, giving an adherence rate of 82%. Oxygen uptake was measured directly using a maximal cycle ergometer test. Expired gas was measured with a portable MetaMax III X oxygen analyser. Differences between groups were analysed using independent-sample t-test. P-values ≤ 0.05 were considered statistically significant. Results: Mean values for VO2peak were the following: 9-year old boys, 48.2±7.1 ml/min/kg; 9-year old girls, 42.9±6.7 ml/min/kg (12.4% sex difference, p<0.0001); 15-year old girls, 41.1±6.0 ml/min/kg, 15-year old boys 51.9±8.0 ml/min/kg (26.3% sex difference, p<0.0001). Furthermore, 15-year old boys had 7.7% higher VO2peak than 9-year old boys (p<0.0001), whereas 9-year old girls had 4.4% higher VO2peak than 15-year old girls (p<0.001). Conclusions: This study indicates that sex differences in aerobic fitness are present in prepubertal children as well as in adolescents. The least fit subjects had VO2peak of 30-36 ml/min/kg. These values are below the considered criterion standard for health related aerobic fitness. Low aerobic fitness is of concern, due to the strong association that has been reported between low aerobic fitness and clustering of risk factors for cardiovascular disease. Since aerobic fitness seems to track into adulthood, interventions should be targeted especially at these groups.

EFFECTS OF A LIFESTYLE-BASED PHYSICAL ACTIVITY PROGRAM ON METABOLIC SYNDROME IN JAPANESE MALE OFFICE WORKERS

Tanabe, K., Yokoyama, N., Maeda, S., Iemitsu, M., Sakato, Y., Nanba, H., Zenpo, H., Kuno, S.
University of Tsukuba, Japan

PURPOSE: Among Japanese middle-aged workers, enhanced individual with metabolic syndrome is a significant problem because of the possibilities of more cardiovascular disease occurrence and more health care expenditure. There is a need for effective preventative health promotion program against metabolic syndrome, designed to be accessible to more people and support to long-term adherence. This study investigates the effects of a lifestyle-based physical activity intervention program on metabolic abnormalities in Japanese middle-aged male office workers. METHODS: Data collected on healthy sixty-nine males (aged 45.7±7.8 years) participating in a lifestyle-based physical activity intervention program delivered to employees from a single corporation were analyzed at baseline and after 3 months. Components of the intervention include supervised low-to-moderate intensity physical activity including combined aerobic activity, 8,000-10,000 steps/day and resistance-training (seven weight-bearing resistance exercises, for an estimated 30 min completed 5 days/week), and dietary education (delivered via group seminars). These training were performed at the time and location that would suit their lifestyle. Metabolic syndrome-related factors (waist circumference, blood pressure, blood glucose level, and lipid profile) and physical fitness, as well as energy intake and expenditure were measured. The metabolic syndrome was assessed using the Japanese definition, launched in 2005. RESULTS: After 3 months, the prevalence of metabolic syndrome was markedly lower (19%, 13 subjects) than at baseline (45%, 31 subjects). Body weight, waist circumference, blood pressure, fasting blood glucose level, and triglyceride level, and LDL cholesterol level were significantly decreased after 3 months (p<0.05). The increase in energy expenditure and physical fitness had a significant correlation with changes in metabolic syndrome-related factors. CONCLUSION: These results suggest that a lifestyle-based physical activity intervention can improve and prevent metabolic syndrome over a short-term period in middle-aged office workers.

VALIDITY OF HEART RATE AND ACCELEROMETRY TO ASSESS PHYSICAL ACTIVITY ENERGY EXPENDITURE WITH AND WITHOUT INDIVIDUAL CALIBRATION IN FREE-LIVING ADOLESCENTS

Corder, K., Brage, S., Wright, A., Wareham, N., Ekelund, U.
Institute of Metabolic Science, United Kingdom

Introduction
The strength of the relationships between physical activity energy expenditure (PAEE) and disease remain uncertain. This is at least partly because PAEE is difficult to measure accurately in young people. Combining heart rate monitoring (HR) and movement sensing (ACC) has improved the accuracy of PAEE prediction over either method used alone in laboratory settings in youth, but not yet during free-living. Both HR and ACC have limitations, including the need for individual calibration of HR. The aim of this study was to determine the validity of HR+ACC to assess free-living PAEE in adolescents, with and without individual calibration of HR.

Methods
Fifty-four adolescents (12 to 18 years-old) were recruited from schools in Cambridgeshire, UK. Energy expenditure (EE) was measured during rest and incremental treadmill activity by indirect calorimetry. Subsequently, combined HR and ACC monitoring was carried out over 11 consecutive days concurrent with EE measurement using the doubly labelled water method (DLW). Five combined and separate HR+ACC prediction models were derived, and PAEE subsequently predicted, using either group (GC) or individual (IC) HR calibration:

- a. Cubic ACC model
- b. Flex HR model with GC of HR
- c. Flex HR model with IC of HR
- d. HR+ACC with GC of HR
- e. HR+ACC with IC of HR

Acceleration and/or beats per min above sleeping HR (HRaS) and sex were included in GC models. The individual slope and intercept of the HR-EE relationship derived during the treadmill calibration was included in the IC models. The models were derived using repeated
**Results**

Mean bias was highest for the ACC model (-46.8 kJ/kg/day; p<0.001) and lower for the Flex HR (10.8 and 9.6 kJ/kg/day, p=0.007 and 0.071) and HR+ACC models (-7.7 and -10.5 kJ/kg/day, p=0.04 and 0.01). The root mean square error was also highest for the ACC model (55.9 kJ/kg/day) compared to the HR (30.1 and 39.1 kJ/kg/day) and HR+ACC models (27.4 and 30.6 kJ/kg/day). Systematic error was present for models a, c, and d, with correlations ranging from r=-0.28 to r=0.44 (p=0.04 to p<0.001) between the difference and the mean of estimated PAEE. There was no difference in mean bias between the estimates from the group- or individually-calibrated Flex HR or HR+ACC models (p=0.75 and p=0.31, respectively).

**Conclusion**

The Flex HR and HR+ACC models provided more accurate predictions of PAEE than the model based on ACC alone. There appears to be little benefit in using HR+ACC over HR alone for the prediction of PAEE in these adolescents. Our results also suggest that individual calibration of HR does not appear necessary for the prediction of PAEE over the use of sleeping heart rate and sex for the group calibration of HR.

**HOW DOES EXERCISE FREQUENCY BEFORE AND DURING PREGNANCY AFFECT THE RISK OF DELIVERING HIGH BIRTH WEIGHT INFANTS. THE NORWEGAN MOTHER & CHILD HOJT STUDY**

Owe, K., Nystad, W., Bø, K.

Norwegian School of Sport Sciences, Norway

**Introduction**

Mean birth weight has increased during the last decades (1) with an increased proportion of infants weighing above 4000 g, which is associated with an increased risk of adverse pregnancy and maternal outcomes. Although recreational exercise (RE) during pregnancy has been considered an important determinant of birth weight, the literature on the relationship between RE during pregnancy and birth weight is equivocal. Whether the differences in birth weight are dependent upon the physical conditioning of the mother previous to pregnancy, exercise frequency or timing of exercise during pregnancy remains unknown. Hence, the aim of the present study was to investigate, in the same cohort of pregnant women, the association between exercise frequency before and during pregnancy-week 17 and 30, and the risk of giving birth to high birth weight (>4000 g) infants. Methods: Using data from the Norwegian Mother and Child Cohort study (MoBa), 36869 pregnancies enrolled between 2001 and 2005 were included. Multiple pregnancies and pregnancies ending before week 37 were excluded. Information on recreational exercise was based on answers from two questionnaires distributed in pregnancy-week 17 and 30. Linkage to the Norwegian Medical Birth Registry (MBR) provided data on birth weight. Recreational exercise level was defined in terms of frequency. Outcome variable was delivery of a high birth weight infant (>4000g). We used logistic regression analysis to estimate the associations, and the results are presented as adjusted odds ratios (aOR) with 95% confidence interval (95% CI). The following covariates were included; maternal age, BMI prepregnancy, maternal height, prepregnancy exercise frequency, smoking, hypertension, Preecampsia, Preexising Diabetes, and Preexisting/GDM. Results: The proportion of infants with birth weights above 4000 g was 24.4% (n=8991). Exercising 3 1 pr week or more in week 17 was negatively associated with giving birth to high birth weight infants in nulliparous women, aOR=0.81 (95% CI 0.71-0.93). In week 30, both nulliparous and multiparous women exercising 1-2 t a week were less likely to deliver high birth weight infants, aOR=0.87 (0.77-0.97) and 0.91 (0.84-0.995), respectively, with the greatest protective effect in nulliparous exercising 3 1 pr week or more, aOR=0.78 (0.69-0.88). Prepregnancy exercise frequency did neither affect the probability of delivering high birth weight infants in nulliparous nor in multiparous women. Conclusion: A protective effect of exercise frequency in week 17 was observed in nulliparous women, only. Exercise frequency in late pregnancy may have a greater impact on excessive birth weight compared to prepregnancy and week 17, both in nulliparous and multiparous women. The probability of delivering high birth weight infants was not affected by exercise frequency prepregnancy.

**VARIABILITY IN LIMB MUSCLE SIZE IN 633 JAPANESE MEN AGED 18-39 YR**

Waseda University, Japan

**Introduction**

Muscle size is related to the force production capability, and changes with training, growth and aging. Kawakami et al. (2) have measured muscle thicknesses in 711 women and men aged 3-94 years and found that the inter-individual variability in muscle sizes was different among the triceps brachii, vastus lateralis and medial gastrocnemius muscles. They indicated that the muscle-dependent variability in size reflected inter-muscle differences in hypertrophic response to training and/or growth. However, their measurement is varied muscle thicknesses in 711 women and men aged 3-94 years and found that the inter-individual variability in muscle sizes is dependent on muscle groups. The elbow extensors were highly variable in size, and the lower leg muscles had lower variability. Since the present data were obtained from the men aged 18-39 yr, the observed differences in the variability cannot be ascribed to either of gender, growth or aging. The subjects included college athletes of various sports. The muscle thicknesses were determined by ultrasonography at each of 12 sites: upper arm anterior (12.2%), upper arm posterior (12.1%), lower leg anterior (9.4%) and lower leg posterior (9.4%). The differences in CVs between measurement sites were significant in all cases except for those of upper arm anterior-thigh posterior and lower leg anterior-posterior. The results were the same even when each of the muscle thickness was normalized to the limb length to account for the variation in body size.

**Discussion**

Our main finding is that the inter-individual variability in muscle thicknesses was dependent on muscle groups. The elbow extensors were highly variable in size, and the lower leg muscles had lower variability. Since the present data were obtained from the men aged 18-39 yr, the observed differences in the variability cannot be ascribed to either of gender, growth or aging. The subjects included college athletes of various sports.
athletes (e.g., baseball, volleyball and sumo wrestling) with various training history and routines. Thus, the results suggest muscle-related differences in hypertrophic response to training. These differences may be related to the muscle architecture (fiber length/muscle length (2) and pennation angle), duration and level of activation during daily living (3) and function (extensor or flexor). The differences in hypertrophic responses between muscle groups should be taken into account when one evaluates the effects of resistance training.

EFFECTS OF BODY COMPOSITION ON SWAY
Moreno López, R., Rubio Arias, J., Jiménez Díaz, J.
Faculty of Sport Science of Toledo, Spain

INTRODUCTION
Alterations in the type of foot can be produced by physical activity (Nagel, Fernholz et al. 2008), and have as a result in a predisposition to suffer injuries (López, Albuerqueque et al. 2005). The study of plantar pressures is taking a great importance and Platforms Pressures (PP) are being used to obtain stabiometric and podometric measures (Dowling, Steele et al. 2004). PP gets faster, cleaner and more accurate data, as type of foot (although there are studies which criticize it) (Urry and Wearing 2001) or displacement of Gravity Center (IGCsway). Furthermore, sway can be conditioned by body composition (Bernard, Geraci et al. 2003).

OBJECTIVES
To study the influence of body composition in displacement of GC in physical healthy subjects.

MATERIAL AND METHODS
Subjects: 42 subjects (mean age = 22.42±5.14 years; height = 180±9.03 cm; weight = 80.74±13.72 kg).

Instruments: It was used a PP with a surface area of 60x58 cm (Footwork-Pro), with a sampling frequency of 300 Hz. Anthropometric measurements were used a Seca system, with a sensitivity of 1mm, and body composition was analyzed by bioelectrical impedance (Inbody720).

Protocol: data were carried out on three consecutive days. First, height, weight and body composition were analyzed. Then, a test with the PP consisting of a static bipodal, fundamental position.

Statistical Analysis: It was carried out using SPSS 15.0 program and averages and standard deviations were taken. The correlations were found with Pearson’s test for variable parametric and Spearman for nonparametric. The distribution of variables were analyzed with Sahpiro-Wiklks test. Finally, Student’s test was used, considering p value <0.05 as significant and U Mannwhitney.

RESULTS
In the population study were found correlations between displacement of Gravity Center with the skeletal-muscle mass (r left foot = - 0.721); (r body = -0.939) and (r right foot = -0.636).

CONCLUSIONS
The increased in body fat means a decrease in the ability to balance (Goulding, Jones et al. 2003; Paillard, T. Lafont C et al. 2004), and the type of foot is not linked to body composition.

PHYSICAL ACTIVITY, SPORTS PARTICIPATION, AND PHYSICAL FITNESS OF CHILDREN WITH VISUAL IMPAIRMENTS
Houwen, S., Hartman, E., Visscher, C.
University Medical Center Groningen, University of Groningen, Netherlands

Low physical fitness levels have been found in children with visual impairments (VI), and it has been suggested that this is partly related to low physical activity levels (Lieberman & McHugh, 2001; Kozub & Oh, 2004). Reported data which might indicate whether there is a relationship between physical activity and physical fitness in children with VI are scarce. Therefore, the aim of this study was to investigate the physical activity level of children with VI and its association with physical fitness performance.

A sample of 48 children with VI, ages 6 to 12 years, participated. Physical activity was assessed by the GT1M accelerometer, sports participation by a self-report measure (see Houwen et al., 2007), and physical fitness by the Eurofit (see Houwen et al., 2006). BMI was also determined. Partial correlation analyses corrected for age, sex, BMI, and degree of VI were used for statistics. The following accelerometer outcome variables were calculated: (1) total physical activity (counts per minute), (2) number of minutes spent in sedentary activity per day, (3) number of minutes spent in light activity per day, and (4) number of minutes spent in moderate-to-vigorous activity (MVPA) per day.

The results of the self-report measure indicated that a large percentage (80%) of the children with VI participated weekly in sports activities. Children with VI participated primarily in individual sports with a closed (= stable, predictable) character. Despite their reported sports participation, none of the children with VI met the recommendation of being physically active for at least 60 min/day on every day of the week according to the accelerometer data (Kemper et al., 2000). With regard to associations between physical activity and fitness, it was found that total physical activity was significantly associated with sit-and-reach, standing broad jump, sit-ups, and modified 5x10-m shuttle run, indicating that children who were more active reached farther, jumped farther, performed more sit-ups, and were faster on the shuttle run than children who were less active. Percentage of time spent in sedentary activity was inversely associated with sit-and-reach, standing broad jump, sit-ups, and positively with the 5x10-m shuttle run. Percentage of time spent in MVPA was positively associated with sit-and-reach and sit-ups.

Physical activity needs to be promoted in children with VI. Focusing on reducing time spent in sedentary activities and enhancing participation in MVPA may be successful means of promoting physical fitness in children with VI.

PATTERNS OF PHYSICAL ACTIVITY IN 9 AND 15 YEARS-OLD CHILDREN IN ICELAND

Arnadóttir, N., Arngrímsson, S., Johannsson, E., Sveinsson, T.
University of Iceland, Iceland

Lack of physical activity is hypothesized to be an important factor in the development of childhood obesity. This places children and adolescents at increased risk of significant health problems, both during their childhood and adult life. At the same time, physical activity has been shown to decrease by age and be less among girls than boys. The purpose of this study was to compare physical activity patterns of weekdays and weekend days and examine whether these patterns are influenced by age and gender. In this study, 435 randomly selected 9 (9YO) and 15 (15YO) year-old children from 18 primary and/or secondary schools in Iceland participated. Physical activity was measured with Actigraph activity monitors over 3-5 days. Total counts per day were used as objective measure of physical activity. Statistical analysis was done with factorial ANOVA for repeated measures in SPSS, using Greenhouse-Geisser correction for sphericity. Using weighted average of weekday and weekend physical activity, 9YO (girls= 528±166 kcounts/day, ±SD), boys= 620±186 kcounts/day) were significantly more active than 15YO (girls= 425±130 kcounts/day, boys= 543±195 kcounts/day, F= 37.2, df= 1,334, p<0.001), and boys were significantly more active than girls (F= 33.0, df= 1,334, p<0.001). Physical activity was lower during weekend days (F= 253.3; df= 1,334, p<0.001), and the difference was independent of age and gender. The physical activity pattern was not the same on weekdays and weekend days (F= 27.4, df= 10.6,3535; F= 0.001), but this difference was both moderated by age (F= 12.6, df= 10.6,3535; p<0.001) and gender (F= 2.30; df= 10.6,3535, p=0.009). The 9YO were most active in the morning and around noon during weekdays but on weekend days they were most active from noon to 6:00 pm. The 15YO were most active in the afternoon on both weekdays and weekend days. However, on weekend days they were much more active in the evening and during the night than during weekdays. Whereas the activity pattern is similar for boys and girls on weekend days, on weekdays it differs. For boys it peaks around noon but in the late afternoon for girls. In conclusion, the difference in physical activity patterns both between different age groups and between gender should be considered when intervention strategies to increase physical activity are planned and implemented.

THE WHOLE-BODY VIBRATION IS USEFUL TO IMPROVE THE DYNAMIC BALANCE IN WOMEN WITH THE SYNDROME OF FIBROMYALGIA

Parraca, J., Gusi, N., Olivares, P., Adsuar, J.
University of Extremadura, Spain

Introduction:
Recently it has been demonstrated that there is a usual deficit in balance in people with fibromyalgia. In some studies it has been seen that balance can be improved with different programs of vibratory exercise in different risk population as older people.
Objective:
The purpose of this study is to assess if a whole-body vibration exercise program from 12 weeks to 12.6 hertz of frequency. It will begin with repetitions from 30 seconds to 1 minute. The aim is to check if those are useful, safe and applicable in women with FM syndrome for the improvement of the dynamic balance.
Material and Method:
36 women with fibromyalgia syndrome have participated in this study. They were randomly assigned in two groups. 18 in the control group and 18 in the exercise group. The isometric force has been moderate using the isocinetic dynamometer system 3, the dynamic balance through the platform of balances Biodex Balance. The training program lasted 12 weeks, three weekly sessions were offered. Each session consisted of 6 repetitions to 12.5 Hertz with an initial duration of 30 seconds that was increased monthly, in 15 seconds. Between each repetition a rest of a minute existed.
Results:
The exercise group in relation to the control group, has improved in a significant way his dynamic balance improving the more those who had a smaller level of isometric force and those that had a greater weight because of the relative load of training was greater.

ASSOCIATION BETWEEN SPORT PARTICIPATION AND THE DEGREE OF SEVERITY OF OBESITY IN CHILDREN AND ADOLESCENTS

Almeida, S., Almeida, M., Gouveia, E., Leça, L., Rodrigues, A.
University of Madeira, Portugal

Introduction: Nowadays, due to the dramatical change in people’s lifestyles and the physical environment, children have few opportunities for active playing and spontaneous physical activity. Therefore, participation in organized physical activity such as physical education (PE) and sport teams are probably the major source for total activity. The increasing prevalence of childhood obesity in the last decades has been a growing concern, and it has been associated with low levels of physical activity. The aim of the present study was to determine the association between sport participation and the degree of severity of obesity.
Methods: The sample comprised 465 children and adolescents, from public schools and sport clubs in Funchal. (Autonomous Region of Madeira) with a mean age of 13.72±1.64 years. According to their level of sport participation, subjects were classified in two groups: 1) only attending PE classes (Gp1), and 2) attending PE classes as well as playing sport in school and/or club sport teams (Gp2). Based on their body mass index (BMI), subjects were classified according to Cole et al. (2000) percentiles. Similarly, for percent body fat, subjects were classified according to the Lohman’s (1987) health risk categories. Sport participation was assessed by self-report questionnaire.
Results: Subjects who only took PE classes (Gp1) presented a higher risk of being overweight (OR 0.7, 95% CI 0.4-1.2) and obese (OR 1.2, 95% CI 0.4-3.1) than that of Gp2. Similar results were found with subjects in Gp1, showing a greater risk of being in the moderately high
EVIDENCE OF THE RELATIONSHIP BETWEEN CARDIOVASCULAR DISEASE, OBESITY, AND METABOLIC SYNDROME

INTRODUCTION

The purpose of this study is to determine the relative importance that several international certifications, recognized as the most prestigious (1), grant to different knowledge fields. It seems that, to be certified is very related with outstanding knowledge for the P.T. professional practice (2). The certifications studied are under NCCA accreditation, required by IHRSA since 2005 in order to recognize any PT certification (3).

MATERIAL AND METHODS

Contents of 5 international PT certifications programs were analyzed: NSCA, ACSM, NASM, ACE and The Cooper Institute. Distribution of the contents in 8 categories that include all KSAs that should have a PT, according to these organizations. A national panel of experts validated the election and definition of the categories, afterwards we distributed the contents of each certification in these categories. When any content didn't agree exactly with those owned to this study, an interpretation was carried out, assigning the relative importance based on researchers criteria.

Statistical analysis used measures of central tendency (mean and standard deviations), as well as coefficient of variability (C.V.).

RESULTS

The categories resulted from the analysis are: exercise programming and prescription (EPP), exercises technique (ET), applied sciences (AS), physical fitness testing and interpretation (PFT), nutrition (N), marketing and business issues (MB), safety and emergency management (SEM), legal issues (LI). The most relevant category is EPP, with an average of importance among all certifications of 34.6%. It's followed by ET, AS and PFT, all of them with an importance higher than 19%. Resting categories (N, MB, SEM and LI) have an importance average lower than 10%. The relevance of the M category is the most heterogeneous, data that indicates a great disagreement among the studied certifications in relation to this aspect of PT competence.

CONCLUSIONS

EPP is the most important content, followed by ET, AS and PFT. On the other hand, N, MB, SEM and LI are the categories considered as less relevant.

PRACTICAL APPLICATIONS

PT educational programs should distribute their contents and schedules in a similar way to the results obtained in this study. References.

METABOLIC SYNDROME AND OBESITY IN CHILDREN AND ADOLESCENTS (3-15 YEARS) FROM MADEIRA (PORTUGAL)

Cardiovascular diseases (CVD) are the first cause of morbidity and mortality at world level. CVD appears mostly associated to a group of factors such as hypertension, dyslipidemia, elevated plasma glucose and obesity, whose constellation has been named the metabolic syndrome (MetS). The purposes of this study were: a) to determine the prevalence of MetS in a sample of Portuguese children and adolescents living in Madeira Island, and b) which components are the best predictor(s) of MetS in this sample.

Methods:

Participants in this study were 1496 children and adolescents ranging from 3 to 15 years of age from the public school system in the island of Madeira. Measures taken for each subject were: body composition (weight, height and waist circumference), blood pressure, triglycerides, glucose and C-HDL. MetS was diagnosed using the criteria established by Cook et al. (2003). Prevalence of obesity and overweight was determined according to the Cole et al. (2000) classification.

Results:

Results show that 17.6% of participants were overweight and 6.5% were obese. The prevalence of MetS was 4.5% (3.4% in girls and 5.7% in boys), and it raised with the increasing severity of obesity (11.1% in normal weight, 11.8% in overweight and 22.9% in obese subjects), as well as the increasing school level (4.0% in preschool, 4.8% in 5-6th grades, and 5.5% in 7-9th grades). Logistic regression analysis showed that abdominal obesity was the MetS component that presented more risk for the diagnose of that condition (OR: 1.185; ICC 95% 1,062-1,251), followed by systolic blood pressure (OR:1.063; ICC 95% 1,016-1,112) and triglycerides concentration (OR:1.048; ICC 95% 1,035-1,062).

Conclusions:

The prevalence of the MetS was higher in boys than in girls and it increases with the severity of the obesity and school level. The best predictor of MetS was the waist circumference.

HEALTH CLUB CLIENTS: A STUDY OF THE SEGMENTATION CRITERIA

Teixeira, M., Correia, A.

Universidade de Évora / Faculdade de Motricidade Humana, Portugal

Health Club Clients: a study of the segmentation criteria

Teixeira, Mário & Correia, A.

This study segments the clients of fitness centre on the Portuguese island of Madeira, based on cluster analysis. A questionnaire with 121 observations is used to examine the motivation profiles. The findings reveal that there are three segments in the data: the first is denominated the 'happy consumer' segment. The second segment consists of the 'unhappy consumers' and the third are composed of unmarrried, unattached consumers. The managerial implications of the results are derived.

Biographical notes:

Mário Coelho Teixeira currently teaches Sport Management in the Department of Sport and Health at the University of Évora, Portugal. He is a PhD student and has a Master's degree in Sports Management from the Technical University of Lisbon.

Abel Correia has a PhD in Human Kinetics, specialising in Sport Sciences at the Human Kinetics Faculty of the Technical University of Lisbon (FMH-UTL). As an associate professor working in the Sport Sciences Department, he teaches Sports Organisation and Sports Marketing on the FMH-UTL's degree course in Sports Management. His interests include sports organisational strategy and sports marketing management.

INFLAMMATORY PROTEINS ARE ASSOCIATED WITH MUSCLE STRENGTH IN ADOLESCENTS; THE AVENA STUDY

Ruiz, J., Ortega, F., Warnberg, J., Moreno, L., Carrera, J., Gonzalez-Gross, M., Marcos, A., Gutierrez, A., Sjöström, M.

(1) University of Granada, Spain, (2) Karolinska Institutet, Sweden, (3) Consejo Superior de Investigaciones Científicas, Spain, (4) University of Zaragoza, (5) Universidad Politecnica de Madrid, Spain

Objective: to examine the associations between inflammatory proteins and muscle strength, and to determine whether this association varies between overweight and non-overweight adolescents.

Main exposures: A total of 416 Spanish adolescents (230 males, and 186 females) aged 13-18.5 yrs participated in this study. Muscle strength score was computed as the mean of the handgrip and standing broad jump standardized values. The adolescents were categorized as overweight and non-overweight according to body mass index. Body fat and fat free mass were derived from skinfold thickness. Inflammatory markers measured: C-reactive protein, complement factors C3 and C4, ceruloplasmin and transthyretin.

Results: The results of the regression analysis showed that C-reactive protein, C3 and ceruloplasmin were negatively associated with muscle strength after controlling for sex, age, pubertal status, weight, height, socioeconomic status, and cardiorespiratory fitness. Moreover, C-reactive protein and transthyretin were associated with muscle strength in overweight adolescents after controlling for potential confounders, including body fat and fat free mass.

Conclusions: Low-grade inflammation is negatively associated with muscle strength in adolescents. The patterns of these associations seem more relevant in overweight adolescents, suggesting that having high levels of muscle strength may counteract the negative consequences ascribed to body fat.

INFLUENCE OF PHYSICAL ACTIVITY ON RADIUS AND TIBIA QUANTITATIVE ULTRASOUND MEASUREMENTS IN PERIPUBERTAL GIRLS

Soutello, L., Baptista, F., Fragoso, I., Vieira, F., Barrigas, C., Sardinha, L.

Faculty of Human Movement, Portugal

The purpose of this study was to investigate the influence of physical activity on radius and tibia quantitative ultrasound measurements in peri-pubertal girls. Participants were 174 peri-pubertal girls ages 9.2 to 13.1 yrs, divided into three groups according Tanner stage of puberty, namely, group II (age:10.8+/-0.9 yrs; bone age:10.5+/-1.1 yrs; height:145.5+/-9.5 cm; BMI:16.4+/-3.1 Kg/m²; fat mass:18.4+/-6.5 %), group III (age:11.3+/-0.9 yrs; bone age:11.3+/-1.1 yrs; height:149.5+/-7.6 cm; BMI:18.3+/-3.1 Kg/m²; fat mass:20.5+/-6.3 %), and group IV (age:12.5+/-0.5 yrs; bone age:13.6+/-1.2 yrs; height:149.0+/-6.0 cm; BMI:19.0+/-2.0 Kg/m²; fat mass:20.1+/-5.0 %).

Evaluation of radius and tibia was conducted with quantitative ultrasound [Sunlight Omnisense] and physical activity [PAI] with the Actigraph accelerometer (GT1M) over seven days. The outcome PA variables were the number of minutes the child engaged in activity of different intensities. Cut points of 100 and 1952 counts/min represent sedentary, light, and moderate plus vigorous PA. Pubertal maturation was assessed according secondary sex characteristics (Tanner, 1962). Body composition was estimated through Slaughter et al. (1988) and Lohman (1986) equations. The % body fat was obtained using the mean value of the two equations. Bone age was determined by the Tanner-Whitehouse III Method. Energy and calcium intake were calculated from a semi-quantitative Food Frequency Questionnaire assessing regular intake of a wide set of typical Portuguese foods. Results: ANOVA demonstrated that girls on the group IV have higher radius and tibia speed of sound than girls on the group III and II (radius: IV:3827+/-101 vs. III:3779+/-87 vs. II:3763+/-91 m/s, p=0.004, tibia: IV:3720+/-122 vs III:3677+/-97 vs II:3648+/-108 m/s, p=0.008). Inversely, girls on the groups II and III showed higher levels of light and moderate plus vigorous physical activity and lower time spent on sedentary than girls on group IV (light: II:318.3+/-40.1 vs. III:300.3+/-51.0 vs. IV:267.7+/-53.2 min/d, p<0.001; moderate plus vigorous: II:46.2+/-18.5 vs. III:39.8+/-16.4 vs. IV:33.1+/-22.0 min/d, p=0.004, sedentary: II:1003+/-77 vs. III:1043+/-84 vs IV:1093+/-64 min/d, p<0.001). Despite chronological and bone age differences between groups (chronological age: II:10.8+/-0.9 yrs vs. III:11.3+/-0.9 yrs vs. IV:12.5+/-0.5 yrs, p<0.001), bone age: II:10.5+/-1.1 vs. III:11.3+/-1.3 vs. IV:13.6+/-1.2 yrs, p<0.001), they were similar in fat mass %, energy and calcium intake. Partial correlation adjusted for bone age and body weight revealed a negative association between tibia speed of sound and moderate plus vigorous PA (r=-0.189, p=0.018). Conclusion: During puberty girls demonstrated higher tibia and radius speed of sound at Tanner stage IV (11.2+/-0.5 yrs) than in previous stages in a time period where there is also a significant PA decrease. Contrary to others bone studies conducted with DXA measurements, in this research moderate plu
CALCULATION OF HUMAN ENERGY BALANCE TO CONTROL WEIGHT REDUCTION PROGRAMS

Romann, M., Schmidt, W.
University of Basel, Switzerland

Background: With increasing prevalence of overweight and obesity, new and efficient strategies are needed to control body weight. There is no doubt that overweight and obesity emerge from energy imbalance and that we can predict the magnitude of weight change over time if we know the daily energy balance (EB).

Objective: Therefore the purpose of this study was to determine the effect of a negative energy balance of 2.093 kJ/day (500 kcal/day) on body composition in free living conditions.

Materials and methods:
In this controlled field trial 40 healthy adult subjects (age: 43.5 ± 9.7 y; BMI 29.0 ± 3.0 kg/m²) served as an intervention (n=30) and a control group (n=10). Energy intake (EI) was estimated with a 5 day food record. Total energy expenditure (TEE) was calculated from a simultaneous 5 day assessment with the FLEX-heart rate (HR) method. Energy balance (EB) was defined as the difference between EI and TEE. The intervention program (IP) lasted 12 weeks and included nutritional advice and two structured training sessions per week. At baseline there were no statistical differences between groups for anthropometric characteristics, EI and TEE.

Results: The IP resulted in a negative EB of 1825 ± 595 kJ/day (436 ± 142 kcal/day) compared with controls (p < 0.001). These changes were caused by a reduction in EI of 946 ± 967 kJ/day (226 ± 231 kcal/day) and an increase in TEE of 879 ± 934 kJ (210 ± 223 kcal/day). Regression analysis showed that these changes in EB induced equivalent changes in body fat mass (r = 0.84). Participants of the IP lost approximately 6.7 ± 3.6 % (p < 0.001) of body weight and reduced their percent body fat by 3.8 ± 1.7 % (p < 0.001).

Conclusion: It is possible to calculate human energy balances in free living conditions using heart-rate-monitoring and diet records. This approach provides valid results and is suitable for population studies. Additionally, it is an efficient way to control IPs targeting weight loss and the prevention of weight regain for adults.

Keywords: Energy balance, energy expenditure, energy intake, overweight, weight change.

PHYSICAL ACTIVITY, FUNCTIONAL CAPACITY AND QUALITY OF LIFE IN OLDER PEOPLE

Bravo, J., Folgado, H., Raimundo, A., Tomas-Carus, P.
University of Évora, Portugal

Introduction: Evidences show a positive relationship between regular physical activity and a high physical fitness on reduction of anxiety and depression levels, improving older people’s quality of life. Maintenance of motor skills is critical to the preservation of an independent lifestyle and quality of life in elderly. The aim of the present study was to evaluate the relationship between physical activity levels, physical fitness and quality of life among institutionalized and non-institutionalized older people. Methods: Data was collected from fourteen non-institutionalized elderly (mean ± SD) age 81.43 ± 6.51 (years) dwelling in their own homes and nine institutionalized elderly (mean ± SD) age 83.89 ± 4.01 (years) living in community-residing houses for older people. Physical activity levels in a normal week were assessed in a total of 16 hours per day during two week days and weekend with the Actigraph GT1M accelerometer. Accelerations were registered every 15 seconds. Physical fitness was assessed by The Functional Fitness Test on strength, aerobic endurance, flexibility, agility, and balance variables. People’s quality of life was measured by WHOQOL-Bref. This questionnaire evaluates physical domain, psychological domain, social relations and environment. Mann-Whitney test was used to determine the differences between groups and Spearman’s rho test was used to determine correlations between variables. Results: Non-institutionalized individuals had higher light (moderate) activity levels (p = 0.008), higher aerobic endurance capacity (p = 0.000) and higher agility/dynamic balance (p = 0.007) than institutionalized people. Similar results were found on physical domain, social relations and environment (p = 0.002), (p = 0.003), (p = 0.005) of the physical activity questionnaire. Significant correlations were observed between physical activity levels and physical domain (r = 0.470, p = 0.023) and social relations (r = 0.437, p = 0.029). Physical fitness was positively correlated with physical activity for several variables as strength (r = 0.499, p = 0.018), aerobic endurance (r = 0.783, p = 0.000), flexibility (r = 0.616, p = 0.001) and agility/dynamic balance (r = 0.636, p = 0.001). Conclusion: Older people with institutional community dwelling had lower physical activity levels than non-institutionalized similar individuals. Physical activity influences older people’s functional capacity especially aerobic capacity, and quality of life in several domains. The above results suggest that caring elderly in their own homes seems to provide higher activity patterns, functional capacities and quality of life.

EFFECTS OF AN EIGHT-WEEK AEROBIC TRAINING PROGRAM ON BLOOD LIPIDS IN HYPERTENSIVE MEN EMPLOYEES

Tadibi, V., Akbari, M.
Razi University, Iran

Introduction
Overweight and hyperlipidemia is accepted as risk factors for CHD, especially in high-stress and low-activity jobs. Therefore, in this study, we investigated the effects of an eight-week aerobic training program on blood lipids in hypertensive men employee.

Methods
Sixty employees, with age range of 35-55 years, who had hyperlipidemia (LDL, TG) and hypertension (SBP > 140, and DBP > 90 mmHg) participated in this study. Subjects were divided in experimental and control group in a random manner. Subjects in the experimental group performed an eight-week moderate aerobic training program (5 days/week-1, 45 min per day); while, subjects in the control group received no training. Blood samples were taken before and after treatment in both groups to measure blood lipids. All statistical analyses were done using SPSS for windows. Statistical significance was accepted as p<0.05.

Results and Conclusion
In the experimental group, blood lipids (TC, TG, and LDL) decreased significantly; however, the levels of HDL were not increased significantly. The changes in these factors were not significant before and after treatment for the control group. The results of this study suggest that a moderate aerobic training program could decrease the levels of blood lipids in low-activity men employee.
EFFECTS OF CONTINUOUS AND INTERMITTENT PHYSICAL EXERCISE ON ENERGETIC EXPENDITURE: COMPARISON BETWEEN OBSESE AND NON-OBESE ADOLESCENTS

Lima, R., Urasaki, R., Melo, C., Wichi, R.
University of São Paulo, São Judas Tadeu University, Brazil

This study aimed to compare, regarding to energetic expenditure (EE), continuous (CE) and intermittent exercise (IE) methods. From these results it will be possible to discuss strategies of body weight loss or maintenance. Non-obese adolescents (NO-16.8 +/- 1.1 years old) and obese ones (OB-15.5 +/- 0.8 years old) were submitted to two bouts of both methods of exercise. They were evaluated: oxygen consumption (VO2), carbon dioxide production (VCO2), respiratory quotient (IRQ), blood lactate and blood glucose. These values were evaluated at baseline, before and after the exercise bouts. CE and IE were performed at thresholds 1 and 2, respectively. To identify group differences, the adolescents were compared from body composition (bioelectric impedance) and anthropometric variables (BMI and waist circumference). The variables were compared by independent student t-test, ANOVA for repeated measures and Pearson correlation, adopting p value <0.05. The main results pointed that: obese had higher body fat and waist circumference; non-obese ones had higher aerobic power. In response to exercise, CE meant energetic expenditure 8% and 24% higher in EU, and 24% in OB, from absolute and relative values; - OB showed absolute energetic expenditure from CE 13% higher than EU, but in relative values, EU showed values 18% higher than OB. EU group presented higher EE in IE (5% absolute and 32% relative). EU presented more efficient recuperation from IE intervals. It can be concluded that CE means higher EE, but EPOC turns these values similar. From these results, both methods of exercise could be good options to prevent and treat obesity.

THE COMPARISON OF SUPEROXIDE DISMUTASE (SOD) ENZYME ACTIVITY AND LIPOPROTEIN STATUS OF ATHLETES AND NON-ATHLETES

Afzalpour, M., Naghizadeh, H., Zarban, A.
1 & 2- Birjand University, 3- Birjand University of Medical Sciences, Iran

The enzyme superoxide dismutase (SOD, EC 1.15.1.1) catalyzes the dismutation of superoxide into oxygen and hydrogen peroxide. It is therefore, an important antioxidant defense in nearly all cells exposed to oxygen. Ancient (Zourkhaneh) sport is a very traditional and national sport in Iran, therefore, the purpose of this study is to compare plasma and hemoglobin SOD enzyme activity and lipoprotein status of ancient (Zourkhaneh) athletes and non-athlete individuals. SOD activity and lipoprotein status is determined through inhibiting pirogalol auto-oxidation and CHOD-PAP methods, respectively. Kruskal-Wallis and Mann-Whitney U tests were used to compare groups; and statistical significance was also considered where P<0.05. Based on the results, the hemoglobin SOD of karatists was significantly higher than ancient (Zourkhaneh) athletes and non-athlete individuals (P<0.05), but their plasma SOD was only significantly higher than non-athletes (P<0.05). It is observed that there was not a significant differences between the three groups regarding their lipoprotein status including low density (LDL) and high density (HDL) lipoprotein cholesterol, total cholesterol and triglyceride concentration (P>0.05). In addition, the maximal oxygen uptake (V02max) of karatists was significantly higher whereas their body mass index (BMI) was significantly lower than ancient (Zourkhaneh) athletes and non-athlete individuals (P<0.05). Generally, performing karate special trainings caused Karatists to obtain beneficial antioxidant system, V02max, and body composition, but it seems that the ancient (Zourkhaneh) athletes need to modify some of their training patterns for higher achievement.

EXERCISE HABITS IMPROVE PHYSICAL, COGNITIVE AND PSYCHOLOGICAL FUNCTIONS IN THE ELDERLY AT HOME

Murata, S., Murata, J.
Himeji Dokkyo University, Japan

Purpose.
We surveyed the influence of exercise habits on physical, cognitive and psychological functions in elderly inhabitants in the community, and evaluated their association.

Material and Methods.
The subjects were 181 elderly residents, aged 65 years or older, in a rural area. The subjects who answered that they regularly performed exercise for more than 30 min per week were defined as having an exercise habit, and those who answered that they did not regularly perform exercise once a week were viewed as having no exercise habit. As measurements of physical functions, we evaluated the grip, lower limb muscle strength, flexibility of the body and walking ability. As measurements of cognitive functions, we evaluated intellectual function and attentional function. As measurements of psychological functions, we evaluated subjective well-being and the degree of satisfaction with life. Statistical analysis of group measurements with and without an exercise habit was performed by analysis of covariance with adjustment for age.

Results.
Exercise habit: Eighty-one subjects performed regular exercise, and 100 did not. There was no significant difference in the male-female ratio between the 2 groups, but the difference in age was significant (p<0.01). The age of subjects in the group with was significantly lower in that without an exercise habit. With regard to physical function, 6 parameters, such as the grip strength (p<0.01), strength of the lower limb muscles (p<0.01), and walking ability (p<0.01), were significantly higher in the group with than without an exercise habit. There were significant differences in ANS (p<0.01) and TMT (p<0.01) of cognitive function between the groups with and without an exercise habit, and these parameters were higher in the former than the latter. With regard to psychological function, the subjective sense of well-being (p<0.01) and degree of daily-life satisfaction (p<0.01) were significantly higher in the group with than without an exercise habit, but there were no significant differences in the feeling of having a worthwhile life and degree of satisfaction in human relationships between the 2 groups.

Conclusion.
These results suggest an association between regular exercise and health promotion in the elderly. In particular, regular exercise may improve physical functions such as lower limb muscle strength and walking ability and inhibit an age-associated decrease in attentive function, which is useful for the prevention of falling. Regular exercise, which may also have inhibitory effects on the development of dementia and increase the mental health state, is expected to be an effective measure for care prevention.
MARKERS OF INSULIN RESISTANCE, FATNESS AND FITNESS IN GREEK PRIMARY SCHOOLCHILDREN

Christodoulou, A., Douda, H., Gika, H., Jamurtas, A., Koutsias, S., Velissaridou, A., Tokmakidis, S.
Democritus University of Thrace, Greece

Introduction.
Childhood obesity has been correlated to markers of insulin resistance later in life (Srinivasan et al. 2002). Obesity in children is also strongly associated to low cardiorespiratory fitness (Tokmakidis et al. 2006). Research evidence from cross-sectional studies indicates that markers of insulin resistance are negatively associated with high cardiorespiratory fitness in children and adolescents (Guitin et al. 2004, Ruiz et al. 2006). However, the relationship between insulin resistance and cardiorespiratory fitness appears to be largely mediated by body fatness (Ball et al. 2004). Studies examining the interaction of markers of insulin resistance and fatness and fitness in Greek schoolchildren are scarce. Thus, the aim of the present study was to investigate the independent associations among markers of insulin resistance, fatness and cardiorespiratory fitness in Greek children.

Methods:
This was a cross-sectional study of 65 children (31 males, 34 females) aged 11.4±0.4 years, from ten randomly selected primary schools in North Attica, Greece. Weight, height and waist circumference were measured. Body fat was expressed as the sum of three skinfold thicknesses (i.e., triceps, subscapular and medial calf, average of two measurements). Cardiorespiratory fitness was estimated by the 20m. shuttle run test. The studied markers of insulin resistance were fasting insulin and homeostasis model assessment (HOMA).

Results:
Bivariate correlation analyses revealed that HOMA and fasting insulin were positively associated with body fat (r=0.489 and r=0.481, respectively, p<0.005) and negatively associated with cardiorespiratory fitness (r=0.380 and r=0.362, respectively, p<0.005). In multivariate regression analyses, after adjustment for age and gender, cardiorespiratory fitness explained a significant proportion of the variance in HOMA (Beta=-0.38, SE=0.03, p<0.002) and fasting insulin variance (Beta=-0.36, SE=0.09, p<0.004); however, after additional adjustment for fatness the coefficient for cardiorespiratory fitness decreased considerably and was no more significant (p>0.05). In contrast, body fat remained independently associated with HOMA (Beta=0.335, SE=0.01, p<0.019) and fastin insulin (Beta=0.331, SE=0.03, p<0.021).

Discussion/Conclusion.
The present data indicate that in Greek children the mechanisms linking insulin resistance and low cardiorespiratory fitness are largely affected by obesity, suggesting that the metabolic consequences of excessive body fat are detectable early in life. Intervention strategies aiming at the prevention of excessive weight gain and the improvement of cardiorespiratory fitness in childhood might contribute to the prevention of the insulin resistance syndrome and its consequences later in life.

CHARACTERISTICS OF PHYSICAL PREPAREDNESS OF MILITARY PERSONNEL

Plavina, L.
National Defence Academy of Latvia, Latvia

Introduction
Physical activities are essential from providing and keeping physical preparedness and endurance. Physical working capacity is the basement of profit service and carrier of military personnel. Military personnel individually take compulsory standard physical tests. Material and methods
The target of research was giving characteristic of physical preparedness of military personnel. 120 persons were included into the examined group. The group is divided into two sub-groups: cadets (n=60) and military personnel (n=60). We analyzed harmful habits, anthropometric data, physical tests results in each group.

Results
The questionnaire data revealed that 51 person from 120 were smokers, from them 30 were cadets and 21 other military personnel. Annual physical test results were interconnected to nicotine consumption. Push-up test results in smokers group decreased over 15.4 %. Sit-up test results in non-smokers group were over 23 % higher than in smokers group. General endurance test (country cross race) was over 12 % lower in the smokers group. Analysis of anthropometric data shown that about 30 %of persons in cadets group have a body mass index above standard level: about 65 % of the military personnel group had body mass index above standard level. We have revealed correlation between body mass index and general physical endurance (cross country race), r=-0.40, p<0.006. There were 70% of persons of the examined group demonstrated a height-weight index over standard level. The pull-up physical tests results showed a negative correlation to data of the height-weight index, r=-0.40, p<0.006. Significant correlations between push-up test results and height-weight index, r=-0.27, p<0.06, cross country race and body mass index r=-0.30, p=0.043 were found. Also smoking has negative impact over physical preparedness and physical endurance. The physical tests results decreased over 13 - 22% in different tests. Smokers have worse results in pull-up test (p=0.022), in push up test (p=0.161) and in cross country race (p=0.096). There were tendencies to increasing body mass index and height-weight index over standard level for 30 % of cadets and 65 % of military personnel.

PHYSICAL PERFORMANCE AND BODY MASS INDEX IN TURKISH CYRIOT ELEMENTARY SCHOOL CHILDREN

Tinazci, C., Emiroglu, O.
Near East University, Cyprus

Physical fitness and overweight are both important health-related and skill-related parameters. Reference data from a population is important for comparisons of children with impairments, different diseases, in habilitation or rehabilitation after injuries or for talent identification. 560 children in an Elementary School in Turkish Republic of Northern Cyprus were invited and 414 subjects participated. Testing procedures were similar to the Eurofit tests, but with some modifications. The survey aimed to obtain reference data on physical performance in Turkish Cypriot children aged 9, 10 and 11. In addition, height and body mass were assessed and body mass index (BMI)
was calculated. Results show that performance increases with age both for males and females, BMI increased with age with only small differences between genders. Large variations were found within age and gender groups. The present study has provided reference data on physical performance and body size of Turkish Cypriot children.

DETERMINATION OF FACTORS THAT MOTIVATE OUTDOOR & RECREATIONAL SPORTS CONSUMER

Koçak, S., Özesen, U.
Middle East Technical University, Turkey

Introduction: In the last decade, outdoor and recreational activities, including white-water rafting, gained more attention in the sport market. One of the important issues in outdoor and recreational sports was clarification of possible factors affecting consumers to participate in outdoor and recreational sports. However, little research has been done on different aspects of outdoor and recreational sports participants in Turkey.

Purpose: Considering the importance of the improvement in sport participation, particularly in outdoor and recreational sports, this study was aimed to determine motivational factors for consumers, who involved in daily rafting trip.

Method: For the purpose of study the “motivations of the sport consumer” survey, which was originally developed by McDonald and Milne (1999), was adapted to Turkish population. The novel survey instrument included 43 items representing 13 motivation factors. It was modified in an attempt to define and portray the Turkish whitewater rafting consumers by analyzing the thirteen constructs. After application of required valid and reliable translation procedures, the survey instrument was applied to 517 (296 male, 221 female) white-water rafting trip participants during their daily rafting trip.

Results: An exploratory factor analysis was performed to determine the dimensional structure of the items and to assess the adequacy of motivational factors of rafting consumers. Maximum likelihood factor analysis was used to extract possible factors, and also oblique rotation was used to identify stable factor loadings for each item. Results of exploratory factor analysis indicated that nine dimensions (self actualization and self esteem, aggression, physical fitness, social facilitation, achievement and competition, stress release, affiliation and aesthetics, risk taking, value development) existed in 43-item and explained 56.7% of the common variance among items. Second factor analysis was performed to define the 4 sub-factors. Results demonstrated that first factor, which was “Mental well being needs”, defined 26.13 % of the common variance. The second factor under the label of “Sport based needs” defined 6.57 % of the common variance. The third factor, which included “physical fitness” construct, defined the 6.52% of the common variance and labeled as “Fitness needs”. Finally the fourth factor which was labeled as “Social well being needs” defined 5.12% of the common variance and contained the “social facilitation and affiliation” constructs.

Conclusion: The factor analysis results identified nine dimensions while the original study had 13. Additionally, the results of the second factor analysis were remarkably consistent with those observed the original form which included 4 sub factors.

DROPOUT MOTIVES IN EXERCISE

Franco, S., Pereira, L., Simões, V.
Escola Superior de Desporto de Rio Maior, Portugal

Introduction
One of the main actual concerns in Public Health is the adherence to healthy behavior exercise. Improving compliance to exercise is know as decreasing death and disability and as having many benefits in health an in fitness condition (Balady et al., 2006). The propose of this study was to identify the dropout motives in exercise and compare those motives in the variables: gender, age, marital status, professional situation, economic condition and family dimension (number of sons). Perhaps, this can allowed create strategies to light those motives, preventing the dropout and increasing exercise adherence.

Methodology
The sample was 94 subjects (46 male and 48 females) that had dropout of exercise in Lisbon’ Gyms. They answers to an interview that was developed based on the variables that we want to study. This had one specific open answer question about the dropout motives of exercise. Motives answered in the interview were grouped (5 groups) based in the literature (Fernandes, Lázaro & Vasconcelos-Raposo, 2005; Silva & Silva, 2003; Weinberg & Gould, 2001). To compare the variables of this study Chi-square test were used.

Discussion
Analysis reveals that the most frequent dropout motive was “No time to practice because of many causes”, like other studies (Fernandes, Lázaro & Vasconcelos-Raposo, 2005; Silva & Silva, 2003, Weinberg & Gould, 2001). Motives “Don’t like the instructor”, “Training schedule are not compatible with schedule work”, “No time to practice because of work”, “Don’t have economic conditions”, “There are not specific activities” and “Because of an injury” have also had one of the biggest frequencies, also like other studies Silva & Silva, 2003, Weinberg & Gould, 2001).

There were significant differences in the dropout motives between subjects of different economic conditions. Concerning the other independent variables gender, age, marital status, professional situation and family dimension (number of sons) there were not significant differences in the dropout motives.

Gyms must develop strategies to avoid dropout, for example have a large and flexible training schedule, know the activities that clients want to training and try to have those, and have quality instructors.

RELATIONSHIP BETWEEN PHYSICAL FITNESS WITH ANXIETY AND DEPRESSION OF MALE STUDENTS IN THE GUIDANCE SCHOOLS

Sadeghi Boroujerdi, S.
University of Kurdistann, Iran

Adolescence in Reason to Mutative Specific Problems and Family, Study and Social Problems have been more Exposed to Nervous Pressure Such as Anxiety and Depression. Psychological and educational researchers always like to discover new ways for Prevent and Reduce Psychological Disorders among Students.

The Purpose of this study was survey Relationship between Physical Fitness with Anxiety and Depression of Male Students in the Guidance schools.

Statistical Population Includes Students in the Guidance schools and 350 of them were participated in this Research. The Research method was based on correlation. Data Analysis Includes descriptive statistical and Pearson Coefficients Correlation. The Value of (P<0.01) was Considered as Significant.

The Results of Descriptive Statistics showed that:
1. Students had been Similar Physical Fitness and their Situation was Sub norm of Province. Thus, they hadn't Favorite Situation.
2. at Anxiety, Average Score showed that there were Rates of Anxiety and they hadn't Favorite Situation.
3. at Depression Factor, Average Score showed that there was a Little Depression in them.

Hypothesis tests Results showed that:
1. There were Significant Relationship between Physical Fitness with Anxiety and Depression in the Male Students at Guidance Schools.
2. There were Significant Relationship between Anxiety and Depression in Male Students at Guidance Schools.

EFFECTS OF TWO DIFFERENT EXERCISE PROGRAMS ON LIPID AND LIPOPROTEIN PROFILES IN OLDER WOMEN

Marques, E., Carvalho, J., Marques, F., Mota, J.
University of Porto, Portugal

It is generally accepted that cardiovascular diseases (CVD) are one of the major causes of death in industrial countries. Therefore, CVD prevention is of high concern in industrialized societies. Physical activity is widely recognized as a means for the primary prevention of CVD as well as in patients' treatment and rehabilitation. However, the accurate type and amount of exercise necessary to induce positive alterations on lipid and lipoprotein profile, as important CVD risk factors, is still a matter of debate. The purpose of this study was to compare the possible effectiveness of two physical training programs on plasma lipid and lipoprotein profile in older women.

Ninety-seven sedentary, healthy 60 to 79 years old women were randomly assigned into multicomponent training - MT (n= 49) or resistance training - RT (n= 48). The interval training program was two times per week, 45-min exercise per session, at moderate intensity during 8 months. Modified Baecke Questionnaire for Older Adults was used in order to control the activities of daily living and the 6-minutes-walk test to assess cardiovascular fitness. Plasma concentrations of total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), and triglycerides (TG) were determined after an overnight. LDL-cholesterol (LDL-C) and atherogenic coefficient were also calculated. All the aforementioned biochemical and functional variables were assessed before and after 8 months of training-based interventions.

No significant changes were observed in the amount of daily physical activity in both groups after training interventions. Both MT and RT induced significant improvements on 6-min-walk test. However, only after multicomponent training, TG, TC/HDL-C and LDL-C/HDL-C decreased significantly (3.76 ± 5.31 mg/dl, p<0.05) and no significant changes were observed in any plasma lipid and lipoprotein variables after RT.

Therefore, the main findings of the present study suggest that 8 months of MT may be more effective than RT in the induction of favorable changes in plasma lipoprotein and lipid profiles.

RELATIONSHIP BETWEEN PHYSICAL FITNESS, BODY FAT MASS AND CORONARY RISK FACTORS IN MILITARY BRAZILIAN MALES

Nascimento, R., Martinez, E., De Sã Deco Fortes, O.
FMH/UEL, Brazil

Coronary heart disease (CHD) is the primary cause of premature mortality in most modern societies. Brazil, like as the developed countries, has experienced this situation over the last years. Risk factors for CHD are influenced by physical activity and body fat mass in the general population. PURPOSE: To assess the influence of cardiorespiratory fitness (CRF) and percentage of body fat in coronary risk factors for active duty 35+ years of age Brazilian army males. METHODS: The sample analyzed consisted of 78 military men. Blood lipid profile, glycerina, lepton, adiponectin and insulin were measured after 12 hours fasting. CRF was assessed by VO2max measured by ergospirometry using the treadmill ramp test. Percentage of body fat mass (%FM) was obtained using hydrostatic weight. RESULTS: Average age was 40.0 ± 3.1 years, weight was 83.2 ± 15.6 kg, height was 176.1 ± 6.6 cm, %FM was 20.1 ± 6.0 % body mass index was 26.7 ± 4.2 kg.m-2 and CRT was 40.6 ± 9.5. CRF showed a significant and inverse correlation between serum fasting insulin concentrations (-0.580, p<0.01), lepton (-0.538, p<0.01), total cholesterol (-0.494, p<0.01), HDL-C (-0.563, p<0.01) and significant positive correlation between HDL (0.381, p<0.01). %FM showed significant positive correlation with serum fasting insulin (0.491, p<0.01), total cholesterol (0.264, p<0.05), LDL (0.293, p<0.05), triglyceride (0.268, p<0.05) and HOA-beta (0.466, p<0.001) and inverse correlation with HDL (-0.247, p<0.05). The present study also demonstrated an inverse association of CRF with %BF (0.646, p<0.01) CONCLUSION: CRF and %FM showed relationship with several coronary risk factors. Data suggest that CRF was significantly protector for coronary events even in this sample of active males. Otherwise, fat mass loss is indicated to promote protection of those events.

CARDIOPULMONARY FITNESS OF CHILDREN WITH DEVELOPMENTAL COORDINATION DISORDER IN TAIWAN

Wu, SK., Lin, CH., Tsai, CL., Li, YC.
National Taiwan Sport University, Taiwan

Background: The importance of physical fitness to general health and well-being is well documented. In particular, physical fitness of children in the world are increasingly concerned. Examination of children with developmental coordination disorder (DCD) has recently
However, the level of physical fitness in this group has not been examined in any depth. Purpose: The purpose of this study was to examine cardiorespiratory fitness of 9 to 11 year-old children with DCD in Taiwan, and also to compare with their age-matched peers. Methods: The Movement Assessment Battery for Children (MABC) test was used to identify whether children have the problems in movement coordination. 250 children aged from 9 to 11 years were recruited in this study. The cardiopulmonary tests included using the KoKo spirometry for the pulmonary functional test, 800-m run test, and the Bruce treadmill protocol. Spirometry was used to compare pulmonary function between children with DCD and non-CD. In addition, 41 children (20 children with DCD and 21 children without DCD) took part in the Bruce treadmill protocol to measure maximum oxygen consumption. Results: There were significant differences on the pulmonary function and cardiopulmonary fitness between children with DCD and non-CD. The results showed that pulmonary functions were significantly lower in children with DCD. A significantly high correlation was found between the ability of movement coordination (MABC test) and pulmonary functions. However, the correlation between pulmonary function and maximum oxygen consumption was low and there was not a significant difference. Conclusion: Pulmonary function and cardiopulmonary fitness in children with DCD were significantly lower than that of children with non-CD. However, due to the small sample size in this study, the results may not directly apply to the whole DCD population. Further studies may need to increase the sample size to examine the topic in greater depth.

**Efficacy of Physical Activity Prescription for Active Subjects Who Exercise in a Public Park**

Pádua, P., Roque, T., Panisi, P., Martins, V., Albino, J., Kanegusuku, H., Bartholomeu, T., Forjaz, C.

**School of Physical Education and Sport, University of São Paulo, Brazil**

Introduction - Public parks are commonly used by people who want to exercise for health. However, in these facilities, physical activity is usually performed without orientation and, might be performed in a wrong way. Taking into consideration the benefits that might be provided by adequate physical activity, this study analyzed the efficacy of an individualized physical activity prescription on cardiovascular health and physical fitness of subjects who already exercise in a public park in Brazil.

Methodology - Participants were initially evaluated by: a) a questionnaire about the presence of cardiovascular symptoms, diseases and risk factors; b) measurements of weight, height, waist, hip, glycemia, cholesterol, blood pressure, and heart rate; and c) measurement of aerobic fitness (stationary march), and lower body strength (vertical jump). Participants received an aerobic prescription (walk/run, 3 to 5 times/week, 30 to 50 min at moderate intensity), which was individualized based on subject’s physical fitness and time availability. After 3 to 6 months, volunteers were reevaluated, and classified as the ones who followed (F) or did not follow (NF) the prescription.

Results - None of the parameters was altered in the NF group (10 subjects, 60 +/- 2 years, 3 men), except by diastolic blood pressure that tended to decrease. On the other hand, in the F group (26 subjects, 64+2 years, 5 men), diastolic blood pressure decreased (83 +/- 2 vs. 79 +/- 2 mmHg P<0.05), total cholesterol increased (193 +/- 4 vs. 210 +/- 4 mg/dl P<0.05) and aerobic fitness increased (104 +/- 4 vs. 112 +/- 4 steps, P<0.05). With a more detailed analysis, it was observed that diastolic blood pressure decreased only in the sub-group of subjects whose values were > 90 mmHg, total cholesterol increased in the subjects with values lower than 200 mg/dl and, aerobic fitness increased in the subjects who had high initial levels. Moreover, lower body strength, even not increasing in the group as a whole, also increased in the subjects with low initial levels.

Conclusion - Based on the results, it was possible to observe that individual prescription of walk/run to subjects who already exercise without orientation was effective to improve aerobic fitness and lower body strength in subjects with low initial values of these variables, probably due to an ineffective previous training program.

**The Relations Between Gender, Age, BMI and Physically Active and Passive Cultural Attendance**

Cuypers, K., Gundersen, K.

North-Troendelag University College, Norway

Social cultural activities may be effective as fitness activities by lowering the risk of death. When studying cultural attendance among adolescents, it can be illuminating to study current research on adolescent’s participation in cultural activities is limited (Biddle et al. 2004; Glass et al. 1999). Aim of the study: The aim of the study was to investigate adolescents in physically active versus passive cultural attendance, the associations between physically active and passive cultural participation and furthermore the distribution of gender, age and BMI.

Method: Students from two municipalities and four high schools in the county of North-Troendelag, aged 13-18 year (n=71) completed a self-administered questionnaire concerning sport, physical activity and passive cultural attendance. Analyses of variance (One-way ANOVA) and Multiple linear regression assessed differences of means and values of correlation. Result: Five passive cultural activities ranked highest among adolescents including TV watching, using cell phone, listening to music, doing homework and using PC. Active cultural activities ranked sixth on the list. Mean values of the active cultural activities and the passive cultural activities associated significantly with age. Junior high school students ranked the active cultural activities highest. Senior high school students gave priority to the passive cultural activities. Students with low BMI seemed to prefer the active cultural activities. Students with high BMI preferred the passive cultural activities. The study revealed no significant association between gender and the active or the passive cultural activities. Conclusion: There was no clear opposite character between passive and active cultural attendance. Physically active high school students also attended more passive cultural activities illustrating that adolescents participate in a broad speckter of activities.

WHY PHYSICAL ACTIVITY IS NOT THE PRIORITY BEHAVIOUR IN THE LEISURE TIME OF HUNGARIAN YOUTH?

Hamar, P., Soós, I., Bidde, S., Takács, B., Huzsár, Á.
1 Semmelweis University, Budapest; 2 University of Sunderland, UK; 3 Loughborough University, UK; 4 Eötvös Loránd University, Budapest, Hungary

Inactivity became part of our modern age with a huge development in informatics and computer technology and that process developed the “homo sedens” human type. Physically passive, inactive and sedentary lifestyle correlates with the increase of the weight and the body composition. The link between the prevalence of obesity and the change in lifestyle is considered to be evident (Biddle et al., et al., 2003; Bicsérdy, 2002; Aszmann, 2000).

In this study the connection between sedentary behaviours and regular physical activity is analysed in the lifestyle context of young Hungarian people. The structure of youngsters’ leisure-time schedule is examined, in order to reveal, what is essential for the latter active lifestyle. Students free time physical activity, organized sport activity, and sedentary behaviours, like TV, video watching, using internet, playing computer games, listening to music, telephoning and reading are investigated.

Participants (N=301) were randomly selected of 13-18 year old Hungarian primary school and secondary school male (n=121, 40.2%) and female (n=180, 59.8%) students. Eastern Hungarian and Western Hungarian settlements’ and Budapest’s educational institutions were randomly and equally included in the sample.

An ecological momentary assessment, a self-report free-time diary was used for data collection (EMA; Stone & Shivman, 2002; Marshall and et al., 2003) It comprised two parts, one with participant-level variables, family-level variables and environmental-level variables. The other part of the diary included questions of the behaviour, the location and the company of students. Data was collected in 15-minute time intervals before and after school on three weekdays and one weekend day.

According to the survey of the Hungarian National Statistical Office (2003) the dominant behaviour is TV/video viewing, furthermore either listening to music and reading or socialising behaviours respectively occupy the same volume of the daily schedule as physical activity and sports altogether.

Our results show similar figures with the dominance of TV/video viewing, and other sedentary behaviours, as sitting and talking, cognitive hobbies, motorised transport, as well as computer use and phoning. These key sedentary behaviours occupy weekdays 219.2 and weekend 346.2 minutes of free time, in contrast with sports, behavioural hobbies, unstructured play, and active transport walking cycling, which take weekdays 51.4 and weekend 71.7 minutes altogether.

The Hungarian society’s contemporary surveys of physical activity show that the inactivity increased significantly among the Hungarian young people (Aszmann, 2000; Mészáros and et al., 2002; Táárf, 2004). Hoffmann (2000) also confirmed that the sport “consumption” is not a natural part of the families’ need, which also explains, why physical activity is not a priority these days in the lifestyle of the Hungarian youth. However, further investigation is suggested by analysing the daily.

BLOOD PRESSURE REDUCTION IN MEDICATED HYPERTENSE AFTER PHYSICAL TRAINING PROGRAM DEVELOPED IN ESPAÇO BEM-ESTAR OF CENPES/PETROBAS

Mello, A., Serra, R., Simõo, R.
Rio de Janeiro Federal University, Petrobras / CENPES, Brazil

Petrobras is a big company from Brazil who works with oil, gas and several new sources of energy. Security, environment and health care are constant concerns from Petrobras Company and because of that new programs were created to develop these areas. Espaço Bem-Estar (EBE) located in CENPES Unit (Rio de Janeiro) promotes health care through regular physical fitness programs in workers with some physical conditioning disabilities, like hypertension. The physical activity is indicated in hypertensive treatment and cardiovascular disease (CHOBANIAN et al., 2003; PESCATELLO, 2005). The aim of this study was to verify the blood pressure (BP) behavior after four months training on hypertensive individual medicated. Forty sedentary or untrained individuals at least one year, divided in two groups: training group (TG) (96.7±8.3 kg; 25.2±5.3% BF; 0.96±0.05 RC/Q; 31.4±4.5 ml.kg.m-1; 32±3.7 kg.m-2) and control group (CG) (97.1±8.6 kg; 26.2±5.8% BF; 0.98±0.08 RC/Q; 33.3±6.8 ml kg.m-1; 32.3±5.3 kg.m-2). All subjects did physical evaluation and the TG did three sessions together realized on Espaço Bem-Estar (EBE) in CENPES/Petrobras. The BP was measured in rest by auscultatory method pre and post-training and the days was treated by ANOVA two-way with Scheffe post hoc when necessary (p<0.05) to comparison intra and intergroups. The results showed that TG had a BP reduction of 9% in systolic BP (SBP) (P<0.05), 2.2% in diastolic BP (DBP) (p>0.05) in intra-group analyses. In comparison between CG and TG, there was significant difference in SBP in post-training, but not in DBP. We conclude that EBE program realized in CENPES/Petrobras during four months promoted reductions in BP after a training program in hypertensive medicated individuals. Our results are in agreement with previous meta-analysis (WHELTON et al., 2002) studies.

COMPARATIVE ANALYSIS BETWEEN TRAINING PROGRAMS (STRENGTH TRAINING VERSUS HIDROGYMNASTIC) IN INCREMNTING THE PHYSICAL FITNESS IN MIDDLE-AGE INDIVIDUAL OF BOTH GENERS

Carvalho, C., Silva, A., Vieira, L., Cardoso, J., Carvalho, A.
Instituto Superior da Maia, Portugal

Nowadays, there is an increase of people practising Physical Activity (PA). Its practise provides increase of Physical Fitness (PF) in the quality of life. In this scope we carried out a study that aimed to the improvement of the PF, after the application of training programs, during a period of 10 weeks. The main objectives of this study were the following ones: 1) to improve the parameters of PF; 2) to inquire about specificity in the applied programs; 3) to get multiple effects with the application of Hidrogymnastic (Hg) programs. The sample was 24 people of both genders, with an average age of 44 (12 of strength training and 12 of Hg group). The load sessions varied from 3 days of activity with 60’ duration. The evaluation of the physical fitness was in two moments. For each one of the studied components a test was used, thus: to evaluate the endurance an ergonomic bicycle was used for 10’, in flexibility the Sit & Reach; in the explosive
strength of power of upper and lower limbs the horizontal jump and medicinal ball throws tests, for the dynamic force the Leg-Press for the lower limbs and the Bench-Press for the upper limbs; for the muscular endurance the Partial up’s test and the IMC was estimated.

The analysis of the results showed the clear superiority of the ST group. However, in the Hg group were verified the gains between the two evaluation moments. There were significant gains in the two groups in the endurance test, 23.2% in the group of ST and 10.6% in the Hg group, being the latter, which presented greater gains, as expected, since this activity aims at the development of the cardiorespiratory capacity. With respect to the strength tests; it was also the Hg group that evidenced more gains, concretely in the Leg-Press where it was observed a 16.1, in the Bench-Press 8.9 and the resistant strength a 14.3% increase. The ST group only evidenced gains in the Bench-Press, with 8.9%. These higher gains can in part be justified by the imposition made in the program of Hg, in carrying out exercises with the intention of developing the strength and using appropriate equipment. We can thus conclude that the applied programs improve the PF in the majority of the tests. In what respects the specificity of the programs we can conclude, that although ST are more oriented towards the strength and the sessions of Hg towards the development of the endurance, it was the latter that evidenced more substantial gains in both capacities after training period. Such fact could be explained because this group started from very lower levels of performance. It was also possible to observe, that program of Hg trainings, using aquatic material of additional resistance with intention of developing in parallel, it was possible to get multiple effects, since after the weeks of trainings were observed improvements at the level of the resistance and the strength. This confirms that it is possible the development of these two capacities simultaneously, at least in the group that started from a relatively lower performance.

**STUDY-PROTOCOL FOR THE PILOT STUDY: PREVENTION IN THE SAND FOR PEOPLE 50+**

**Manzer, S., Wollesen, B., Mattes, K.**  
*University of Hamburg, Germany*

Due to the demographic change, which will extend people's working lives, it is necessary to lay the physical and psychological foundations. Various physiological changes during the aging process occur, which can lead to functional deficits and illness. One sided working loads and stress increase the risk of working related illnesses. The peoples motivation for behaviour modification and health prevention in leisure time is unclear.

On the basis of the BASE concept, which was designed as an university project for workplace health promotion (Wollesen et al, 2007), a new intervention program is going to be trialled on a sandy surface with the aim of preventing working related illnesses. This health promotion program integrates (1) cardiovascular training, (2) body awareness, (3) agility, (4) strength (5) social and (6) relaxation elements aiming to evaluate its efficiency under the special circumstances in the medium sand.

Methods: From April until the end of June 2008 a pilot study of the health promotion program will be undertaken. 40 participants of the age group 50+ (20 treatment, 20 control group) will be supervised during the period of 12 weeks/90min per week. Using a pre-post-design, the following tests will be undertaken: (1) Questionnaires to collect basic data and sports biography, work-related stress, physical and psychological well-being (SF 12), (2) data collection of the heart rate variability, rest, systolic blood pressure (sBP), diastolic blood pressure (dBPI and heart rate (HR) at rest using a TASK FORCE® (CNS-Systems, NEDIS). Muscle strength and flexibility of the back and trunk muscles will be tested with the CTT Pegasus® (measure and movement simulation system). The outcomes of the intervention group vs the control group will be presented and discussed.

After another 12 weeks a sustainability test will support the long-term outcome.

Expected findings: Utilising the health promotion program on the sandy surface positive effects are expected in regards to the cardiovascular system, strength of the back and trunk muscles, flexibility and physiological and psychological wellbeing.

The advantages of the sand as a focus for the prevention program is inadequately examined. The first research revealed merely publications of beach volleyball studies. The examination by Stick & Mende (2002) shows that walking in the sand provokes a proven higher cardiovascular load than walking on asphalt, whereas walking in the sand subjectively felt less demanding. The stimulative nature of the medium sand should advance the motivation of the subjects of this study to participate in the prevention programs. Participants individual deficits can be positive effected by this program.

CHANGES IN THE BODY COMPOSITION IN OVERWEIGHT AND OBESE PEOPLE FOLLOWING EXERCISE TRAINING PROGRAM AND RESTRICTED DIET

Boyadjiev, N., Moshekov, E., Muletarov, S. 
Medical University of Plovdiv, Bulgaria

The overweight is widely spread in developed countries. Obesity has reached epidemic proportions in the United States and EU. More than 60 percent of U.S. adults for example are overweight or obese (1). In Europe between 40 and 50% of males are overweight and between 10 and 20% are obese. In females these percentages are respectively 10-20 and 25-35 (2). Most of the people with a Body Mass Index over 25 are under health risk of many diseases and health conditions, including hypertension, dyslipidemia, type 2 diabetes, coronary heart disease, stroke, gallbladder disease, osteoarthritis, sleep apnea, some cancers etc. (3). The aim of this study was to evaluate the changes of some parameters of body composition in a group of 33 subjects (28.9±5.8 ys old) with overweight (BMI between 25 and 30) following a special training program and restrictive diet for a period of 8 weeks. The body mass (BM), body fats (BF), body water (BW), visceral fats (VF), and 10 skin folds were measured at the beginning of the study and at the end of each week until the end of the investigation. All the data were processed statistically by using paired t-test and were presented as mean±SD. During the study, the subjects practiced moderate training - 4 days a week, 2 hours each session. The restrictive diet was elaborated individually in accordance with the individual BW and basal metabolic rate. It was found out a 6.8% BM reduction during the eight-week period (p<0.01). The stepwise reduction of this parameter was significant in each measurement: from 84.50±20.58 kg starting BM to 80.21±19.30 kg at the end of the first week, to 79.06±16.10 kg - at the end of the eight week. BF were reduced 13.6% (p<0.001) at the end of the experiment, and the BW increased 3.6% (p<0.001). The VF which were also reduced significantly. The subcutaneous skin fold decreased 51.5% (from 27.28±11.50 to 18.00±8.10 mm at the end of the study, p<0.001) and the abdominal skin fold - 41.3% (from 30.91±12.32 to 21.86±7.26 mm, p<0.001). As a result of these changes we can conclude that the overweight people require individual managing using appropriate training program and restricted diet. This gives positive results on the body composition parameters even at the first week of dietary manipulation and applying adequate training program.

ENERGY COST AND ENERGY SOURCES DURING SIMULATED FIRE-FIGHTING ACTIVITY

Perroni, F., Tessitore, A., Lupo, C., D’Artibale, E., Cortis, C., Cignitti, L., Capranica, L.
Istituto Universitario di Scienze Motorie, Italy

Introduction
Fire-fighting is considered as an at risk job (Bos et al., 2004) implying variable working conditions and unpredictable and heavy physical demands (i.e., rescues, structural collapses, car accidents, water accidents, fire accidents, etc.). Although the protective clothing defends fire-fighters from injuries, it imposes a 23-kg extra weight (11-23 kg) and decreases the rate of heat exchange (McLellan and Selkirk, 2004). Since in the literature (Smith et al., 2001, 2005) only the high cardiac load during simulated fire-fighting tasks has been reported, this study aimed at evaluating the energy cost and energy sources of a simulated fire-fighting task.

Methods
Twenty Italian fire-fighters (age: 32±6 yrs; BW: 24.7±2.1, VO2max: 46.5±7.7 ml.kg.min-1) performed a simulated fire-fighting task (i.e., climb a firemen’s ladder and descend a 3-floor building rescuing a 20 kg child dummy, RD; run for 250 meters, R1; complete a maze in a dark chamber, DC; run for 250 meters, R2) during which their heart rate (HR; Polar, Kempele, Finland) and respiratory gases (K4, Cosmed, Italy) were continuously recorded. Blood lactate accumulation (La, Accumet, Roche, Switzerland) was evaluated at rest and at 3, 6, 9 minutes after completing the task. The overall energy requirement (VO2eq) of the task was obtained by adding the amount of VO2 during exercise above resting (VO2ex) and to the energy equivalent (1mM=3 ml.kg-1) of peak La (VO2La).

Results
During the 12.1±2.15min,s (RD: 1.22±0.25 min,s; RI: 1.33±0.25 min,s; DC: 7.3±0.31 min,s; R2: 1.32±0.24 min,s) simulated task HR increased (RD: 145±21 b.min-1, R1: 166±9 b.min-1, DC: 165±10 b.min-1, R2: 170±14 b.min-1), with the highest frequency of occurrence (80%) of peak values (184±9 beat.min-1) registered during R2. Peak La values (9.2±2.9 mM) were observed between 3 (57%) and 6 minutes of the resting period (33%). A VO2eq of 467.3±270.0 ml.min-1kg-1 VO2ex: 412.1±272.4 ml.min-1kg-1, 94±3% of total, VO2La 19.5±18.8 ml.min-1 kg-1, 6±3% of total was measured.

Conclusions
According to the literature (Smith et al., 2001, 2005), the fire-fighting task imposed a high cardiac load on fire-fighters. The high energy cost measured during the simulated fire-fighting intervention indicates that fire-fighters need an adequate fitness level to meet the requirements of their work, which especially taxes the aerobic source. Despite an appropriate fitness level is recommended (Gledhill and Jamnik, 1992), at present Italian fire-fighters do not undergo any specific training. Finally, it is imperative that fire-fighters periodically undertake fitness screenings to prevent injuries (Ide, 1998).

**BENEFICIAL IMPACT OF PUBLIC SHORT-TERM AEROBIC INTERVAL TRAINING ON MAXIMAL EXERCISE IN SEDENTARY ELDERLY SUBJECTS**

Leprêtre, PM., Vogel, T., Brechat, P., Kaltenbach, G., Berthel, M., Lonsdorfer, J.

(1) INSEP Paris, (2) CAPS-centre de Gérontologie La Robertssau Strasbourg, (3) Service de Santé Publique des Hôpitaux de Paris, France

Aging is known to be associated with a decrease in peak oxygen consumption (VO2peak) and maximal tolerated power (MTP). Regular physical exercise is most appropriate for improving aerobic capacity, but its effect in older people is still debated. The aim of this study is to determine whether a short interval training session is associated with improvements in exercise efficiency in elderly of both genders. 19 women and 16 men (65.4 ± 4.9 years) performed an incremental exercise test before and after a 9-week period of aerobic interval training (biweekly, 30 min session where 6 x 4-min at the first ventilatory threshold alternated with 1-min at the second ventilatory threshold) on a cycle ergometer. Minute ventilation (MV), O2 uptake (VO2) and CO2 output (VCO2) were breath-by-breath measured by an open-circuit metabolic cart. Before training, maximal values of MV IMWV, VO2peak, heart rate (HR), systolic blood pressure, MTP, blood lactate at MTP recovery and power at the first (pVT1) and second ventilatory thresholds (pVT2) were higher in men compared to women. Nine weeks of interval training induced a significant increase in MVV, VO2peak, MTP, pVT1 and pVT2 and decrease in systolic blood pressure in men as in women, without any significant effect on VO2peak HR values. These findings suggest that the age-related declines in aerobic capacity are attenuated by a short exercise interval training sessions in both elderly females and males.

**RETROSPECTIVE ANALYSIS OF PHYSICAL ACTIVITY PATTERNS IN PREGNANT WOMEN: EXPLORATORY STUDY**

Santos-Rocha, R., Saraiva, E.

Sport Sciences School of Rio Maior - Polytechnic Institute of Santarém, Portugal

The benefits of physical activity during a regular and healthy pregnancy are well documented and there are general guidelines for exercise prescription based on scientific research. Exercise prescription is adapted to the different phases of pregnancy. Few specific activities have been promoted by the Fitness industry. However there is a lack of information on the specific guidelines of a large group of recreational activities such as aerobics-step and strength training, which might be adapted to healthy pregnant women. Particularly, little technical documentation exists related to the real strategies of adaptation of the same activities. In practice we have been observed that the pregnancy period is a reason for the abandonment of the physical activity, including the quotidian activity. In order to better develop safe and effective exercise programs it is necessary to understand the physical activity patterns of pregnant women; the motivations for exercise during pregnancy; the reasons for the abandonment; the expectations concerning the benefits of exercise; and the characteristics of exercise. The aims of the present exploratory study was to analyse the physical activity pattern, the motivations for practising and reasons for abandonment of 150 physically active women of 30-40 years that have been pregnant before. A retrospective study was conducted in Castelo Branco region, Portugal, using an exploratory questionnaire. Subjects were pregnant 1x (61%), 2x (25%), 3x (11%), and 4x (3%), at the age of 22-26 years (46%). 44% of the subjects were physically active before getting pregnant. Concerning the participation in physical activities during pregnancy, 29% of the subjects reported a professional orientation and 62% of the subjects exercised without orientation. During pregnancy the practice of the following activities was reported: treadmill walking (18%), cycling (17%), aerobics-step (17%), stretching (16%) - 1st trimester, stretching (25%), cycling (21%), aerobics-step (15%), and walking (19%) - 2nd trimester, "preparation for the childbirth” (47%), stretching (21%), walking (15%), and strength training (13%) - 3rd trimester, postpartum recovery exercise (25%), treadmill running (13%), strength training (13%), aerobics-step (11%), and cycling (9%) - postpartum. These activities were attended 2x (56%), 3x (40%) or more times per week (4%). 30% of the subjects reported the participation in physical activities during the 1st trimester, 31% during the 2nd trimester, 20% during the 3rd trimester and 19% during the postpartum. The subjects reported that the main benefits of oriented exercise are the reduction of stress and anxiety (28%) and to improve well-being (18%). 83% of the women that participated in the study abandoned exercise during the 1st trimester and the main reasons pointed were: they were not participants before getting pregnant, they were concerned about baby health, the risk pregnancy and the inexistence of accessible resources.

**A COMPARISON OF PHYSIOLOGICAL VARIABLES BETWEEN AEROBIC DANCE AND TREADMILL RUNNING**

Edvardsen, E., Bo, K., Ingjer, F.

Norwegian School of Sport Sciences, Norway

Background: Among women, aerobic dance is one of the most popular fitness activities in the world. However, there is surprisingly scant knowledge about the physiological responses to aerobic dance, and there seem to be disagreement between researchers about training intensity and the effect of aerobic capacity, energy consumption and role of lactic acid metabolism. The aim of the present study was to compare physiological variables between aerobic dance and treadmill running in female instructors.

Methods: 14 well trained female aerobic dance instructors, mean age 31 yrs (range 20-47) and BMI 21.0 (range 17.9-23.3) underwent treadmill exercise testing for determination of maximal oxygen uptake (VO2max), maximal heart rate (HRmax) and establishment of the relationship between oxygen uptake (VO2), heart rate (HR) and blood lactate concentration (L-lactate) at different sub maximal workloads. Additionally, all participants underwent a modified lactate profile in aerobic dance corresponding to the procedure from the treadmill with and without arm work. In the end, each subject tried to reach VO2max in aerobic dance, exercising at 100% of HRmax.

Results: There was no significant difference in VO2, HR and L-lactate between aerobic dance and treadmill running at 65-95% of HRmax. There was a linear relationship between HR and VO2 from low to maximal work loads in aerobic dance, identical with running. VO2max was significantly lower (p<0.03) in aerobic dance (mean 51.1 ml kg-1 min-1) compared to treadmill running (mean 55.2 ml kg-1 min-1). Use of arm work below or above shoulder level in the aerobic dance routine did not affect the relationship between HR, VO2 and L-lactate at 65-95% of HRmax.

Conclusion: If the goal is to increase VO2max, aerobic dance seems to be as good as treadmill running for well trained advanced aerobics dance instructors. However, reaching VO2max in aerobic dance at the same level as in running seems difficult, and may result in a total lower working load during maximal interval training.

**HIGH-SENSITIVITY C-REACTIVE PROTEIN, BODY FAT AND PHYSICAL EXERCISE AMONG OLDER PEOPLE**

Martins, R., Neves, A., Veríssimo, M., Teixeira, A.

University of Coimbra, Faculty of Sport Science and Physical Education, Portugal

Introduction
Most risk factors for cardiovascular disease, like high lipid levels, hypertension, diabetes or obesity have a pro-inflammatory action and high-sensitivity C-reactive protein (hs-CRP) has been associated with increasing risk of vascular disease.

The aim of this study is to analyse how specific physical exercise programs, an enhancing cardiovascular and a strength exercise programs, are able to promote chronic adaptations in hs-CRP and the effects in global cardiovascular risk, in an elderly population.

Methods
60 women (77.53±7.99 years old) and 44 men (75.43±6.64 years old) volunteered for the study. They were evaluated in the beginning, after the exercise programs and at follow up, with an interval of 16 weeks between evaluations. Participants were subdivided into three groups: control, aerobic exercise, and strength exercise. Blood samples were collected after a 12h fasting. Hs-CRP was determined by immunonephelometry. For statistical analysis the bivariate Pearson’s correlation coefficient and MANOVA for repeated measures were used.

Results
Significant differences were identified between the three evaluations, not only for the aerobic group [F(2, 17)=4.43, p=0.03], but also for the strength group [F(2, 15)=4.13, p=0.04]. The control group did not show any significant changes between the three evaluations. Regarding the interaction between the evaluation and sex, no significant values for the aerobic, strength or control groups were identified.

The Bonferroni test did not identify significant differences between evaluations. However, when the LSD test was used, it was possible to identify a decrease between first and third evaluations in aerobic and in the strength group.

A direct relationship between hs-CRP and body mass and with body mass index was found for the women’s group. Waist circumference, waist to hip ratio and waist to stature ratio did not correlate with hs-CRP. In the men’s group no correlations were obtained.

Discussion
In the present study, hs-CRP concentration was positively associated with body mass and body mass index in the women’s group, which did not occur in the men’s group. The higher adiposity levels attained by females (88% of central adiposity against 67% of the males) could partially explain this correlation.

The physical exercise programs seemed to have had a chronic anti-inflammatory effect that was common to both sexes. The hs-CRP values decreased in both exercise groups (aerobic and strength) which did not occurred in the control group.

Current results are in accordance with other studies (1, 2) since hs-CRP concentration decreases have also been found after exercise programs. However, the fact that differences have not been visible from the first to the second but only in the third evaluation, points to a delay of the exercise effect that calls for additional research.

EFFECTS OF AEROBIC AND STRENGTH EXERCISE PROGRAMS IN THE FUNCTIONAL FITNESS OF ELDERLY PEOPLE

Martins, R., Veríssimo, M., Teixeira, A.
University of Coimbra, Faculty of Sport Sciences and Physical Education, Portugal

Introduction
When analyzing the recommendations of physical activity for healthy community-dwelling older adults, or for those who are institutionalized, the primary objective consist in maintaining functionality and independecne, with the compression of morbidity or decrease risk of chronic disease as a secondary goals (1).

The aim of this study is to characterize and analyze the way how specific physical exercise programs (cardiovascular enhancing and strength) are capable of promoting chronic adaptations in functional fitness, in an elderly population.

Methods
70 women (77.53±7.99 years old) and 44 men (75.43±6.64 years old) volunteered for the study. They were evaluated in the beginning, after the exercise programs and at follow up, with an interval of 16 weeks between evaluations. Participants were subdivided into three groups: control, aerobic exercise, and strength exercise. The Senior Fitness Test battery (2) was used to evaluate upper and lower strength, upper and lower flexibility, aerobic endurance and, agility and dynamic balance. Bivariate Pearson’s correlation coefficient and MANOVA for repeated measures were used.

Results
A statistical significant increase of lower and upper body strength between 1st and 2nd evaluations for the aerobic and the strength group was found. In the aerobic group, only men increased lower flexibility in the 2nd evaluation while in the strength group both women and men showed an improvement. The upper flexibility showed an increased from the 1st to the 3rd evaluation in the aerobic group and an increased from the 1st to the 2nd evaluation in the strength group. The velocity, agility and dynamic balance improved between 1st and 2nd evaluation for the aerobic and the strength groups. In relation to the cardiorespiratory fitness, both exercising groups showed an improvement during the exercise period, followed by a decrease after exercise cessation.

Discussion
Our data indicates that differences between genders occurred only in upper and lower flexibility, with women attaining a higher performance. Upper and lower body strength, aerobic endurance and, agility and dynamic balance were similar for both sexes. Between the 1st and the 2nd evaluation, the control group did not register any changes in the 6 functional fitness parameters evaluated. Contrarily, the strength group improved all of these during the same period as did the aerobic group, with exception for upper flexibility, in both sexes, and lower flexibility, in women. These data support the idea that cardiovascular and strength exercise, can clearly promote improvements in several functional fitness components in elderly people. These gains imply changes in the senescence process and increased in quality of life considering the importance of the physical dimension on the multiple components of the quality of life model.

THE EFFECT OF LOW-INTENSITY AEROBIC TRAINING WITH SKIN SURFACE COOLING IN HEALTHY SEDENTARY SUBJECTS

Naito, Y., Tajima, T., Shimose, R., Seki, H., Tadano, C., Yona, M., Muro, M.
Kokushikan University, Japan

(Introduction) Regular physical activity and good physical fitness are widely accepted as factors that reduce all-cause mortality and improve a number of health outcomes including weight-loss. A recent study showed that low maximal aerobic capacity is closely related to an increase in untoward cardiac events. Therefore, physical aerobic training has been proposed to reduce these events by improving aerobic capacity. In addition, the level of resistance training intensity is an important factor for skeletal muscle hypertrophy and strength gain. However, high-intensity resistance training can increase the risk of injury, especially for frail and elderly populations. Previous studies have shown that low-intensity resistance training with skin cold stimulation in target muscles causes muscle hypertrophy and strength gain. This study aimed to investigate the effect of aerobic exercise training with ergometer combined with skin surface cooling on aerobic capacity and muscle strength. (Methods) Five sedentary subjects (age 52.2 ± 2 yrs, height 165.3 ± 7.8 cm, body mass 60.2 ± 3.1 kg) participated in aerobic cycling exercise training with leg skin surface cooling. The training period was 6 wk long, including three 30-min sessions per week at an intensity of 80% AT with skin surface cooling. Maximum VO2 during ergometer cycling was measured on separate days. A skin surface cooling was applied to the quadriceps femoris muscle by circulating 5 degree water through the cooling-pads (Japan Sigmax Co.). The mean skin temperature was maintained at 25-26 degrees during exercise. (Results and Discussion) The HR during aerobic exercise was within 101-105 beats/min. Weight and weight/hip ratio decreased after low-intensity cycling training with skin surface cooling. Leg muscle volume increased by 4-8% and maximum isometric strength increased by 14-16%. Moreover, aerobic capacities seemed to improve after training in all subjects. However, there was no change in body fat % and serum total cholesterol and leptin concentrations. The combination of leg skin surface cooling with short aerobic training induces muscle strength gain and oxygen uptake, despite the low level of exercise intensity. Low intensity aerobic training with skin surface cooling may be a potentially useful method for promoting neuromuscular function and improving aerobic capacity, covering a wide range of the population, including the frail and elderly.

EFFECT OF VIBRATION IN AGONIST MUSCLES ON AUTONOMIC NERVOUS MODULATION IN ELDERLY NOVICE TAI CHI PRACTITIONERS

Hasegawa, M., Harada, T., Muro, M.
Toho University, Japan

Introduction
Tai Chi is a remarkably effective prescription exercise for the decreasing the risk of falling in senior citizens. If we could attain this effect of this exercise in a short time, it would be of great benefit in improving the health of elderly people.

We hypothesized that the quadriceps muscle vibration, when not exercising but with a stimuli of illusionary exercise, the proper accommodation of respiratory-circulation response at the time of exercise would arise.

The primary aim of this study was to examine the effect of tonic vibration stimuli, before Tai Chi Hachidannishiki (Eight Movement Tai Chi: TC8), on autonomic nervous modulation in elderly novice Tai Chi practitioners.

This study was performed with the approval of the ethics committee of Toho University.

Methods
Seventeen elderly people who regularly train in novice Tai Chi classes were recruited for this study. They were divided into two groups, nine subjects were vibration group (TVS), aged 67.8±1.9 yr. and eight subjects were control group (CONT), aged 68.3±5.1 yr.

TVS was given a stimuli (60 Hz) on each quadriceps muscles alternatively twelve times, 5 seconds per time. This protocol was performed once a day, six days a week for four weeks. Before and one month after TC8 training, ECG was measured during five minutes rest time. Also, ramp load exercise was performed in all subjects. Hemodynamics, HRV (time and frequency domain), VO2, VCO2, VE and EMG were measured during ramp pedaling exercise.

Time-frequency spectral analysis was used to analyze heart rate. P<0.05 was considered statistically significant.

Results
There was no significant difference between TVS and CONT expiration gas before and one month after TC8 training during ramp pedaling exercise. However, in TVS there was a significant increase in %VC and %FEV one month after the experiment (p<0.05). No correlation was observed in CONT. HRV-frequency domain total power (TP) and low frequency power (LFP) increased in both groups one month after the experiment. High frequency power (HFP) increased in CONT but decreased in TVS. HFP/TP ratio increased in CONT and also increased significantly in TVS (p<0.05). Also, HFP/TP ratio increased in CONT but decreased significantly in TVS (p<0.05) under quiet condition.

Conclusion
Vibration Stimuli in quadriceps muscle before exercise enhanced balance of sympathovagal modulation and decreased parasympathetic activity during exercise in elderly novice Tai Chi practitioners. These results suggest that TC8 and tonic muscle vibration stimuli might be an effective way to the properly accommodate respiratory-circulation response at the time of exercise in elderly people in a short time.

SLOW SQUAT TRAINING HAS UNFAVORABLE EFFECTS ON MUSCLE ACTIVATION AND FORCE GENERATION PATTERNS DURING CYCLING MOVEMENTS

Tanimoto, M., Hiroshi, A., Kiyoshi, S., Motohiko, M., Naokata, I.
National Institute of Health and Nutrition, Japan

It has been reported that resistance training at intensities lower than 60-65% 1RM is virtually ineffective for increasing muscle size and strength. However, the concept of enhancing exercise movement variation was not explored in these studies. When exercise movement is designed to place muscles under continuous tension throughout the exercise movement, resistance training, even with low-intensity loads of less than 60-65% 1RM, promotes muscle hypertrophy and increases strength. We previously reported that relatively low-load (~50-60%) one repetition maximum (1RM) resistance training with slow movement and tonic force generation (LST) significantly increased muscle size and strength, and the increase was comparable to that achieved with traditional high intensity (~80-85%) 1RM resistance training at a normal speed. Therefore, LST can be proposed as an effective method of resistance training to increase muscle mass and
strength without large mechanical stress. However, the movement style of LST seems much different from the dynamic sports movement. In LST, the movement speed is intentionally reduced to elude inertia action and to place muscles under continuous tension throughout the exercise movement. However, natural movements in sports and daily life use inertia effectively. LST movement is considered very specific and uncommon in natural movement in sports and daily life. Therefore, LST might have some sort of effects on dynamic sports movement.

In the present study, we investigated the effects of LST on muscle activity and force generation patterns during cycling movement as a representative dynamic sports movement. Twenty-four healthy young men without a habit of bicycle riding or regular resistance training were randomly assigned to the LST (60% 1RM load), 3s lifting and 3s lowering movements without a relaxing phase: n=8), HN (85% 1RM load, 1s lifting, 1s lowering and 1s relaxed movements: n=8) or sedentary control (CON, n=8) groups. Subjects in the training groups performed machine squat training by the assigned exercise method. Exercise sessions consisted of three sets and were performed twice a week for 13 wk. Pre and post training, muscle activation and force generation patterns during cycling movements were evaluated by the coefficient of variation (CV) of the rectified electromyographic wave (EMG) from the vastus lateralis (VL) and CV of pedaling force. Both the CV of rectified EMG and that of pedaling force were significantly decreased in the LST group (-21% and -18%, respectively), whereas there were no significant changes in either HN or CON. Such a decrease in CV in the LST group could mean that muscle activity and force generation during cycling movement have become more tonic following LST squat training intervention. It cannot be confirmed with certainty, but it is highly possible that LST training may have an unfavorable effect on dynamic sports movements.

RELATIONSHIPS AMONG ARTERIAL STIFFNESS, DAILY PHYSICAL ACTIVITY AND OTHER RELATED FACTORS IN OLDER JAPANESE MEN

Hiromi, T.
Iwate Prefectural Univ., Japan

Recent studies have demonstrated that regular aerobic exercise could reduce the age-related increase in arterial stiffness, which is a serious risk factor for cardiovascular disease (Seals, 2003). Although detailed mechanisms by which increased physical activity levels modify arterial stiffness have not yet been shown, reducing the risks of atherosclerosis by improving blood lipoprotein profiles and oxidative stress (Shimomitsu and Takanami, 1999), and/or changes in endothelium-derived vascular dilating and constricting factors such as nitric oxide, angiotensin II and endothelin-1 (ET-1) are suggested to be candidates for these mechanisms (Thijssen et al., 2008). The present study investigated the relationship between arterial stiffness (pulse wave velocity) and daily physical activity level (accelerometer), considering individual contributing factors, blood pressure, serum lipoprotein profiles (total cholesterol, low density lipoprotein cholesterol, high density lipoprotein cholesterol and triglyceride), indices of oxidative stress (malondialdehyde-modified LDL and 8-iso-prostaglandin) and ET-1 level in 84 middle-age to elderly Japanese males (61.7±12.4 years, 41-80 years). Arterial stiffness, systolic blood pressure and serum ET-1 level increased with age (P<0.01). Daily physical activity level did not correlate with either arterial stiffness or blood pressure. Arterial stiffness, systolic blood pressure and serum ET-1 level were strongly correlated with each other (P<0.01), but there were no relationships among arterial stiffness, any component of serum lipoprotein profiles or indices of oxidative stress. The elderly subjects (>60 years) in this study showed higher daily activity levels than middle-aged subjects (≤59 years) (9165±3999 steps/day, 6717±2202 steps/day, P<0.01), but the levels of body mass index (elderly: 24.3±2.9, middle-age: 24.4±3.3), percentage of fat (elderly: 23.3±7.0%, middle-age: 22.8±4.4%), and serum lipoprotein profiles in the elderly were not different from those in middle-aged subjects. These results demonstrated that although elderly Japanese men with a relatively high level of daily physical activity maintain a preferable body composition as well as serum lipoprotein profiles, they also show a higher blood pressure and greater arterial stiffness than middle-aged males. Furthermore, endothelium-derived vascular-constricting factor ET-1 showed a strong correlation with the age-related increase in arterial stiffness in this population.

COMPARISON OF A 12-WEEK THREE HOME BASED EXERCISE PROGRAMS ON PHYSIOLOGICAL CHANGES IN UNTRAINED MIDDLE-AGED AND OLDER WOMEN

Kimura, Y., Onki, K., Hisatomi, M., Konishi, F., Nakayama, M., Etsuki, T., Sato, T.
Saga University, Japan

The aim of the present study was to compare the effect of three home based exercise programs, which one could carry out by themselves at their home, on physiological and psychological variables in the females. Forty-four middle-aged and older women (66±5 yrs), without an exercise habit were randomly assigned to a resistance exercise group (RT, n=11), step exercise group (ST, n=12), the balance board exercise group (BT, n=11) and no exercise control group (CN, n=10). Body composition, VO2peak, physical fitness, bone health status, geriatric depression score (GDS), and subjective happiness were measured before and after the intervention period. Three days diet record also obtained especially intake of calcium. RT group performed five exercises for 30 min, ST group performed step exercise with the cadence of 30 times per min for 30 min, BT group performed 30 min per day using balance trainer, and all exercise groups participated two to five days per week at their home for 12 weeks.

No significant inter-group differences were recorded for pre-training physiological, physical and psychological variables. After training, a significant improvement in RT, ST and BT groups were seen in body composition variables. The % body fat significantly decreased (p<0.05) in all training groups, however, the increases were not significant across groups. In addition, the thickness of abdominal and thigh decreased (p<0.05) significantly from 15.2 mm to 14.3 mm, from 6.9 mm to 12.5 mm, respectively, in the training groups. Significant increases in estimate VO2peak were observed in only RT group (4.7±1.4 %, p<0.05) and ST group (5.7% ± 3.3%, p<0.01), and from 15.2 mm to 14.3 mm, respectively, in the training groups, however, the increases were not significant across groups. A small improvement in all exercise groups were seen in regard to bone health status (% YAM and % age matched), while no change was seen in CN group in regard to all items. A significant improvement in RT, BT and ST groups were seen in regard to subjective happiness. Subjective health degree (8.8 to 10.2%, p<0.05), everyday feeling (9.7 to 12.1%, p<0.01), human relation (7.9 to 10.8%, p<0.05) and life satisfaction degree (8.4 to 12.5%, p<0.01) were increased significantly in the training groups. GDS decreased only in RT group. No change was seen in the CN group in regard to all items.

References.
It was suggested that low-load home-based resistance exercise, step exercise and balance exercise would maintain body composition and increase muscle strength and bone health level which may be beneficial in terms of risk for and health-related diseases and osteoporosis of middle-aged and older women, and that it an available method of improving psychological items such as subjective health and degree of life satisfaction.

**FACTORS ASSOCIATED WITH EXERCISE IN THE 3RD TRIMESTER - PREGNANT WOMEN'S SOCIAL SUPPORT AND ATTITUDES**

**Haakstad, L., Voldner, N., Henriksen, T., Be, K.**

Norwegian School of Sport Sciences, Norway

Background: The current American College of Obstetrics and Gynecology (ACOG) and the Canadian Guidelines for Exercise in Pregnancy, advise the continuation of pre-pregnancy exercise activities, and recommend regular exercise for at least 15 minutes three times per week. However, studies have indicated that healthy pregnant women are insufficiently physically active and that progressively more women exceed the optimal weight gain. To date there is scant knowledge to explain why pregnant women stop exercising regularly.

Objective: To investigate characteristics associated with participation in recreational exercise in the 3rd trimester and pregnant women's social support, attitudes and barriers towards exercise. Methods: Healthy pregnant women (N=467), Oslo, Norway, answered a questionnaire at gestation week 36. Results: The most common barriers to pregnancy exercise were pregnancy complications, lack of time and practical problems due to childcare. Factors negatively associated with regular exercise in the 3rd trimester were being multiparous, high weight gain, sedentary exercise habits pre-pregnancy, urinary incontinence, lumbopelvic pain and to be on sick leave. A positive impact on health complaints and increase fitness were the most important motivational factors for regular exercise. Additionally, women who were encouraged to exercise by their physician were more likely to exercise than those who were not. Exercise habits of family and friends were not related to exercise in the 3rd trimester. Conclusion: Prevention of health complaints and pre-pregnancy exercise habits were stronger motivators for regular exercise than social support from family and friends. Physicians and midwives may play a valuable role in encouraging exercise with their patients.

**INFLUENCE OF THE COMBINATION OF BETAZ2-ADRENERGIC RECEPTOR AND ENDOTHelial NITRIC OXIDE SYNTHASE (eNOS) GENE POLYMORPHISMS ON THE RISK FOR HYPERTENSION**

University of Tsukuba, Japan

**BACKGROUND:** Hypertension is recognized as one of the major risk factors for cardiovascular disease. The beta2-adrenergic receptor (ADRB2) gene and endothelial nitric oxide synthase (eNOS) gene polymorphisms are associated with clinical cardiovascular phenotypes. Recently, the Gly16Arg of ADRB2 gene and Glu298Asp of eNOS gene polymorphisms have been reported to be related to hypertension (1,2). We hypothesized that the combination of gene polymorphisms in Gly16Arg of ADRB2 and Glu298Asp of eNOS increase a risk for hypertension. Accordingly, we determined the influence of the combination of these single-nucleotide polymorphisms (SNPs) on the risk for hypertension. **METHODS:** Four hundred and two middle-aged and older human subjects (66±7 years) participated in a cross-sectional study. We determined the genotypes of SNPs at Gly16Arg in exon 1 of ADRB2 and Glu298Asp in exon 7 of eNOS, using a TaqMan-polymerase chain reaction method. We also measured resting blood pressure. The present study determined the relationship between the blood pressure and the gene polymorphisms in Gly16Arg of ADRB2 and in Glu298Asp of eNOS. RESULTS: In gene polymorphism in Gly16Arg of ADRB2, the odds ratio for the presence of hypertension in the Gly/Gly genotype of ADRB2 compared with other genotype (Arg/Arg+Arg/Gly) was 2.87 (95%CI: 1.60-5.15, p<0.01). In gene polymorphism in Glu298Asp of eNOS, the odds ratio for the presence of hypertension in Glu/Glu genotype of NO33 compared with other genotype (Asp/Asp+Asp/Glu) was 2.79 (95%CI: 1.32-5.89, p<0.01). Interestingly, the odds ratio for the combination of Gly/Gly genotype of ADRB2 and Glu/Glu genotype of eNOS compared with the combination of Arg/Arg+Arg/Gly genotype of ADRB2 and Asp/Asp+Asp/Glu genotype of eNOS was 7.64 (95%CI: 2.88-20.29, p<0.01). CONCLUSIONS: The present study demonstrated that the combination of gene polymorphisms in Gly16Arg of ADRB2 and Glu298Asp of eNOS remarkably increase a risk for hypertension in middle-aged and older humans. These polymorphisms may be important in the health and clinical care of hypertension in middle-aged and older subjects.

**EFFECTS OF AN IRONMAN TRIATHLON ON THE DNA AS DETECTED BY THE SCGE AND CBMN CYT ASSAY**

Reichhold, S., Neubauer, O., Wagner, KH.

Faculty of Life Sciences, Austria

Background: Regular moderate physical activity is associated with various health benefits including decreased risk of cardiovascular diseases and diabetes. However, the enhanced formation of reactive oxygen species during acute and strenuous exercise can induce damage to lipids, proteins and nucleic acids. Currently there are no data available dealing with the influence of an Ironman triathlon or an exercise load of comparable duration on genomic stability. Thus, the major aim of the present study was to investigate the effect of an Ironman triathlon race (3.8 km swim, 180 km cycle, 42 km run), as a prototype of ultra-endurance exercise, on genomic stability.
DHEA ACTIVATES THE GLUCOSE METABOLISM-RELATED SIGNALLING PATHWAY IN SKELETAL MUSCLE

Sato, K., Iemitsu, M., Aizawa, K., Ajisaka, R.
University of Tsukuba, Japan

Background: Circulating dehydroepiandrosterone (DHEA) is converted to testosterone or estrogen in the target tissues. Recently, we demonstrated that skeletal muscles are capable of locally synthesizing testosterone and estrogen. Furthermore, testosterone is converted to dihydrotestosterone (DHT) by reductase, and exerts biophysiological actions through binding to androgen receptors. However, it remains unclear whether skeletal muscle can synthesize DHT from DHEA and whether these hormones affect glucose metabolism-related signalling pathway in skeletal muscles. We hypothesized that locally synthesized DHT from DHEA activates glucose transporter-4 (GLUT4) -regulating pathway in skeletal muscles. The aim of the present study was to clarify whether DHT is synthesized from DHEA in cultured skeletal muscle cells and whether these hormones affect the GLUT4-related signalling pathway in skeletal muscles.

Methods: Myoblasts of skeletal muscle were isolated from 2- to 3-day-old Sprague-Dawley rats. Muscle cells were exposed to either skeletal muscle cells and whether these hormones affect the GLUT4-related signalling pathway in skeletal muscles.

Results: The number of BN cells with MNi decreased (p<0.05) after the race, remained at a low level until 5 d post exercise and declined further to 19 d post race (p<0.01). The frequency of NPBs and Nbuds did not change immediately after the triathlon, but the number of NBP significantly declined from 2 d pre race to 19 d post exercise (p<0.05). The number of Nbuds increased after the triathlon, reaching a maximum 5 d post race (p<0.01) and decreased to basic levels 19 d after the race (p<0.01). The DNA migration (tail moment) decreased significantly (p<0.05) after the race, then increased (p<0.05), reaching a maximum 1 d post race and declined below basic levels 19 d post race (p<0.05).

Conclusion: The present study suggests that an Ironman triathlon race does not cause DNA damage as detected by the CBMN Cyt assay, but leads to increased DNA migration 1 d post race as shown in the SCGE assay; however, this marker decreased to the basic levels 5 d post race. Thus, it seems that adaptive mechanisms including the upregulation of repair mechanisms and increased capacity of the endogenous antioxidative system may prevent severe oxidative stress and long lasting DNA damage after strenuous exercise in well trained athletes.

HAPLOTYPY ANALYSIS OF A CANDIDATE GENE AS A RISK FACTOR FOR ACHILLES TENDON PATHOLOGY

Saunders, C., September, A., Schwellnus, M., Collins, M.
University of Cape Town, South Africa

There is evidence to suggest the existence of a genetic susceptibility to tendon pathology and injuries in some individuals. Recently, the COL5A1 and TNC genes have been shown to be associated with Achilles tendon pathology and the aim of this study was, therefore, to investigate other genetic risk factors associated with Achilles tendon pathology within a South African population. A candidate gene X was identified and selected based on its chromosomal location and its biological function. Ninety three patients diagnosed with Achilles tendinopathy (TEN) and 131 control (CON) subjects were genotyped for six single nucleotide polymorphisms (SNP) within this gene using the amplification refractory mutation system (ARMS) PCR method. Individually, none of the six SNP’s genotyped in this study were significantly associated with Achilles tendon pathology (SNP 1 967,2=0.16, p=0.922; SNP 2 967,2=5.50, p=0.056; SNP 3 967,2=1.44, p=0.048; SNP 4 967,2=2.46, p=0.293; SNP 5 967,2=2.39, p=0.303; SNP 6 2=0.327). The GG genotype of SNP 2 was however significantly over-represented in the TEN group (37.6%) when compared to the CON group (23.7%) (OR=2.0, 95% CI 1.1-3.5, p =0.026). In addition, preliminary data suggests that a particular haplotype within gene X is associated with Achilles tendinopathy. In conclusion, these preliminary results suggest that variants within gene X are associated with Achilles tendinopathy and, that gene X may be a third gene involved in the aetiology of this condition. We are currently in the process of securing a patent for several aspects of our research and, therefore, are unable to reveal the name of the gene used in this study.

STRONGER AND SLIMMER WITH ECCENTRIC ERGOMETER TRAINING: FUNCTIONAL, STRUCTURAL AND MOLECULAR ADAPTATIONS IN OCTOGENARIANS

Mueller, M., Breif, F., Döpp, C., Steiner, R., Büschkühl, M., Perrig, W., Hoppeler, H.
Institute of Anatomy, University of Bern, Switzerland

Introduction
Sarcopenia is characterized by the loss of muscle mass and strength as a consequence of aging. Intense Physical strength training counteracts sarcopenia. Eccentric ergometer training (EET) allows for high-load muscular training with low cardiovascular stress due to the low metabolic costs of eccentric (lengthening) contractions. Stress on single joints is minimized in EET as it is carried out at relatively high angular velocities in a closed muscle chain including multiple joints (hip, knees, ankles). Due to these unique features, EET is particularly convenient for elderly, characterized by frailty and a restricted aerobic capacity [1]. We hypothesized EET to be more effective than conventional resistance training (RET) to improve leg strength and body composition in octogenarians. Additionally we expected different adaptations on the level of muscle structure and gene expression.

Methods
Sixty-two elderly subjects (80.6±3.5 years) were randomized to one of the three training regimes (2x45 minutes per week) for three months: EET was carried out on a motor driven eccentric cycling ergometer where the appropriate matching of the eccentric target load had to be self-monitored on a screen by the subjects. RET consisted of four classical exercises for the lower extremity while control subjects (CT) did a non-physical computer based cognitive training. Subjects were tested before and after the training for functional parameters and body composition. Muscle biopsies were collected from M. vastus lateralis for the analysis of ultrastructure, fiber type composition and muscle specific quantitative gene expression.

Results
Significant improvements in maximal isometric extension strength of the legs (+8.4±1.7%), loss of body fat (-5.0±1.1%) and thigh fat content (-6.9±1.5%) as well as changes in type IIX/type II muscle fiber content (-22±14%) could be recorded exclusively for EET subjects. Relative thigh lean mass was increased with EET (+2.5±0.6%) and RET (+2.0±0.3%). EET resulted in a pronounced muscle transcriptome adaptation with an increased expression of repair/remodelling genes along with a consistent decrease of metabolic and mitochondrial genes. RET resulted in a small overall increase of most gene-transcripts.

Conclusions
EET is applicable for elderly in order to effectively improve leg strength and body composition. Gene expression analysis of thigh muscle biopsies showed a shift in mRNA expression from metabolic towards remodelling and repair genes upon EET. This result is consistent with the high mechanical and low metabolic stimulus executed by EET.

PLASTICITY OF SINGLE HUMAN SKELETAL MUSCLE FIBERS
Frese, S., Boelck, B., Pesta, D., Sailer, J., Bloch, W.
German Sport University, Cologne; Institute of Cardiovascular Research and Sport Medicine, Germany

Human skeletal muscle is characterized by an enormous plasticity for adaptation to several stimuli. During exercise there are different perturbations induced in recruited muscle cells due to mechanical, metabolic, neuronal and hormonal factors that lead to load-dependent skeletal muscle fiber type specific alterations.

The aim of this dissertation is to investigate single cell-specific gene expression with regard to the existence of different chimera of myosin heavy chains (MHC) and plasticity of single human skeletal muscle fibers.

Using Laser Microdissection and Pressure Catapulting (LMPC) several muscle fibers from vastus lateralis muscle were precisely excised without contaminations. Subsequently, quantitative RT-PCR was performed and the MHC-I, -IIA, -IIX, as well as the developmental MHC-embryonic and -perinatal genes were analysed in fast twitch fibers (FTF; IIA, IIX) and slow twitch fibers (STF; I) resulting from ATPase-staining.

However the analysis of MHC gene expression in single FTFs and STFs shows that existence of a heterogenous distribution of MHC genes.

In conclusion, single cell-specific gene expression analysis demonstrates the existence of MHC-gene chimera. Thus, LMPC in combination with Real-Time PCR offers a reliable and reproducible way for fiber type specific skeletal muscle research.

ANGIOTENSIN CONVERTING ENZYME GENE I/D POLYMORPHISM IN ELITE PORTUGUESE ATHLETES
University of Beira Interior, Portugal

Several recent works studied the genetic influence on athletic performance. ACE catalyzes the conversion of angiotensin I to angiotensin II and has an important role on heart cells promoting arterial vasosconstriction. Most published data concern to a polymorphism in the presence (insertion, I allele) or absence (deletion, D allele) of a 287-bp in intron 16 that determines ACE levels in serum and tissues, heart cells included. The insertion I allele has been reported amongst elite endurance athletes and a higher D allele frequency among those engaged in a more power-orientated sports. There have been no studies on the possible link between the ACE polymorphism and athletic performance in elite Portuguese athletes.

The aim of this research was to study the association between ACE I/D genotype and allele frequency of elite Portuguese athlete’s and athletic performance.

Forty-one (n=41) truly elite Portuguese athletes (swimmers, triathletes and track-and-field participants) were stratified by the duration of their event (short duration (<2 minutes); long duration (>20 minutes) and long and short distance athletes respectively. We compared ACE genotype and allele frequencies to eighteen (n=80) individuals representative of the general Portuguese population. Genotype determination was obtained by PCR-RFLP methods. A value of P<0.05 was considered statistically significant.

The results were grouped and analyzed statistically. Genotype frequencies (I/I versus I/D versus D/D) differed significantly between the two athlete’s groups (P=0.027) but was no different to that among sedentary controls (P>0.05). I allele frequency was 0.20 for the shorter distance athletes and 0.48 for the endurance participants. These data are consistent with an association of ACE genotype frequencies and athletic performance in different event durations.
THE SMALL HSP ALPHA B-CRYSTALLIN MEDIATES THE RESISTANCE TO APOPTOSIS INDUCED BY VEGF IN SKELETAL MUSCLE MYOBLASTS

Dimauro, I., Mercatelli, N., Ciafrè, S., Farace, M., Caporossi, D.
Rome University of Movement Sciences, Italy

A growing number of studies has shown that VEGF is expressed at appreciable level in non-vascular cells such as neuronal cells, bone, and skeletal muscle, where it can exert autocrine effects on survival and regeneration of the tissue cells. Indeed, it is well known, that under physiological stress condition, such as hypoxia and exercise, skeletal muscular cell expresses and releases VEGF. We have previously shown that myogenic cell line, stably transfected with hVEGF165 cDNA (C2C12VEGF), had an enhanced mitotic index, cell survival and resistance to apoptosis after exposure to cytotoxic concentrations of H2O2 (100-700 µM). Moreover, we identified alpha B crystalline (αBCry), a member of the small Hsp family, as possible mediator of the anti-apoptotic effect exerted by VEGF.

The main goal of this study is to clarify the role of αBCry in the modulation of apoptosis determined in the myogenic C2C12 cells by VEGF, and to define the molecular pathways involved in this process.

To this aim, we first analysed the cellular and molecular response towards H2O2-induced apoptosis in C2C12 myoblasts exposed to different concentrations of exogenous VEGF (0-10ng/ml), and then we verified if the specific silencing of αBCry by RNA interference (RNAi) could modify the apoptotic response of the C2C12VEGF cell line, expressing and releasing high amount of VEGF165 in culture medium.

The presence of VEGF in the culture medium determined a decrease of susceptibility to apoptosis induced in C2C12 myoblasts by cytotoxic concentration of H2O2. The analysis showed a reduction in cell death up to 50% in respect to control culture, with an increase in the expression of the αBCry protein, but not of the anti-apoptotic proteins Bcl-2 and Bcl-XL, which levels were not significantly modified. In addition, after specific αBCry silencing, the anti-apoptotic effect of VEGF disappeared, with a rescue of apoptosis susceptibility back to control levels.

Together, our data confirm the protective effect of VEGF on skeletal muscle cells and strongly suggest a role for this factor in muscle cell survival, beside its angiogenic activity. Moreover, we demonstrate that the small Hsp αBCry plays a key role in the molecular mechanism underlying the anti-apoptotic effect of VEGF in myoblasts.

EXPRESSION OF MYOGENIC REGULATORY FACTORS IN SATELLITE CELLS DURING 11 WEEKS OF STRENGTH TRAINING IN YOUNG HEALTHY MEN

Nilsen, T., Hansen, K., Rønnestad, B., Kvamme, N., Kadi, F., Raastad, T.
Norwegian School of Sport Sciences, Norway

The aim was to enhance our knowledge about the events associated with satellite cell activation during strength training. During development, the myogenic regulatory factors (MRF's) are essential for muscle growth, through activation and differentiation of satellite cells. In adult muscle, the role of MRF's during muscle hypertrophy is less clear. In order to assess the activation of satellite cells in response to strength training, we quantified the number of satellite cells positive for MyoD, myf-5 and myogenin and the total amount of these MRF's in muscle homogenate.

Twenty-three male subjects (18 - 40 years old) completed 11 weeks of whole body strength training. The exercise program consisted of three leg exercises and five upper body exercises. Biopsies were obtained from m. vastus lateralis and m. trapezius, before the exercise period, after two weeks, and post training. Biopsies were frozen in isopentan and stored at -80°C. Later, one piece of the biopsies was cut into 8 micrometer thick cross sections and another part was homogenised. The cross sections were double stained using the monoclonal antibody CD56 (BD Pharmigen, USA) which stains all satellite cells and polyclonal antibody against MyoD, myf-5 and myogenin (santa cruz, USA). The same antibodies were used for quantification of MRF protein levels in the cytosolic fraction of the homogenate by Western blots.

There was a significant increase in the number of satellite cells per muscle fibre after two weeks in both m. vastus lateralis (43±9%), and m. trapezius (34±10%). Thereafter the number of satellite cells was stable at this level throughout the training period. The proportion of satellite cells expressing one or more of the MRF's was generally low at baseline (2-3%) and was significantly increased after two weeks of strength training in both m. vastus lateralis (7.9±1.8%) and m. trapezius (5.4±1.0%), follow by a trend towards normalization after 11 weeks of training. There was a general trend for increased levels of MRFs in both muscles both early and late in the training period, but only the increase in MyoD by 80±35% after two weeks reached statistical significance.

MRF's role in satellite cell activation have been shown in vitro (2). Our results show an up regulation of MRF's in satellite cells along with an increase in the number of satellite cells per muscle fibres. This confirms that the satellite cells are activated in a similar way as during myogenesis when muscles are exposed to high load strength training. We have demonstrated an increase in the number of satellite cells per muscle fibre occurring already in the early stages of the training. The increase in the number of satellite cells was coincident with an increase in the number of MRF positive satellite cells and overall increased levels of MRF's in muscle homogenate.

EXAMINE ATTENTIONAL BENEFIT FOR ANALOGY LEARNING

Lam, W., Maxwell, J., Masters, R.
The University of Hong Kong, Hong Kong

Introduction

Movement analogies reduce a number of task-relevant ‘rules’ into a single ‘all encompassing biomechanical’ metaphor. A series of studies has found that analogy learners show resilient performance when required to perform both a primary motor skill and a concurrent secondary task (e.g., Liao & Masters, 2001) or make complex tactical decisions (Poolton, Masters, & Maxwell, 2006). However, stud-
Movement analogies reduce a number of task-relevant ‘rules’ into a single ‘all encompassing biomechanical’ metaphor. In general, previous studies have shown that analogy learning minimizes the accrual of explicit knowledge and imparts relatively robust performance under pressure (Liao & Masters, 2001). However, to date, investigations of analogy motor learning have been restricted to table tennis; therefore, the generalizability of the technique to other sport activities is unknown. In addition, no direct measure of attentional load under stress has been reported. Thus, our objectives were to examine the application of analogy learning in stressful situations using a modified basketball shooting task and to assess attentional change under stress using probe reaction times (PRT).

**Methods**

Analogic and explicit groups (n = 12 for each group) learned a modified basketball shooting task over 24 blocks of 20 trials, followed by a test phase (retention 1 transfer - retention 2). The participants in the explicit and analogy groups were given an instruction sheet containing eight written instructions describing the correct techniques to perform the shot or a single analogical instruction, respectively. They were told to shoot using only the instruction provided. The control group was un instructed and simply told to shoot using their own methods. Each day of learning contained 8 blocks of 20 trials. In dual-task transfer, all participants were asked to perform the shooting and secondary task (counting backward in threes) concurrently to assess the load on an attentional resource imparted by different learning conditions. Verbal reports were collected to assess the amount of task-relevant verbalizable knowledge accrued during learning.

**Results**

We found that all participants improved throughout three-days learning. However, as predicted, the analogy group reported less explicit knowledge and showed robust shooting performance under secondary concurrent task compared with the explicit and control groups.

**Discussions and conclusions**

Analogic learning is an as alternative to traditional learning (i.e., using explicit instructions), that not only shows learning speed similar to explicit learning, but also has benefits akin to implicit learning. Lowered attentional demands may be beneficial to learners when they are concurrently analyzing tactics/game situations, and performing a motor action.

**ATTENTIONAL DEMANDS OF ANALOGY LEARNERS UNDER PSYCHOLOGICAL STRESS**

Lam, W., Maxwell, J., Masters, R.

*The University of Hong Kong, Hong Kong*

**Introduction**

Movement analogies reduce a number of task-relevant ‘rules’ into a single ‘all encompassing biomechanical’ metaphor. In general, previous studies have shown that analogy learning minimizes the accrual of explicit knowledge and imparts relatively robust performance under pressure (Liao & Masters, 2001). However, to date, investigations of analogy motor learning have been restricted to table tennis; therefore, the generalizability of the technique to other sport activities is unknown. In addition, no direct measure of attentional load under stress has been reported. Thus, our objectives were to examine the application of analogy learning in stressful situations using a modified basketball shooting task and to assess attentional change under stress using probe reaction times (PRT).

**Methods**

Analogic and explicit groups (n = 12 for each group) learned a modified basketball shooting task over 24 blocks of 20 trials, followed by a test phase (retention 1 transfer - retention 2). The participants in the explicit and analogy groups were given an instruction sheet containing eight written instructions describing the correct technique to perform the shot or a single analogical instruction, respectively. They were told to shoot using only the instruction provided. In the stress transfer test, a combination of evaluation, monetary reward, and camera recording was used to increase participants’ anxiety levels. Throughout the learning and test phases, attentional load was assessed by simple verbal reaction time to an auditory tone. Explicit knowledge was assessed using verbal reports.

**Results**

Subjective anxiety, maximum and averaged heart rates were significantly higher in the transfer test than in retention, confirming the effectiveness of the stress manipulation. Analogy learners reported less explicit knowledge and demonstrated robust performance under stress. Explicit learners reported more explicit knowledge and deteriorated under stress. PRT data revealed that attentional load increased under stress for both groups of learners. Further inspection showed that attentional demand was increased by stress for movement preparation, but not for movement execution.

**Discussions and conclusions**

The results indicate that analogical instruction encourages an implicit mode of learning and prevents skill breakdown under psychological stress. Under stress, attentional demands were elevated regardless of learning mode. It appeared that decreased attentional capacity was detrimental to performance for the explicit group, but not the analogy group, suggesting that the latter's motor performance was less reliant on the availability of attentional resources.

**BEHAVIOUR PATTERNS ON BUTTERFLY SWIMMERS**

Cardoso, J., Carvalho, J., Campaniço, J., Oliveira, J., Louro, H.

*Higher Education Institute of Maia, University of Trás-os-montes e Allo Douro, Higher Institute of Rio Maior, Portugal*

The objective of this research was to analyse the most common individual behaviour pattern (IBP) of 22 butterfly swimmers, 14 males and 8 females (mean age 18, SD 1.5), above 500 FINA points (mean 609.35, SD 77.66). Hierarchical behaviors relationships over time can be found Bp. The study of BP, can give us detail information of the consolidation of any behavior, of initial behaviors (IB) responsible to develop the movement pattern, of healthy behaviors (performance), of non-healthy behaviors, of base behaviors (IB) which sustain the pattern and of satellite behaviors (two or more relative frequencies with no match in pattern). This research can make unique individual diagnostic because it can find the behaviors stability. We assume that behaviours stability is somehow relative to performance so the solution is to raise the length of the pattern and the quantity of healthy behaviors. In addition, the analysis of a complex set behaviour (event) can show particular non-healthy behaviors that are stable in time but decrease performance. The most complex (a double tree with 4 stroke phases) pattern with logical relationships on each swimmer has been selected and due to the amount of data interaction level was 0.05%. Each swimmer was recorded on a 25 meter sprint competition environment, and 5 cycles were coded using a mix system known as field format and categorical system (Anguera, 1992) composed by 8 stroke phases. The phases were code in 17 behaviors with 107 possible variations on head, body, arms, legs, hands trajectory and water line relationships. The data input was made in Ad hoc Software ButterflyV1 (Cardoso, 2007) that can give multiple and automatic output information such descriptive reports, semi-systematic and systematic reports. This data allows the import for Software Theme 5.0 (complex algorithm detection of the temporal and
MOTOR LEARNING OF ADOLESCENTS WITH AND WITHOUT DEVELOPMENTAL COORDINATION DISORDER

Purtsi, J., Havas, E., Viholainen, H., Cantell, M., Rintala, P., Ahonen, T.

Motor skills are prerequisites for engagement in physical activity and leisure. Acquisition of motor skills takes place via motor learning and therefore it is an essential part of active lifestyle. Developmental Coordination Disorder (DCD) is a movement skill disorder shown as an inability to perform age-appropriate self-care and academic tasks. DCD occurs in 5-15% of all children. The purpose of this study was to analyze the process of learning a new motor skill, eccentric bicycle pedalling, in adolescents with and without movement difficulties.

Ten male adolescents (14.9±0.5 yrs.) participated in a five week motor learning intervention that consisted of eight training sessions with a motor driven eccentric bicycle. Screening of DCD was based on the 15th percentile of the Movement Assessment Battery for Children (M-ABC2). Participants were divided into three groups; DCD-group (n=3), M-ABC2 52±19, non-DCD (n=3), M-ABC2 76±4), and active athletes (n=4); M-ABC2 90±3). The task was to resist the movement of pedals by producing a constant and steady force against the pedals. The target force level was indicated to the subjects with a visual feedback system. Force production was collected by online computer recording. The coefficient of variation (CV) [SD/Mean] multiplied by 100 was calculated from a 30 second period of force production in the beginning of every training session at the same target force and the pedal rate of 25 rpm. CV was used to describe the motor performance. CV was analyzed from the first, second, 4th, 6th, and 8th training sessions.

The results showed that the initial CV for the participants in the first training session was 27±5. CV improved (p<0.01) between the first and 2nd, 2nd and 4th, but there were no significant improvements between the 4th and 6th training sessions. The results indicated some improvement for the whole group (p<0.05) between the 6th and 8th training sessions. The groups only differed in the final training phase. DCD and non-DCD groups reached the best performance in the 8th training session (DCD 9.0±4.7; non-DCD 7.7±1.7). The active athletes had reached their best performance in the 6th training session (7.5±0.7).

The results of this study suggested that there were no group level differences in the motor learning processes between the groups. It appeared that adolescents with a milder form of DCD learn new motor skill in a similar manner as their peers. This should encourage professionals to organize motor learning interventions to improve the motor competence of DCD adolescents. The more severe the DCD, the more likely the motor learning processes were affected and thus, personalized motor training programs would be useful. Increasing our knowledge of motor learning in children and adolescents with DCD is important in order to find strategies to support their participation in everyday activities and promotion of physically active lifestyle.

CORRELATION BETWEEN PE TEACHERS’ JUDGEMENT OF MOTOR SKILL AND RESULTS OBTAINED BY MEANS OF STANDARDIZED TEST BATTERIES

Vandorpe, B., Vandendriessche, J., Pion, J., Vaeyens, R., Matthys, S., Philippaerts, R., Lenoir, M.
Ghent University, Belgium

Physical Education teachers are supposed to be able to reliably evaluate pupils’ motor competence. While physical components such as speed, flexibility or endurance are easy to evaluate in an objective and reliable way, evaluation of movement coordination is characterized by a relatively high degree of subjectivity.

The aim of this study was to compare teachers’ ratings of Flemish pupils’ motor skill with the results of established tests for motor competence (BOT2-SF1 and KTK2). Primary school PE teachers classified school children (N = 2538; boys and girls, 6-11 yrs. of age) into five categories, ranging from having low knowledge of motor learning in children and adolescents with DCD is important in order to find strategies to support their participation in everyday activities and promotion of physically active lifestyle.

INTRODUCTION

Adiposity is assuming alarming proportions in the whole western society. Most recent studies indicate that, for the first time, there are more adipose than underweight humans worldwide (Deutsches Ärzteblatt). The physical consequences of adiposity and its co-morbidities are severe and may evolve into a heavy burden, increasingly affecting the younger generation. This study however focuses on the differences in nutrition and physical activity behaviour of children from two opposing countries Germany, as an affluent society and Namibia as a developing country. The purpose of this investigation is to examine how the percentage of the population who are overweight and obese is distributed and how much it affects the physical activity and nutrition of children from these two different environments.
EFFECTS OF CONJUGATED LINOLEIC ACID AND RESISTANCE TRAINING IN RECREATIONAL ATHLETES

University of Palermo and Hospital “Villa Sofia - CTO”, Italy

Conjugated linoleic acid (CLA) is a mixture of positional and geometrical isomers of linoleic acid, that are known to possess several physiological effects such as enhancing immune response, reducing atherosclerosis risk, and inhibiting carcinogenesis. Over the last decade, the use of CLA supplement has become widespread among elite and recreational athletes because it should increase training effects, improve fat oxidation, increase energy delivery, reduce body weight, improve lipid profile, and so on. The purpose of this project is to investigate whether CLA supplementation after a resistance training session affects general markers of muscle damage, total testosterone, cortisol and sex hormone binding globulin.

In a double-blind and randomized manner 13 recreational athletes were randomly assigned to supplement their diet with 6 g per day of an sunflower oil placebo or 6 g per day of CLA for 21 days. After two weeks of wash-out, all subjects crossed over to the opposite group for an additional 21 days. The 3 weeks of supplementation were preceded and followed by a resistance training session involved 8 exercises, chosen to include all major muscle groups, consisting of 3 sets of 10 repetitions at approximately 75-80% of one-repetition maximum. Before and after the training session were drawn blood to measure the creatine phosphokinase, lactate dehydrogenase, cortisol and sex hormone binding globulin concentrations.

Measurements at baseline and after the 3 week of supplementation included body composition and strength. The results indicate that CLA supplementation during resistance training should increase the anabolic effect and decrease the catabolic effects of training on muscle protein.

BRANCHED-CHAIN AMINO ACID INGESTION MAY AMELIORATE MUSCLE SORENESS FROM INTENSE ECCENTRIC EXERCISE.

Jackman, S., Wiltard, O., Jeukendrup, A., Tipton, K.
University of Birmingham, United Kingdom

Inadequate recovery from unaccustomed exercise can limit exercise performance and also the ability to perform habitual activities. Repeated eccentric contractions or unaccustomed exercise leads to loss of muscle strength, an increase in muscle soreness and putative blood markers of muscle damage. Recently, nutritional interventions including branched-chain amino acids (BCAA) have been suggested to alleviate these symptoms. However, supplementation with BCAA has led to equivocal findings. Therefore, the purpose of this study was to examine the role of independent BCAA supplementation during recovery from intense eccentric exercise in carefully controlled trials. The study was a parallel, matched, single-blind experimental trial. Twenty-four non-weight-trained males were assigned to one of two groups: 1) supplemental group (SUP) ingested BCAA beverages (3.5g leucine, 2.1g isoleucine and 1.7g valine) (n=12); 2) placebo group (PLA) ingested artificially flavoured water (n=12). Each trial consisted of five consecutive days. Diet was controlled from day 1 until the final testing session consisting of 1.5g protein/kgBM and 55% of energy as carbohydrate, with the remainder of energy derived from fat. Eccentric exercise was performed on the morning of day 2 of each trial. Subjects performed 12 x 10 repetitions of eccentric knee extension exercise at 120% of their concentric one repetition maximum (62.6 ± 1.8kg). Supplements were consumed 30 min before and 1.5 h following exercise and twice more on day 2. On days 3 and 4 four supplements were consumed between meals. Muscle soreness, function and putative blood markers of muscle damage were assessed pre and post II, 8, 24, 48, 72 h exercise. Soreness was assessed using a visual analogue scale (mm). Muscle function was assessed using electrically-stimulated, maximal isometric contractions. Plasma creatine kinase (CK) and myoglobin concentrations were measured as putative markers of muscle damage. Muscle function decreased after the eccentric exercise at all time points post exercise in both supplementary groups (p<0.0001). The nadir of percentage force loss was observed at 48 h but the degree of force loss was unaffected by BCAA ingestion (-51 ± 3% with SUP versus -48 ± 7% with PLA). There was no effect of BCAA supplementation on CK or myoglobin. SUP resulted in a decrease in soreness of the muscle in the flexed position compared to PLA at 48 h 121 ± 3 mm vs. 32 ± 3 mm; p=0.02) and 72 h (77 ± 3 mm vs. 27 ± 4 mm; p=0.038). Overall flexed muscle soreness, expressed as area under the curve, was 10 ± 7% less for SUP compared to PLA (p=0.024). These data suggest that BCAA supplementation does not ameliorate eccentric exercise-induced decrements in muscle function or increases in repeated blood markers of muscle damage, but may alleviate muscle soreness.
FLUID AND ELECTROLYTE LOSSES IN ATHLETES DURING A DUAITHON COMPETITION

Laitano, O., Becker, G., Flores, LM., Schneider, CD.
Universidade Federal do Rio Grande do Sul, Brazil

Exercise in the heat interferes in body's ability of controlling core temperature due to high rates of heat production and heat gain by environmental physical transference. Prolonged sports events such as Duathlon, may lead the athlete to a hydroelectrolytic unbalance, mainly in a warm environment. The present study assessed sweat and blood sodium (Na+), potassium (K+) e chloride (Cl-) losses during a duathlon competition. Twelve amateur male athletes (body mass = 69.5 ± 6.7 kg, height = 174 ± 4.0 cm, age = 29.95 ± 7.78 years) took part in this study. The race took place in late December (Brazilian summer) therefore it was assumed that athletes were acclimatized to the warm weather. On the day of the race, environmental temperature was ~31°C and air relative humidity was ~51%. Blood collections were done pre and post race and sweat was collected during the race by attaching sweat patches to athlete's dorsal region. Serum [Na+] and [K+] were measured by flame photometer (Corning 400, NY, US). Serum [Cl-] was measured by colorimetric method (Hitachi U2000). Sweat [Na+], [K+], and [Cl-] were measured by an automated system (Cobas Integra). The average time to complete the race was 85.0 ± 6.57 minutes. The percentage of dehydration was 3.0 ± 0.92%. The replacement of fluid losses was 31 ± 18.7%. The sweat rate was 1.86 ± 0.56 l/h-1. Sweat Na+, K+, and Cl- concentration were 71 ± 26.05 mmol/l-1, 5.43 ± 1.98 mmol/l-1 and 58.93 ± 25.99 mmol/l-1, respectively. The total sweat loss of Na+, K+ e Cl- was 132.11 ± 62.82 mmol, 10.09 ± 5.01 mmol e 109.75 ± 58.49 mmol, respectively. The main finding of this study was that Duathlon athletes did not drink enough to replace their fluid volume losses. Important electrolytes losses occurred through sweating. However, serum electrolyte concentrations were not changed. Studies have shown that 2% dehydration decreases performance. In this study, although performance has not been assessed, athletes showed a dehydration higher than 2% which could have affected their race performance. Thus, nutritional strategies aiming an adequate fluid intake may help thermo-regulation process and race performance in a Duathlon competition.

CAN THE ADDITION OF PROTEIN TO A CARBOHYDRATE BEVERAGE IMPROVE ENDURANCE PERFORMANCE, ENHANCE RECOVERY, AND REDUCE MUSCLE DAMAGE AND SORENESS?

Breen, L., Tipton, K., Jeukendrup, A.
University of Birmingham, United Kingdom

Recommendations for endurance performance have emerged to suggest the addition of protein to a carbohydrate beverage is efficacious. However, studies reporting positive effects have been criticized for their methods, and more carefully controlled studies have found no effect. Research has suggested adding protein to a carbohydrate beverage may also attenuate muscle damage, muscle soreness and enhance recovery following endurance exercise. The aim of the present study was to investigate the impact of a carbohydrate-protein beverage on endurance performance, recovery and soreness compared to carbohydrate alone. In a double-blind, cross-over study, 9 trained cyclists (63 ± 6.9 ml/kg) completed two trials, consuming a 6% carbohydrate-only beverage (64.8 g/h carbohydrate, CHO) or a carbohydrate-protein beverage (64.8 g/h carbohydrate, 19.4 g/h protein, C+P). Exercise consisted of a 120-min steady-state cycle pre-load at 50% Wmax, followed by a time-trial designed to last ~1 h. Beverages (270mL) were consumed every 15-min of the steady-state ride. Twenty-four hours after the onset of each trial, participants returned to the laboratory for an electrically-superimposed maximum isometric strength test (MIST). Muscle soreness was rated on a visual analogue scale (VAS) on arrival at the laboratory, following the 1 h time-trial and 24 h after exercise. Blood samples were taken at these same time-points and analyzed for creatine kinase (CK) concentrations, cited as an indirect marker of muscle damage. Nutrient intake was controlled 24 h prior to, and during each of the two trials. Habitual intake was estimated to determine appropriate energy intake. During both trials participants consumed 8g/kg/d carbohydrate, 1.6g/kg/d protein, remainder of energy derived from fat, and were instructed to refrain from training 24 h prior to each trial. Mean power output sustained during the time-trial was similar in both treatments (249±40 and 243±44 W for CHO and C+P, respectively) with no significant between-group difference (P >0.05). No effect of supplement on time-to-complete the set amount of work was evident (61±6.5 and 63±7.5 min for CHO and C+P, respectively). Post-exercise MIST significantly declined from baseline values (492±40.4 Nm) for CHO and C+P(411±42.2 and 420±32.8 Nm respectively) with no significant between-group difference in the decline. Plasma CK concentrations increased significantly at 24 h post-exercise for CHO and C+P with no significant between-group difference (327±203 and 207±70 U/L in CHO and C+P respectively). Furthermore, 24 h post-exercise increases in VAS soreness were not significantly different between CHO and C+P. The findings of the present study indicate the addition of protein to a carbohydrate beverage did not improve cycle time-trial performance. Furthermore, results suggest carbohydrate-protein beverages do not ameliorate plasma CK, reduce muscle soreness or enhance the recovery of muscle function compared to carbohydrate alone.

A SHORT DAILY EXERCISE MAY LIMIT APPETITE IN RATS

Lac, G., Ebal, E., Michaux, O., Cavaliere, H.
Univ Clermont-Ferrand, France

Introduction.
Strategies used to counteract overweight include generally endurance exercise. Force-resistance exercise has not been tested yet with this objective. The aim of this study was to investigate the response of the main regulatory hormones of food intake (insulin, adiponectin, leptin, ghrelin) and corticosterone, to a short force resistance exercise.

Methods
Two groups of 16 rats, 65 days old, weighing 330 g, were constituted. A standard diet (containing Glucid: 72.2, Lipid: 7.7, Proteine: 20 % calorie) was given ad libitum. One group served as control, the second group was submitted to exercise training during 5 weeks. The applied exercise consisted of a two fold 5 series of 30 sec gripping on a grid which was alternatively put horizontally and vertically, additive loads (up to 200g) were progressively introduced. The total duration of the exercise didn’t exceed 10 min. Body composition: at the end of the five weeks training, lean and fat masses of each animal were estimated, under choral anesthesia, using dual X-ray absorptiometry, (Hologic QDR 4500A, Massy, France).
Hormones were assayed using available commercial kits following manufacturers recommendations. Results. Training reduced the rats body weight by 6.4% (456 vs 487, p = 0.001) mainly via a reduction of fat mass (- 10.5%). The total food intake during the 5 weeks was decreased by 11%. The insulin and ghrelin levels were lowered (respectively -41%, p = 0.05 and 20%, p = 0.04) while corticosterone level was increased (+ 85%, p = 0.02). Leptin and adiponectin exhibited no change. Conclusion. It appears that exercise, even of low intensity and duration, decreases the body weight via a decrease of food intake, this decrease is induced by changes on hormones that regulate food intake and limit overweight. These results show that exercise in rat is able to counteract weight gain, not through an increase in energy expenditure, but mainly through a reduction of food intake. They are symetrical to results reporting recently in youth that overweight linked to sedentarity was associated with increased calorie intake (Wiecha et al., 2006). References. Wiecha, J., Peterson, K.E., Ludwig, D.S., Kim, J., Sobol, A. and Gortmaker, S.L. (2006). When children eat what they watch: impact of television viewing on dietary intake in youth. Arch. Pediatr. Adolesc. Med. 160, 436-442.

THE EFFECT OF 14 DAYS SUPPLEMENTATION WITH A PROBIOTIC ON CIRCULATING HORMONAL, LEUKOCYTE, AND CYTOKINE RESPONSES TO PROLONGED CYCLING IN MAN

Gleeson, M.
Loughborough University, United Kingdom

Prolonged intense exercise has been associated with a transient fall in immune function that is associated with elevated levels of anti-inflammatory stress hormones and cytokines and a heavy schedule of training and competition can lead to immune impairment in athletes, with an increased susceptibility to upper respiratory tract infections (Gleeson, 2005). Probiotics could potentially modify immune function and so could be of benefit to athletes. The aim of the present study was to investigate the effects of 2 weeks of daily oral supplementation of a probiotic (Yakult) on immunoendocrine responses to a bout of prolonged cycling. With local ethics committee approval, 5 trained male cyclists mean (SD) age: 19.6 (±1.3) years, body mass 73.8 (7.6) kg, maximal oxygen uptake 56 (9) m l/ kg/min, training 10-15 h per week, completed the study which was a randomised, double blind, placebo-controlled, crossover design with a 2-week washout period. Each subject consumed 130 ml/day of Yakult probiotic beverage (PRO) or Placebo (PLA), for 2 weeks followed by a 2.5-hour cycle ergometer exercise trial at 60% of maximal oxygen uptake. Saliva (IgA) and venous blood samples were taken before exercise, immediately post-exercise, and 1 h post-exercise for blood leukocytes and lymphocyte subsets (FACScan, CELQUEST software), phorbol myrisate acetate-stimulated neutrophil oxidative burst activity and plasma hormones and cytokines. To compare the two trials a 2-way repeated measures ANOVA was used. Paired t-test post hoc analysis was used where appropriate with the Holm-Bonferonni correction.

Total leukocytes, lymphocytes, CD3+CD8+ and CD3-CD16+CD56+ cells and plasma growth hormone, IL-6 and IL-10 all increased post-exercise to a similar extent on the PRO and PLA trials. Post-exercise blood neutrophil counts and plasma ACTH were higher in the PRO trial compared with PLA (both P<0.05). CD3-CD16+ cells and the CD4+/CD8+ ratio were higher on the PRO trial (main effect of Trial, both P<0.01). Stimulated Neutrophil oxidative burst activity was reduced post-exercise to a similar extent on both treatments. Saliva IgA concentration tended to be higher on PRO than PLA (P=0.06). Thus, 2 weeks supplementation with Yakult had little to no effect on the immunoendocrine response to prolonged exercise. However, potential benefits included an increased circulating CD4+ cells and CD4+/CD8+ ratio which was evident both at rest and post-exercise. This could be interpreted as a potentially beneficial effect of Yakult supplementation for physically active individuals as CD4+ cells fall transiently following acute bouts of exercise and the CD4+/CD8+ ratio falls during prolonged periods of heavy training. A large scale trial is needed to confirm the indication from the salivary IgA data, that Yakult supplementation may boost mucosal IgA.

EFFECTS OF MACA BOOSTER FOOD SUPPLEMENT ON SPORTSMEN’S BODILY ADAPTATION TO PHYSICAL LOADS

Milasius, K., Dadelien, R., Tubelis, L., Raslanas, A.
Vilnius pedagogical university, Lithuania

INTRODUCTION

The Maca Booster food supplement (Almonds, Germany), is gaining popularity among sportsmen. Its basic component is the natural plant Lepidium meyenii (Maca). In folk medicine, maca is used to relieve fatigue, to improve metabolism, immune state and endurance, to strengthen the cardiovasculary system (1,2,3). However, these applications lack scientific substantiation. The aim of the present work was to elucidate the effects of the Maca Booster food supplement on sportsmen’s physical capacity and the morphological and biochemical composition of blood.

METHODS

The study cohort involved 18 sportsmen aged 20-22 years. They were administered five capsules of Maca Booster per day. One capsule contained 800 mg of dry maca root powder. The sportsmen were examined before Maca Booster supplementation, after 10 and 20 days of taking the supplement, and 20 days after its termination.

We established: single muscular contraction power ISMCP, and anaerobic elastic muscular power [AAMP], anaerobic glycolytic capacity (AGC), aerobic capacity. Vein blood samples were taken for morphological, biochemical and hormonal analyses.

RESULTS

Over the study period, the absolute SMCP increased from 1997.2±111.1 to 2137.5±107.7 W and the relative SMCP from 25.9±1.2 to 27.4±1.3 W/kg (p<0.05). The relative AAMP index increased from 16.3±0.3 to 17.3±0.4 W/kg (p<0.05). Working power under a 10-s stress load increased from 18.3±0.5 to 20.3±0.5 W/kg (p<0.05). The AGC index increased from 494.8±12.3 W to 530.1±11.0 W (p<0.05). Blood lactate level increased from 13.6±0.5 to 15.5±0.6 mmol/l (p<0.01). After 20 days of Maca Booster supplementation, PWC170 increased on average by 8.8 W (p<0.05).

Under 10 days of the study period the lymphocyte percentage increased from 34.8 to 39.9 %, erythrocyte sedimentation rate became significantly lower. Changes in blood creatinekinase, creatinine, uric acid and urea levels have shown that its supplementation may potentially increase bodily physical abilities.
CARBOHYDRATE INGESTION PRIOR TO SHORT DURATION HIGH-INTENSITY EXERCISE: EFFECTS OF TIMING OF INTAKE AND CARBOHYDRATE CONCENTRATION

Galloway, S., Smith, K., Lott, M., Smith, M., Toulouse, L.
University of Stirling, United Kingdom

The present study investigated 1) whether high-intensity exercise capacity could be influenced by pre-exercise blood glucose concentration (Part A), and 2) whether graded blood glucose elevation would impact upon high-intensity exercise capacity (Part B). In Part A, seventeen males, and in Part B ten males, performed an initial peak power output (PPO) test, two familiarisation trials riding to exhaustion at 90% of PPO, and 4 (for Part A) or 3 (for Part B) experimental trials involving exercise capacity tests at 90% PPO. In Part A, the 4 trials were conducted following ingestion of either a 6% CHO/electrolyte sports drink or flavour matched placebo administered 30 min (CHO30 and P30) or 2 hrs (CHO120 and P120) prior to exercise. No differences were observed between trials on the 2nd day of ingestion. In Part B, the 3 trials were performed on 3 days at different ingestion of 0%, 2% or 12% CHO solutions. In both parts of the study all trials were performed in a double blind cross-over design in the morning following and overnight fast. Diet and activity in the two days prior to exercise was recorded before the first visit and replicated on all other trials. Mood/arousal, blood glucose, lactate, and heart rate were recorded at intervals. In Part A, CHO ingestion 30 min prior to exercise significantly increased exercise capacity (mean±SD 9.0±1.9 min, P<0.05) compared with all other trials (7.7±1.5 P30, 8.0±1.7 P120, 7.9±1.9 CHO120). A significantly higher pre-exercise blood glucose was observed in the CHO30 trial (8.7±1.3 mmol.L-1, p<0.01) vs. P30 (5.0±0.3), P120 (4.7±0.7) and CHO120 (4.7±0.4). No differences were observed in mood/arousal, heart rate or blood lactate between trials. In Part B, blood glucose was significantly different (p<0.01) at the pre-exercise sample time between all trials (5.2±0.2 mmol.L-1 on 0% trial, 6.7±0.6 on 2% trial, and 8.5±1.3 on 12% trial). Exercise capacity following ingestion of the 2% CHO solution (9.2±2.1 min) compared with 0% (8.2±0.6) and 12% (8.0±1.2) solutions was not different but approached significance (p=0.09). Blood lactate was higher pre-exercise on 12% trial than 0% and 2% with no other differences observed between trials. The mean (95% CI) % improvement in exercise capacity amounts to 16.9 (9.5 to 24.2) % for CHO30 vs. P30 in Part A, and 11.9 (-1.5 to 25.3) % for 2% vs. 0% trials, and 15.0 (-0.8 to 30.8) % for 2% vs. 12% trials in Part B. In part A, improved exercise capacity in the CHO30 trial compared with all other trials appears to be linked to a higher pre-exercise blood glucose since mood changes from pre-drink to pre-exercise were not different and an equal amount of CHO was ingested on CHO30 and CHO120 trials. In part B the tendency for improved exercise capacity in the 2% trial indicates a moderate effect of elevating pre-exercise blood glucose and suggests that there may be an optimal pre-exercise glucose concentration for maximizing high-intensity exercise capacity.

EFFECTS OF L-CARNITINE L-TARTRATE SUPPLEMENTATION ON OGTT INSULIN SENSITIVITY INDICES AND EXERCISE METABOLISM IN LEAN AND OVERWEIGHT/OBESE MALES.

Galloway, S., Craig, T.
University of Stirling, United Kingdom

This study examined the effects of 14 days L-Carnitine L-Tartrate (LC) supplementation on blood glucose and insulin response to an oral glucose tolerance test (OGTT) and submaximal exercise. Sixteen male participants were recruited and assigned to two groups (lean (n=8) and overweight/obese (n=8)). After completing a first visit for a submaximal predictive exercise test, participants attended on three further occasions, in the morning after an overnight fast, for fasting blood samples and 2hr OGTT tests followed by an exercise bout (20 min at 40% of predicted VO2peak). The first test was a familiarisation trial and the final two tests were conducted two weeks apart following 14 days of ingestion of placebo (PL, 3g glucose/day) or LC (3g/day) ingested as 2 capsules 3x/day with meals. Blood was drawn at rest and at 15, 30, 45, 60, 90, and 120 minutes of OGTT and at 10 and 20 min of exercise for analysis of glucose and insulin. Data obtained were then used for determination of usual insulin sensitivity indices (HOMA-IR, AUC glucose, AUC insulin, 1st phase and 2nd phase beta cell function, estimated insulin sensitivity index, and estimated metabolic clearance rate). There was a significant difference between groups for body mass, % fat and BMI with no significant difference in age and height. Mean fasting glucose (5.4±0.2 PL, 5.5±0.2 LC, mmol/L), insulin (13.7±3.5 PL, 13.7±1.7 LC, μuU/ml) and HOMA-IR (2.6±0.6 PL, 2.7±0.4) LC were not different between trials, and no significant differences were observed between groups prior to supplementation. Analysis of the blood glucose response during the OGTT revealed no group effect but there was a time effect (p<0.01) and a trial by group interaction (p<0.01). Highest plasma glucose concentration was observed at 30 minutes in both trials but was significantly lower (p<0.05) at 30 min in the trial after LC (8.5±0.4 PL, 7.3±0.6 LC, mmol/L). AUC glucose was not different between trials but AUC insulin tended to be higher following LC (529±989 PL, 584±1032 LC, p=0.09). AUC estimated 1st phase (821±64 PL, 419±38 LC, μuU/ml and 2nd phase (106±12 PL, 132±8 LC, μuU/ml) beta-cell function were both significantly (p<0.05) greater following LC supplementation. No treatment differences were observed in glucose and insulin response to exercise but a trial by group interaction revealed that plasma glucose was lower after 10 minutes in the lean group (p<0.05) and plasma insulin higher at 20 minutes of exercise in the overweight/obese group (p<0.05). No effects of LC supplementation were observed on heart rate, VO2 or RER during the exercise task. It is concluded that LC appears to induce changes in blood glucose regulation during an OGTT that this may be driven by changes in beta-cell function, and that this response to LC supplementation is not different between lean and overweight/obese. Therefore, further investigation of carnitine action on beta-cell function is warranted.
HYDRATION STATUS OF DOG SLED DRIVERS IN THE FINNMARK DOGSLED RACE

Weydahl, A.
Finnmark University College, Norway

A continuous dog sled race across the Finnmark plateau in Norway starts in Alta at 70 degrees North, in March every year. The race goes through several checkpoints 4 to 10 hours apart, taking 5-10 days. During the race there are two compulsory stops, and a minimum resting time. The temperature during the race is normally all the time way below freezing, this and the fact that the driver are standing on the sled make it challenging for the drivers to drink. In a study done in the Iditarot dog sled race (1) it was found that the majority of mushers studied showed signs of dehydration. As a part of a project comparing physical strain during the Finnmark race and Iditarot, we wanted to study dehydration during the Finnmark race.

Six male drivers of the Finnmark dog sled race in 2007, volunteered to take urine samples the morning before start of the race, during the race and as soon as possible after the end of the race. The urine samples were analysed for urine specific gravity (Usg) by refractometer and osmolality (Uosm) by freezing point depression, at the University Hospital in Tromsø, Norway.

Dehydration was determined using the criteria of Uosm >900mOsm L-1 and Usg > 1,020.

All together we got only eighteen urine samples. From two of the musher’s we had urine samples from start and end of race. One musher giving three samples, got only half way through the race, a musher participating in the 500km class gave 5 samples. When using the criteria Uosm >900mOsm L-1 one of the musher’s were dehydrated even before the race. All the mushers had urine samples showing signs of dehydration during the race. Two of the musher’s had values below the Uosm criteria at the end of the race, even if they had shown signs of dehydration during the race. When using the criteria Usg > 1,020, three of the 6 musher’s were dehydrated before start, they showed all mild signs of dehydration throughout the race, but one musher had values below the Usg criteria at the end of the race.

The results show that the mushers at the Finnmark dog sled race show the same signs of dehydration as the mushers during the Iditarot References.

PROTEIN MODIFICATION RESPONDS TO EXERCISE INTENSITY AND ANTIOXIDANT SUPPLEMENTATION

Lamprecht, M., Oettl, K., Schwabeger, G., Hofmann, P., Greilberger, J.
Medical University of Graz, Austria

Background: Several oxidative stress related studies report that exercise and/or antioxidant supplementation can influence concentrations of carbonyl groups on protein (CP) in trained men and women (1, 2). There is also evidence that the redox state of human serum albumin (HSA) is changed in response to exercise (3).

Purpose: To assess the effects of different cycle exercise intensities and 28 week antioxidant supplementation on plasma CP concentrations and HSA modification in trained men. Methods: Trained men (n = 44, VO2max: 55 ± 5 mL o kg-1 o min-1, non-smokers, 34 ± 5 years of age) from a homogenous population of police Special Forces were randomly assigned to perform on a cycle ergometer either at 70% (n = 21) or 80% (n = 23) of individual VO2max for 40 minutes. Each group was further divided in a double blind manner to either placebo or active treatment (JPC) group.

Results: In the placebo group, CP concentrations increased at 80% VO2max IE and 30M, returning to pre-exercise concentrations by 30H (P < 0.05). At both 16 and 28 weeks, the placebo groups showed significantly higher BE- and 30H CP concentrations than the JPC groups (P < 0.05). The reduced fraction of HSA, human mercapt albumin (HMA), decreased at all 4 exercise tests at both exercise intensities IE and 30M, returning to pre-exercise values by 30H (P < 0.05). The modification of HSA was more pronounced in the 80% exercise intensity groups (P < 0.05). Supplementation had no influence on HSA.

Conclusions: These results indicate that CP concentrations increase with 80% VO2max intensity and respond to antioxidant supplementation. The JPC groups had lower baseline CP levels after 16 and 28 weeks and attenuated exercise induced CP increase. The HSA redox status is reversibly shifted to a more oxidized state by recent intense exercise, independent of antioxidant supplementation. References:

EFFECT OF SODIUM BICARBONATE SUPPLEMENTATION ON TENNIS SKILL PERFORMANCE AFTER A SIMULATED MATCH

Chia-Cheng, Y., Shih, MC., Chiang, CW., Wu, CL., Chang, CK.
Taiwan Sport University; China Medical University and Hospital, Taiwan

The accumulation of H+ is one of the major causes of fatigue. It has been shown that NaHCO3 supplementation may increase extracellular buffer capacity, reduce exercise-induced H+ accumulation, and enhance exercise performance. The aim of this study was to investigate the effect of NaHCO3 supplementation on skilled tennis performance after a simulated tennis match. Nine male college tennis players were recruited (mean age 21.78 years, height 173.11 cm, weight 67.97 kg). Each subject completed a bicarbonate trial (BIC) and a placebo trial (PLA) in a randomized order, separated by one week. Subjects performed 2 tennis skill tests before and after the simulated game in each trial. The skill test evaluated the accuracy and consistency of service and ground stroke to both sides of the court as previously described (Davey et al, 2002). The simulated match consisted of 12 games. Each game contained 36 hit balls, including forehand and backhand ground strokes and volleys. The subjects consumed NaHCO3 (0.3 g/kg) or placebo (NaCl, 0.209 g/kg, equal amount of Na) 70 min before the first skill test. Each subject also ingested 0.1g/kg NaHCO3 or 0.7g/kg NaCl after the third game of the simulated
match. Biochemical parameters in arterialized venous blood were measured by autoanalyzers. There were significant time and trial \( x \) time effects in plasma lactate concentration. Lactate concentrations were significantly increased after both trials with BIC showing higher increase (pre-match: \(1.22 \pm 0.54\), post-match: \(2.17 \pm 1.46\) in PLA, pre-match: \(1.25 \pm 0.41\), post-match: \(3.21 \pm 1.89\) mM in BIC). The significant trial, time, and trial \( x \) time effects were present in bicarbonate concentration. Bicarbonate concentration remained unchanged after PLA but was significantly elevated after BIC (pre-match: \(27.99 \pm 2.02\), post-match: \(26.37 \pm 3.50\) in PLA, pre-match: \(28.84 \pm 2.16\), post-match: \(37.98 \pm 3.95\) mM in BIC). Trial, time, and trial \( x \) time effects were significant in OxyBE. OxyBE was significantly lower after PLA (pre-match: \(2.46 \pm 1.68\), post-match: \(0.12 \pm 2.15\) mM) but was significantly elevated after BIC (pre-match: \(3.08 \pm 1.47\), post-match: \(11.36 \pm 3.70\) mM). The trial, time, and trial \( x \) time effects were also significant in blood pH. Blood pH remained unchanged after PLA but was significantly elevated after BIC (pre-match: \(7.37 \pm 0.32\), post-match: \(7.37 \pm 0.14\) in PLA, pre-match: \(7.37 \pm 0.26\), post-match: \(7.45 \pm 0.63\) in BIC). In the skill test, significant trial \( x \) time effect was present in service consistency. The service consistency was significantly decreased after the simulated match in PLA (pre-match: \(8.56 \pm 2.83\), post-match: \(5.56 \pm 3.00\)), but remained unchanged in BIC (pre-match: \(7.00 \pm 2.78\), post-match: \(6.89 \pm 3.14\)). The results suggested that NaHCO3 supplementation could increase extracellular buffer capacity and increase skilled tennis performance after a simulated match.

AWARENESS OF SPORTSMEN AND SPORT SPECIALISTS ABOUT USE AND INFLUENCE OF DRUG SUBSTANCES AND SUPPLEMENTS
Porozovs, J., Vanags, G.
Riga Teacher Training and Educational Management Academy, Latvia

The use of drug substances and supplements in professional and non-professional sport is influenced by the following factors: 1) the commercialization of professional sport, 2) the possibility to obtain drug substances and supplements, 3) information of various drug substances and supplements quasi positive effects on the results without explaining consequences of influence of these substances on the organism. Although information about influence of drug substances is accessible (Porterfield, 2007) and there are descriptions of famous sportsmen whose career have come to an end with using of doping the use of pharmaceutical substances in Latvia sports is a serious problem. One of the prevalent used groups of forbidden substances is androgen anabolic steroids. The aim of the work was to summarize and analyze the knowledge of Latvian professional sportsmen, non-professional sportsmen, sport specialists (coaches and sport teachers) and sport physicians about pharmacological drug substances and supplements, use of these substances and consequences connected with it. The questionnaire of professional sportsmen, non-professional sportsmen, sport specialists and sport physicians was carried out. The results of the questionnaire showed, that 80% professional sportsmen, 25% coaches, 17% sport physicians and 13% non-professional sportsmen have been contacted with the use of drug substances (doping). The main reasons of the use of drug substances are the necessity of endure strain for a long time, necessity to reach high results and keep good fit for a long time and often traumatism in professional sport. Nobody of secondary school sport teachers have been contact with the use of doping. The majority of questionnaire persons have been experience in the use of food supplements. The results of the questionnaire showed, that the majority of professional sportsmen, coaches and sport physicians could adequately assess the influence of drug substances on organism but the majority of non professional sportsmen have not enough knowledge about the influence of drug substances on organism and consequences of using drug substances. Interview with professional sportsmen demonstrated one of the ways of distributing pharmacological substances by companies: sportsmen receive products without of charge but they must suggest using these products for visitors of fitness clubs. Informative materials about drug substances (doping) and food supplements as well as information about influence of using these substances on organism are essential for sport organizations, fitness clubs and schools in order to obtain non professional sportsmen and students with better information about problem of using drug substances (doping) and food supplements.

MUSCLE GLYCOGEN DEPLETION AND BCAA SUPPLEMENTATION IN TRAINED RATS: CONSIDERATIONS ABOUT PURINE NUCLEOTIDE CYCLE AND MALATE-ASPARTATE SHUTTLE
University of Sao Paulo - School of Physical Education and Sport, Brazil

Introduction
BCAAs are oxidized directly in muscle during exercise. In intense activities, when glycogen stored might be depleted, BCAA carbon skeletons are oxidized and the amino groups, released by muscle in a greater extent. Fast-twitch muscle fibers seem to enhance AMP deaminase activity transporting NH3 to muscle. The aim of this study was to verify if BCAA supplementation in trained rats submitted to glycoen depletion and intense exercise influenced some reactions regarding PNC function and Malate-Aspartate Shuttle.

Methods
40 male Wistar adult rats were divided into 5 groups (BCAA, ISOleucine, LEUcine, VALine, PLAcebo) and were trained using a swimming protocol of 8 weeks, 1 hour a day, 5 days a week, with a 5 % load attached to their tails. In the sixth week, they performed anaerobic test (treadmill). Then they were given BCAA for the last 7 days (166 mg/kg weight/day). One day before the final experiment, they trained 1 hour, and were kept fasted during 24h to deplete glycogen stores. The final test consisted in swimming for 10 min without any load on their tails and then to swim with a 7 or 8% load according to their lactate threshold until fatigue. They were euthanized, blood and tissues were collected and kept in liquid N2. Muscle glycogen (MG) resistance to fatigue (s). Muscle Aspartate Amino Tranferase activity (AST), FUMurate and MALate levels were measured.

Results
Exercise performance was not different among experimental groups, regardless of their supplementation. MG was lower in LEU group when compared to PLA. FUM levels featured no differences in our experimental groups either. MAL in BCAA group was significantly higher compared to all other experimental groups. AST activity was statistically different higher in ISO group compared to PLA.

Discussion/Conclusion
Muscle contraction as observed in anaerobic metabolism activates AMPdeaminase, resulting in a higher aspartate and GTP uptake to reaminate IMP to S-AMP. This might explain a higher AST activity in ISO group. LEU group, due to leucine greater oxidation in muscle, might have higher NH3 muscle levels, leading to a PK activity enhance and thus favouring glycolysis. It seemed that some PNC cycle
and Malate-Aspartate shuttle reactions had an important role, regulating aminoacids and carbohydrate metabolism during intense exercise.

NUTRITIONAL ADVICE BASED ON REPETITIVE COMPLETION OF A FOOD DIARY CAN IMPROVE NUTRITIONAL HABITS OF YOUNG ATHLETES

Aerenhouts, D., Deriemaeker, P., Clarys, P.
Vrije Universiteit Brussel, Belgium

Introduction
Healthy dietary habits acquired at young age play an important role in sports performance and health maintenance (Meyer, 2007). Repetitive food diaries are preferred to estimate dietary habits (Willett, 1998).

Aims
To estimate the dietary habits of Flemish adolescent top track sprint athletes and to give nutritional advice towards a healthier sports diet.

Methods
According to Flemish Athletics League rankings, top 10 boys and girls of each sprint discipline were invited for voluntary participation. In summer and winter of 2006 and 2007, a 7 day food diary was administered. Individual nutritional advice was provided after each analysis, done by the same investigator using the Becel food-program BINS 3.0. Mean intake values as obtained by the four diaries were compared using the ANOVA procedure. The significance level was set at $p < .05$.

Results
The four food diaries were completed by 24 girls and 22 boys (age at start respectively 14,8 ± 1,6 and 14,7 ± 1,7 yrs). Total energy intake (TEI) did not change for both sexes. Protein intake expressed as percentage of TEI ranged between 14,7 ± 2,5% and 15,8 ± 1,8% in girls and 13,3 ± 1,6% and 14,8 ± 2,0% in boys. In girls, fat intake expressed as percentage of TEI was significantly higher in the first survey (29,0 ± 4,9%) than in the second (28,7 ± 4,4%) and fourth survey (28,8 ± 4,9%). In boys, percentage of total fat intake in the first survey (31,7 ± 5,1%) was significantly higher in the first survey than in the three following surveys.

For all macronutrients, a trend towards healthier intakes was observed. Higher intakes for fibre and polysaccharides expressed as percentage of TEI indicate better choices in carbohydrate sources. Moreover the lower percentage of total fat intake after nutritional advice is an indication of a better balanced diet. In conclusion, single nutritional advice on an individual basis has a positive effect on the adolescent athlete's diet, but repetitive advice can induce further improvements.

TRACKING OF MOTOR COORDINATION OF CHILDREN FROM THE AZORES ISLANDS

Deus, R., Monteiro, S., Bustamante, A., Fermino, R., Silva, S., Seabra, A., Garganta, R., Maia, J.
Faculty of Sports of the University of Porto, Portugal

Tracking of Motor Coordination of Children from the Azores Islands.
The aim of this study was to investigate the tracking of motor coordination in children of both genders from the Azores islands, Portugal that were followed longitudinally during 4 years. A stratified random sample of children from 7 to 10 years of age from four of the most populated islands of the Azores archipelago was chosen (142 girls and 143 boys). Annual Measurements were taken at the beginning of each academic year. Motor coordination was assessed with the KTK test battery consisting of four tests: balancing backward (BB), hopping in one leg (HO), jumping sideways (JS) and shifting platforms (SP). A general coordination score (GCS) based on the weighted sum of the four tests was also available. Intraclass correlation was used to estimate reliability. Tracking was computed in two different ways: (1) auto-correlations in each test as well as in GCS; (2) of Foulkes & Davis requiring the use of the best fitting model that describes intra-individual trajectories in inter-individual crossover over the 4 years. Systat 11 and LDA softwares were used in data analysis.

Reliability estimates ranged from 0.58 to 0.83 in all tests. Auto-correlations across the 4 time points ranged from 0.27 to 0.59 for (BB) for girls, and from 0.27 to 0.66 in boys, in JS from 0.52 to 0.63 in girls, and 0.60 to 0.74 in boys, in SP, from 0.28 to 0.44 in girls, and 0.17 to 0.52 in boys, in HO, from 0.16 to 0.74 in girls, and 0.39 to 0.73 in boys. For girls, Davis in girls ranged from 0.43 to 0.54; in boys, values ranged from 0.29 to 0.54. GCS auto-correlations ranged from 0.66 to 0.80 in girls and from 0.51 to 0.79 in boys: of Foulkes & Davis estimate was 0.59 for both gender.

In conclusion, individual coordination tests showed low to moderate values, but general coordination scores evidenced moderated to high values. There is also evidence of crossing of interindividual trajectories over the four years suggesting some random variation in coordination development that requires adequate attention from teachers of physical education. Moreover, and given that not all children develop coordination at the same rate, careful didactical programming of physical education classes must be developed so as to reach the diversified capabilities of all children.
SUBSTANCE USE AMONG TEENAGE GIRLS

Africa, E., Van Deventer, K.
Stellenbosch University, South Africa

The development of a healthy lifestyle during adolescence is a complex and evolving process. The continued integration of our global society has caused a shift in human social interaction and redefined the contexts of adolescents’ lives. Adolescents are inundated with a variety of choices at a stage of their lives where they are trying to create their own identity and are often faced with a number of crises and dilemmas. Adolescent girls grapple with life’s complexities and there is considerable evidence supporting the idea that health risk behaviours amongst adolescents is in fact mounting. Research has shown that health risk behaviours among Coloured adolescent girls prevail in Worcester, a region in South Africa.

Youth tend to engage in behaviour that has an impact on their health status and make them vulnerable to poor health. These risk behaviours include violence, cigarette smoking, alcohol and drug use and abuse, irresponsible sexual behaviours, unhealthy eating behaviours and physical inactivity that place adolescents at an increased risk for premature morbidity and mortality.

This paper explores the health risk behaviours associated with cigarette smoking and alcohol and drug use among a selected group of teenage girls. The sample population (N=1 805), between the ages of 13 and 16 years, was selected from three previously disadvantaged high schools in the Worcester region. They completed a questionnaire based on the Youth Risk Behaviour Survey (YRBS) (NCCDPHP, 2004). The results indicated that 60% of the respondents had smoked a cigarette, 65% had consumed alcohol and 11% used dagga. Substance use among teenagers is a grave concern and intensified efforts are needed to address this social ill.

This study’s results cannot be generalised, but it does indicate a possible direction for further exploration. It may also serve as a starting point for an early multi-dimensional intervention. Adolescence presents an opportune time for intervention. Not intervening at this point is to miss an ideal opportunity!

NEW TEACHING METHOD IN HURDLE RUNNING IMPROVED PERFORMANCE BETTER AMONG ELEMENTARY SCHOOL 6TH GRADERS

Otsuka, M., Ito, A., Ito, M.
Graduate School of Health and Sport Sciences, Osaka University of Health and Sport Sciences, Japan

We compared the effects of two methods of teaching elementary students in a hurdle class. One is a new method of teaching hurdle running with maximal interval run velocity and with minimal deceleration during hurdling. And it was emphasized that a forward take-off and clearing the hurdles with the trailing leg parallel to the trunk simple hurdling form and to run in a three-stride rhythm. The other is a general method of teaching hurdle running. That is, it was emphasized to run over the hurdles, trail the back leg parallel to the ground during clearance and run in a three- or five-stride rhythm with maximal interval velocity. We refer to the former method as the new teaching method and the latter as the common teaching method in this study.

We divided elementary school 6th graders (26 boys and 16 girls) who had little experience in hurdle running into experimental (13 boys and 8 girls) and control (13 boys and 8 girls) groups that were taught using the new and common methods, respectively. Each class comprised 4 days. The effects were compared as performance in pre and post-40 meter hurdle test filmed with seven cameras operating at 60 Hz. We analyzed hurdling velocity, interval run velocity, hurdling distance, step length, and hurdling time required to finish the race. The main findings were as follows:

1) The hurdle running records improved in all of the students in the experimental group (t = 7.23, p < 0.01), but in 69% of the control group (t = 1.20, n. s.).
2) Post-test hurdling velocity in both groups significantly increased (experimental vs. control group: t = -3.24, p < 0.01 vs. t = -2.57, p < 0.05), while interval run velocity significantly increased in the experimental group (t = -4.03, p < 0.01).
3) Both hurdling and landing distances significantly increased in the experimental group in the post-test (t = -3.59, p < 0.01 and t = -4.01, p < 0.01, respectively), while the control group did not (t = -1.81, n. s. and t = 1.46, n. s., respectively).
4) Hurdling time in the control group significantly decreased in the post-test (t = 2.56, p < 0.05), but the experimental group did not (t= 1.25, n. s.).

These findings suggested that the new teaching method is more effective in improving hurdle running records, hurdling velocity and interval run velocity, because all of the students ran faster after teaching with an emphasis on simple hurdling form.

EDUCATIONAL USE OF HEART-RATE-MONITORS IN PHYSICAL EDUCATION

Hengsberger, C., Payer, G., Hofmann, P.
KF-University of Graz, Medical University of Graz, Austria

Heart-rate-monitors (HRM) are widely used tools in sports and exercise training. Mostly this device is used in a purely functional approach such as to give objective information about the exercise response. Unfortunately, this approach has also been assumed for the application in physical education lessons (3). However, the educational approach should be primarily targeted in young pupils respecting the special needs of this group (1, 2). The physical education curriculum of secondary school demands to give pupils the possibility to train the perception and knowledge of their own bodies and is therefore not only characterized by a purely functional approach typical for athletic training (2). Aim of this study was therefore to develop playful applications of HRM use in physical education lessons in secondary school. Several applications were investigated in 56 pupils of a secondary school (age: 11.3 ± 0.5 yrs; height: 155.1 ± 6.0 cm; weight: 45.5 ± 10.7 kg).

1) PLAY with HRM: Lessons to become acquainted to the HRM in a playful form and to learn how to use them properly
2) LEARN with HRM: Lessons to learn about the own body’s response to various forms of exercise
3) EXERCISE HRM: Lessons to learn about classmates and teachers body’s response to various forms of exercise

For example: One lesson was called Find your feel-well-zone. Pupils performed using an effort evaluation sheet and determined their subjective heart rate related to each of seven effort pictures. In order to be able to master this task, children are supposed to assess their own bodies and judge their feelings at different heart rate values. This application type was tested in physical education lessons. Children moved for 11.6 ± 2.6 minutes with an average heart rate of 158.4 ± 10.3 beats/min (76.1% HRmax) until they valued all of the assigned pictures. Performing in this game, children had great fun to complete an age-appropriate endurance training within an aerobic intensity range, without recognizing the teacher’s intention to perform endurance training.

STORIL / PORTUGAL, 09-12 JULY 2008
COACHING EDUCATION THROUGH A VIRTUAL WORLD LEARNING ENVIRONMENT: A TEAM HANDBALL CASE IN SECOND LIFE

Lopes, A., Sequeira, P., Camerino, O., Anguera, M., Rodrigues, J.
L’Institut Nacional d’Educació Física de Catalunya - Universidade de Lleida, Espanha, Portugal

INTRODUCTION: Life Long Learning (LLL) is a concept which is with no doubt associated to the evolution of society as we know. It’s a need for a more competitive and cooperative communities, citizenship, and a more equal participative democracy. The outstanding development of new technologies and communication in the last decades in conjunction with the improvement of the well being and accessibility of and to the general people, promoted the LLL. The new technologies made LLL available for everyone, providing accessibility and knowledge achievement everywhere, anytime, about almost everything, based on Web 2.0. Nowadays, new possibility emerges everyday, based on 3D virtual worlds; where there’s a scientific need to confirm the relevance and utility of this new tool to the improvement and development of a more competitive human capital. Virtual worlds play an increasingly important role in the development of innovative and effective teaching and learning strategies. The virtual world of Second Life (SL) has the most active residents, by the distinguish and innovation of the conception of contents and for being referenced by the most distinguish higher education and research institutions development in the world.

PURPOSE: The aim of this study is to analyze the context of interaction between student and teacher, in a lecture on the 3D virtual world of SL.

METHODS: We organized a webinar in a classroom in SL provided by Beta Technologies. The students (coaches) enrolled (n=30) were selected by the highest degree in team handball coaching in Portugal, which means at least 6 years of coaching. The instrument was the channel of communication between lecture and coaches: a written chat. The chat conversation was automatically recorded in a log file. We used the method of content of analysis to analyse the chat conversation.

RESULTS AND CONCLUSIONS: (a) The most representative categories were: direct instruction, feedback and affection; (b) it was possible to verify that the majority of the interaction was direct instruction and feedback; (c) there was an easy interaction and affection among all participants that gathered a closer and active participation; (d) coaches had many simultaneous interventions related to the subject of the webinar, that could be all answered; (e) it was also possible to observe that the lecture could enhance and follow the programmed presentation and attend to consult simultaneously other resources in real time, to clarify with more precision the doubts of some students; (f) further investigation is needed to verify these qualitative results of the content analysis between the interaction of coaches and lecture in others sports and in the virtual world of Second Life and future studies should use voice to verify the interaction between students and lectures and to test the limitation of this tool in the virtual world of SL.

THE PROMOTION OF HEALTH-RELATED FITNESS IN PHYSICAL EDUCATION: COMPARISON OF 45 VERSUS 90 MINUTES PHYSICAL EDUCATION CLASSES

Marques, A., Diniz, J., Carreiro da Costa, F.
Faculty of Human Kinetics, Technical University of Lisbon, Portugal

Introduction: Physical Education (PE) is recognized as the most widely available resource for promoting physical activity (PA) among young people. In Portugal, the time allocated for PE in 7th to 9th grade is 135 minutes a week and in grades 10th to 12th is 180 minutes. Each school PE department can decide how to use this time. The PE curriculum suggests three 45 minute lessons, or two 45 minute lessons plus one 90 minute lesson during non-consecutive days of the week. However, no evidence exists to support this suggestion or to determine if it is followed.

Objective: We have conducted a case study focused on a secondary school PE department, aiming to quantify the lesson time spent by students in moderate to vigorous PA during 45 and 90 minutes classes and to determine their quality.

Methods: The quantity and the quality of PE were determined by heart rate (HR) monitoring and using the SOFIT. The HR of 4 students from 6 teachers was assessed during 6 lessons (3 of 45 minutes and 3 of 90 minutes). HR was recorded using a Polar system which scored HR at 5-second intervals. On a rotational basis, the PA levels of those students, as well as the lesson contexts in which they occurred, and teacher behaviours, were also observed and coded throughout each lesson, using momentary time sampling (SOFIT). To process this data two analysis were completed. The first analysis was made in reference to the students, establishing an individual comparison of different classes. After this, an analysis was made in relation to the teachers.

Results: The average HR was 133.5 (±18.6) for 45 and 130.6 (±8.6) for 90 minutes classes. The results from SOFIT and HR monitoring showed that the teachers have dedicated 59.6% and 56.5% of their class time in activities with moderate to vigorous intensity, respectively to 45 and to 90 minute lessons. In 45 minute class lessons, 16.8% of the time was dedicated to the promotion of fitness and 32% to games. These percentages are superior to those of the 90 minutes class lessons 14.7% and 28.3%, respectively. As for PA intensity, despite the fact that there were no significant differences between the 45 and 90 minutes class lessons, it could be observed that during 45 minutes there is a tendency for student HR to exceed 140 bpm for a longer time period. The results of the cluster analysis showed that games were the activities that characterize classes with moderate to vigorous intensity. A HR between 140-160 bpm is correlated with the time dedicated to fitness (r=0.64).

Conclusion: No differences were found between the 45 and 90 minute class periods, suggesting that from a pedagogical viewpoint, both options are adequate. From the SOFIT it was possible to verify that the activities with vigorous intensity happen in the periods in which the teacher had that intention, namely in the periods of fitness exercises and games. Thus, as for all teaching activities, the intensity of classes requires planning by PE teachers.
The burnout syndrome in Slovenian PE teachers
Markelj, N.
University of Ljubljana, Faculty of Sport, Slovenia

People, working in professions with intense involvement with other people, are continuously exposed to factors that threaten their psychological and physical stability. The chronic stress finally leads to burnout, a state of physical and emotional exhaustion as well as attitudinal change. Among others, teacher profession is one of the most threatening. Burnout syndrome has a large negative influence on teachers' state of mind and consequently on pedagogical work and educational process. In Slovenia, the burnout syndrome has not been thoroughly researched among teachers yet, and there is no study among PE teachers. The aim of this work is to explore the burnout syndrome among Slovenian PE teachers, focusing on the impact of sociodemographic factors, stressors, and strategies for coping with stress. The study sample consists of 54 PE teachers, selected on voluntary basis. They answered the questionnaire, consisted of 4 parts: (1) personal data and data about the work environment, (2) Maslach burnout inventory, which assesses emotional exhaustion (feeling drained and tired), depersonalization (impersonal response toward students) and personal accomplishment (feelings of incompetence and ineffectiveness), (3) stressors scale and (4) strategies for coping with stress. The basic statistical analyses were conducted, followed by the comparison with research results of Slovenian and some other foreign countries. The results show that Slovenian PE teachers are less burnt out than Slovenian teachers in general, the statistical differences are significant. We assume that those differences relate to different personal traits and different strategies for coping with stress. The majority of PE teachers listed as strategies for coping with stress sport activities, psychological relaxation (SPA, meditation, talking about problems with important others...) and good preparation for classes. Nevertheless, the assumption cannot be confirmed because no research has been done yet in that direction. The most influential stressors for PE teachers are the complex and demanding work, students' bad working habits, involvement in different obligations at once, educational reforms and great responsibility for others. Further research of prevention programmes are pointed out.

Poster presentations (PP)

PP-PE02 Physical Education 2

The level of parents' education in the question of the correct bearing formation for the preschool age children.
Kozakevich, I.
Daugavpils University, Latvia

Nowadays there is a very serious problem of children's health formation in the preschools. Insufficient physical development, weakness of muscles and ligamentary system, disbalance of muscles and different transgressions of normal movement stereotype - these are the reasons of serious disturbances of children's bearing, and in Latvia they are observed more and more often in the preschools. The data of health statistics and medicine technology state agency in 2006 about 3-14 year-old children, scoliosis and other disturbances of weight bearing show that every year the number of children with scoliosis or other disturbances of bearing grows. The number of children with scoliosis grows 30.5 of 1000 examined children of corresponding age in 2006, compared to 28.4 children in 2005 (disturbances of bearing kyphosis deflected spine 0.5%, lordosis 0.2%, correct bearing 14.3%).

The prophylaxis of motion system's early disturbances of preschool age children is an important medical, pedagogical, economical and social problem. To make children's health sound and robust educators, parents and medical workers have to collaborate. The solution of this problem depends on values in the family, on the level of erudition of parents and educators and in the conditions of health, on the healthy way of life in the family and on that fact if the adults understand their responsibility in respect of children in the question of their health. The limited level of knowledge and acquirements in the question of health is a serious obstacle in the solution of this task and in the question of health protection.

The aim of the study was to clarify the level of parents' and educators' theoretical and practical knowledge about the problems of formation of children's bearing and their attitude towards them. Study of literature, analysis and questionnaires have been used as researching methods. To clear up the theoretical and practical knowledge of parents in the formation of children's bearing the questionnaire has been conducted. The questionnaire of Yuri Bokovsky has been taken as a basis. The parents of 3-7 year-old children have participated in the survey. Three hundred and eighty parents have been questioned.

The results of the questionnaire showed, that the parents have not got enough knowledge in the question of the formation of correct bearing. Only 8.6% of the questioned parents have the high level of knowledge. 31.6% of the parents have the mean level, but 59.8% have the low level of knowledge. This study let us to conclude that educational direction provides systemization of knowledge and first of all forms the attitude to the problem.

Hyperactivity and attention deficiency among elementary schoolchildren in comprehensive schools
Shklarenko, A., Kovalenko, T., Anisimova, T., Pashkova, L., Zadnepryanova, A.
The Slavonic-on-the Kuban State Teacher Training University, Volgograd State University, Russia

Hyperactive-child syndrome accompanied with attention deficiency is the main reason of school dysadaptation. There are three types of the disorder: syndrome combining both hyperactivity and attention deficiency, attention deficiency syndrome without hyperactivity and hyperactive-child syndrome without attention deficiency. Developing of effective preventive and rehabilitation measures for such children is one of the live issues of child and adolescent remediation. The aim of our research is to detect the occurrence of the syndrome among the pupils of primary schools in Slavyansk-on-the Kuban and Volgograd. A special questionnaire for parents was developed to detect the hyperactive-child syndrome among 5-15 year-old children and teenagers (Zavadenko N.N., 2005).

During the survey 1467 parents, whose children attended 39 primary schools in Slavyansk-on-the Kuban and Volgograd were questioned. Before participating in our survey only 14% of parents believed that their children need the consultation of a neurologist because...
of serious cognitive dysfunction and behavioral problems. Parents did not see any specialist though, explaining their actions by business, fear that everybody would know about the visit to the doctor and their child would suffer social ostracism. About 19, 9% parents thought that their child had real problems with studies and behavior. They took the view that these problems would disappear when the children grew up without any help. Finally 66,1% of parents fully denied that their children had any psychoneurological problems and rejected any psychologist consultancy or medical assistance and said that they could manage the problem without any help.

According to our research 10% of primary schoolchildren have clinical presentations of the hyperactive-child syndrome. The structure of mostly slight psychopathic disorders allows us to claim that these disorders have organic nature. We can’t help mentioning the fact that 56% of parents have changed their opinion and strongly intended to see a psychoneurologist.

BIOMEDICAL PROVISION OF PHYSICAL TRAINING FOR PRIMARY SCHOOLCHILDREN
Kovalenko, T., Shklarenko, A., Ulyanov, D.
Volgograd State University, Russia

Introduction.
Recently physiologists have faced some problems connected with organization and biomedical provision of PT-lessons for primary schoolchildren. These problems were caused by growing discrepancy between school physical education demands for higher level of health advocacy on the one hand and absence of scientific knowledge for successful development and implementation of new technologies on the other hand.

Our research is aimed to find the proper system of biomedical provision of physical training for primary schoolchildren in Slavyansk-on-the Kuban. The research was carried out from 2005 to 2007.

We stated the following research problems:
1. Work out methods allowing teacher to control the physical fitness of 7-10 year-old children taking into account their physical growth and development.
2. Study the programs of physical education for primary schoolchildren.

We used the following methods of investigation: anthropomorphic measurements, questionnaire survey, teacher monitoring, testing of PT-instructors’ professional skills, testing of children’s physical fitness, medicobiological testing, pulse frequency measurement, educational experiment, methods of mathematical statistics.

Results and Discussion.
The physical training system for primary schoolchildren has been developed; the emphasis was put on exercise tolerance, physique-builders and physical stunts. To increase children’s endurance we recommended cyclic exercise with exercise time exceeding gradually from 1 to 10 min with pulse rate at 130-150 bpm, interval cyclic exercise performed for from 10 to 18 min varying in speed and intensity and special outdoor games.

An effective biomedical provision of physical training for schoolchildren should include the following stages: a) practical application of modern diagnostic tests for health status assessment, ancillary qualified examination of children belonging to risk-group; b) development of individual and group rehabilitation programs; c) reasoned medical group distribution of children; d) exclusion of physical exercise with injury risk from the program; e) cooperation of various experts for organizing of acute biomedical control of children’s health; f) introduction of methods allowing to estimate the results of physical education instructors’ work for improvement of children’s health and development of an incentive plan for teachers who achieved the best results in sport and recreational activities.

Conclusions
Physical education of primary school children should be altered. Poor physical growth and development of 20-40% of 7-10 year-old children disclosed during our research proves this fact.

BURNOUT AND JOB SATISFACTION LEVELS OF PHYSICAL EDUCATION TEACHERS: A GENDER DIFFERENCES
Approach
Ogul, A., Tinazci, C.
Near East University, Cyprus

For any process to succeed, is it not essential to actually it to feel happy, to like what he/she is doing and feel that it is useful? In this context the purpose of this study is to evaluate and to specify the level of the job satisfaction Level and the state of BurnOut of the physical education teachers in TRNC-Turkish Republic of Northern Cyprus.

During this study all the P.E. teachers employed in TRNC during the period of 1st of April-30th of June 2007 were targetted as test subjects.

All the data was collected by face to face contact according to “Maslach Burnout inventory” and “Minesota job satisfaction” processes. 105 questionaires were received and evaluated. Statistical technics was employed in evaluation. The difference between the female and the male subjects and the difference in length of employment were processed by t-test method. All the data was processed by using SSPS 12.0 data processing program. Error level of p<0.05 was accepted.

The findings of the study was as such: In general Burn out below an acceptable level was not found among the P.E. teachers. The female subjects was in a state of more sentimental burn out than the male P.E. teachers (p<0.05) while the male subjects and the female subjects had started their profession in a more Burned out state then the female subjects (p>0.05). In this respect the P.E. teachers’s job satisfaction level was high enough to carry on doing their job and to contribute to education. The Burn out level of the teachers was not high enough to stop them from claiming their responsibilities or avoid spending enough time for their job. Going into detail on the basis of gender, there seems to be a slight difference in Burn out level but it is not a major difference and more detailed studies within male and female groups and also on personal level can be done as a result.

EFFECT OF FATIGUE COMPLAINTS ON SALIVARY CHROMOGRAININ A LEVEL IN JUDO TRAINING AND LECTURE IN STUDENTS

Sakamoto, K., Sakamoto, N.
Hyogo College of Medicine, Japan

Effect of fatigue complaints on salivary chromogranin A level in judo training and lecture in students. Kunihiro Sakamoto, Naomasa Sakamoto Preventive Medicine, Hyogo College of Medicine, Japan

Introduction: In previous study, the effect of judo and lecture on the change rate of salivary chromogranin A (CgA) level were examined. The degree of stress of judo was 1.4 times more than that of lecture. Those who complained of yawning and sleepiness at fatigue survey showed the increased change rate of CgA. In this study the relation between salivary CgA level and complaint items of fatigue survey were analyzed.

Methods: Subjects were eight healthy male students, nonsmoker, average age 24.75 years old and standard deviation 7.94 years old. Salivary collection and fatigue survey were down three times at attend school, after first lesson and after second lesson. The fatigue survey was consisted of three categories that contained 10 complaint items in each category. Ist category was physical fatigue complaints, IInd category was psychiatric fatigue complaint and IIIth category was neurosensitive fatigue complaints.

Results and discussion: The complaint items of fatigue by judo and lecture lesson were examined using fatigue survey. Normal fatigue pattern of those three categories was a type of I>III>II in the order of the frequency of the fatigue complaint items in each category, and this pattern was 80.0% of this subjects. After Judo lesson, the complaint rate of fatigue items in lst physical fatigue category was 87.5%, and the complaint rate of fatigue items in IIIth neurosensitive fatigue category was 25.0%. After lecture lesson, the complaint rate of lst category was 87.5%, and the complaint rate of IIth category was 12.8%. Thus Judo lesson tended to show higher level of the neurosensitive fatigue than that of the lecture lesson. Salivary CgA levels were 1.141±0.873pmol/mgprotein at attend school, 1.007±1.095pmol/mg after judo and 1.058±1.209pmol/mg after lecture lesson. CgA level after judo lesson tended to decrease from the level of at attend school.

Correlation coefficients (r) between CgA level and the complaint items of fatigue were analyzed as follows, r=-0.255 for body languid, r=0.304 for yawning, r=0.309 for sleepiness, r=0.244 for feeling to lid down, r=-0.294 for heavy head and r=-0.348 for lumbago. Thus, CgA level was tend to show a positive correlation to the parasymptathic condition. The effects of the complaint items on CgA level were analyzed by multiple regression method. The standard partial regression coefficients of CgA level to the complaint items of fatigue were examined by multiple regression analyses. Those values were 0.459(p<0.02) for body languid, 0.473(p<0.02) for sleepiness, -0.447(p<0.05) for lumbago, and -0.560(p<0.03) for thirst. Thus, subjects who complained body languid and sleepiness showed high CgA level.

As a result, it seemed that salivary CgA level tended to sho

THEORETICAL DISCOURSE OF SPORT EDUCATION IN THE CONTEXT OF A HUMANISTIC PARADIGM OF EDUCATION

Chapulis, S.
Daugavpils University, Latvia

There are major changes that are taking place in our contemporary society. The changes in education has to do with the attempts of integrating humanistic and sustainable ideals in the current educational practice. The current programs of sport education in Latvia has a clear tendency towards integrating the humanistic approach in education.

In all humanistic theories a human person is seen as the highest value. All what brings benefit to a person - holistic upbringing, taking in account person’s needs, his/her health and a well being is what meters the most. Any action even if it is efficient, but not orientated towards a well being of a person- one’s self development and self-realization is viewed as anti-human, no matter whether it is a sphere of sport or any other sphere of work. Humanism allows one to reevaluate processes in education and the attitude towards a human being. Particular attention in this article is paid to the education of sport. The current article focuses on a number of question about the education as viewed through the lenses of humanistic pedagogy, as well as on fostering humanistic and spiritual values in sport education.

Missaka, M., Nascimento, R.
University State of Londrina, Brazil

Judo is a wide-known sport in Brazil, praised not only for the competitive context but also for the educative values that it implies. As well as all the society segments, sports also takes advantage of the technologic development that are of great help in the physical preparation, the clothing or the pedagogical processes. The objective of this study was to verify if children that practice Judo (white band, who had used other materials (like CD-Rom), would have better grades than the children who had used the traditional method in the examination to get the gray band. In order to do this, 12 Judo-practicing children had been selected. They were 9- and 10-year-old children, were ready for the examination for the gray band and had been trained by the same teacher. The control group consisted of children of the “Project Future” (three girls and three boys) that had participated on the conventional training of Judo. Children of the “late Club” Academy of Londrina (three girls and three boys) were the experimental group that, besides the conventional training of Judo, had also used multimedia materials. The data collection was carried out resorting to a test for theoretical evaluation, a video (practical filming) was also watched and a transcription was made to a test of practical evaluation. For the statistic analysis, the Mann-Whitney test was used to compare the averages reached by the two groups, with significance of 5%.

The results reached in the Mann-Whitney test in the evaluation of the theoretical part (p = 0.025 < 0.0) and of the practical part (p = 0.031 < 0.05) had been statistically significant for the experimental group in comparison to the control group. This leads us to infer that, in the groups studied, the reinforcement done by the multimedia materials influenced positively in the Judo-learning process.

PERFORMANCE OF BALANCE BEAM TASK OF K.T.K. BATTERY: BY PEOPLE WITH MENTAL DISABILITY

Gorla, J., Araújo, P., Oliveira, L., Lifante, S.
Universidade Estadual de Campinas -UNICAMP, Brazil

The Motor Coordination description of mentally disabled people has been scarcely studied and few references can be found about it. Evaluations are essential when choosing the Physical Education programs for people with intellectual disability. Before that, however, the
professional in this area must know how to classify the information obtained from such evaluations. To analyze the progress of individuals with intellectual disability from 6 to 11 years of chronological age of both the sexes, with mental deficiency, regarding the task of Balance on the Beam (E.Q.). The intervention used sequential practice and was carried out at APAE in Rolândia, Paraná. From a set of thirty individuals with intellectual disability, of both sexes, members of the APAE of Rolândia, Paraná, nine students were selected to be research subjects, with chronological ages from 6 to 11. The selected students were all diagnosed as having intellectual disability without syndromes and belonged to different classrooms. Only one of the subjects was female. The battery of motor coordination tests K.T.K. comprises four tasks: balance beam, hopping on one leg, jumping sideways, and shifting platforms. In this study, only the balance beam task will be analyzed. The results are described as averages (x), Standard Deviations (SD). The Wilcoxon test, a referential, non-parametrical test, allowed us to evaluate the effect of the intervention on the subjects, at a significance level of p<0.05.

Results and Discussion. - The results of this task reveal an increase of 100% in the group, that is, the initial average was 6.55 and evolved to 14.11 after the interventions. According to Table 1, these values were statistically significant at the level of p < 0.05, thus confirming the influence of the Specific Physical Education Program they went through. We should mention, however, that, when analyzed individually, according to Tables 2 and 3, children I, II, V and VII didn’t have a significant growth in the balance task, walking backwards on the beam.

Conclusion. - Given the diversity of the difficulties, it is not easy to identify with precision the measures to be taken in an Adapted Physical Education Program aimed at improving body coordination of who have mental disability, as well as which tests should be used.

Based on the achieved results, we can notice clear evidence that was done with the interventions is highly significant. However, some individuals didn’t have satisfactory results post-test, indicating a necessity of more time for the interventions and deeper analysis about other behaviors.

AN ANALYSIS OF THE VIEWS OF SECONDARY SCHOOL PHYSICAL EDUCATION TEACHERS ON CONVEYANCE OF P.E. COURSES IN SECONDARY SCHOOLS IN NORTHERN CYPRUS

Erdağ, D., Tinaczi, C.
Near East University, Cyprus

Certain factors such as the curricula followed, the level of knowledge and information possessed by instructors and their relations with the structural foundations of the institutions they work play a crucial role in educating the students undertaking physical education courses at school. This study aims at determining physical education teachers’ attitudes towards how these courses are administered in the secondary education system in Northern Cyprus. A total of 169 secondary school physical education teachers between the ages of 25-55 of whom 66 were female and 103 were male, were consulted. These participants were administered a questionnaire composed of two sections and forty-six questions. The first section includes four demographic questions where the second section consists of 42 questions designed to reveal the curricula followed by teachers, the way courses are administered and the interaction between the principal, teachers and the students. Analysis of data gathered through the surveying process is performed by the SPSS 12.0 Statistical software program. For reliability testing, the survey was administered to 10 secondary school physical education teachers twice in 5-day intervals as a pre-test. Validity and reliability of the survey is measured by Cronbach’s Alpha, which is found to be 0.91. The main finding of this article is that while physical education teachers stress the importance of P.E. courses on human development, they indicate that the school administrations and parents do not place much emphasis on these courses.

COMPARATIVE INVESTIGATION IN LOMBARDIA AMONG DIFFERENT SPORTIVE DISCIPLINES AT 11-12 YEARS

Mondoni, M., Ajani, A., Cantanna, L., Casolo, F.
Università Cattolica Sacro Cuore di Milano, Italy

This research wants to verify how much the education and the development of the motor abilities is important, respecting the individual rhythms of the motor learning and the take-offs, before improving the executive techniques of the sport. The research, made on 2006-2007, was directed to 6 different sportive disciplines, concerns 400 young males and it has interested an average of 25-55 years of age, both males and females. The participating young males trained 2-3 times at week and to school they do 2 hours of Physical Education at week, the students practice 2 hours of Physical Education in school at week and in the leisure time, they only performed no structured motor activity. The tests (administered in september 2006 at the beginning of the school and in june 2007 at the end of the school) are: Stick test and Sit & reach (flexibility), tapping and 50 m fast run (rapidity), forward throw medical-ball and long standing jump (strength of upper and lower limbs), 100 m (endurance). Some test have been administered once alone during the same session, other three times and at the last, we calculated the average.

From the result obtained by the medical screening, the tests and questionnaire, the following tendencies emerge:
- 50 mt. fast run: basketball, track and field and rugby furnish best data in comparison to the other disciplines to the control group; 1000 mt.: the control group and judo are clearly inferior in comparison to the other disciplines, Stick test: the results of handball, basketball and judo are inferior in comparison to the other sports; feel rapidly: the data of basketball, handball and judo are superior to the other sports; strength of the upper limbs: the data of basketball and handball are better than the other sports; strength of lower limbs: track and field and basketball, have the best results;
- the beginning of the sport activity is too much precocious (judo, swimming at 5-6 yr);
- the coaches works few time during training session on the development of the motor abilities compared with the time dedicated to teach technique;
- the drop-out often depends from the type of practiced sport and from the heavy trainings that too much condition the leisure time.

This research offers very interesting data on which to reflect as it regards the formulation of a correct methodology of training to propose when the boys start a new sport.

STUDENT’S RETENTION OF TEACHER’S INSTRUCTION IN PHYSICAL EDUCATION LESSONS ACCORDING TO DEMOGRAPHIC AND INFORMATION CHARACTERISTICS

Januario, N., Rosado, A., Mesquita, I.
Faculty of Human Movement of Technical University of Lisbon; Sport Faculty of Oporto University, Portugal

The present study analyzes the teacher’s instruction during Physical Education lessons, studying the coherency between the information that the teacher transmits and the one the students retain. We intended to see if the level of retention varies in relation to some students’ characteristics (gender, age and school level) and instructional characteristics (form, direction and affectivity content). Doyle (1986) suggests that the effectiveness of teaching depends on the way how students processes the information provided by the teacher. The clarity of teacher’s verbal presentations, facilitating comprehension and retention, has been considered a predictive variable in the teaching effectiveness in Physical Education. The literature about the retention of information demonstrated that quantity of information and the nature of selected instructional strategies can affect the level of retention (Cloes Knoden & Piéron, 1991, Januírio, Rosado & Mesquita, 2006). We hypothesized that not only the length or quantity of information affects the retention but, also, the nature of the information, namely, form (verbal or mixed verbal and visual), direction (personnel, group or all class) and affectivity orientation (positive versus negative). The study was developed in 35 Physical Education lessons, involving 149 students. Teacher’s instructions were audio and video recorded. After the instructional moments, the student answered to a structured interview. All teachers’ and students’ interventions were transposed to written protocol, having this information been submitted to a logic-semantic content analysis. A descriptive and comparative analysis was done. We applied the Kolmogorov-Smirnov, Mann-Whitney and Kruskal-Wallis tests. The level of significance was p < 0.05.

The results showed that the coherency between the teacher instructions and the one the student retains varied, only, according to the form of the instruction. Namely, we found a significant difference (p=0.04) when comparing the retention of verbal information (80.65% of retention) with mixed information (66.87% of retention). The direction and the affectivity content of the instructions didn’t affect the level of retention (p=0.76 and p=0.42, respectively). The value of coherency of retained information was not significantly influenced by students’ characteristics as gender (p=0.63), age (p=0.90) and school level (p=0.81).

MOTIVATIONAL TASK CHARACTERISTICS, RELEVANCE AND ACCEPTANCE OF TEACHERS INSTRUCTIONS AS PREDICTORS OF STUDENTS RETENTION OF INSTRUCTIONS

Januario, N., Rosado, A., Mesquita, I.
Faculty of Human Movement of Technical University of Lisbon; Sport Faculty of Oporto University, Portugal

The present study analyzes the teacher’s instruction during Physical Education lessons, studying the coherency between the information that the teacher transmits and the one the students retains, looking for the influence of several mediator variables. In fact, retention can be closed related to the nature of the task, namely, specific task motivation and general motivation to that particular activity or sport. Otherwise, the student’s perceptions of the relevance of the instructions being given and the agreement or acceptance of the instructions can, also, mediate retention. In order for the information to be used at a later stage, it should not be only received and comprehended but also accepted. We intended to see if instructional retention varied in relation to students’ perception of the relevance of the instructions being given and in relation to the level of acceptance or agreement with teacher’s instructions. We also related task motivation characteristics (level of task motivation and motivation for the practice of that particular sport) with retention of the instructions. The mediator paradigm emphasized the need to study student’s attention, comprehension, retention and acceptance of the instructions to really understand the learning process. It is necessary to pay attention to the retention processes, the retention is determined by attention, selection mechanisms, codification and information storage and recuperation processes that occur in interaction with particular social contexts, motor tasks and motor activities, involving not only cognitive processing but, also, affective information processing. The studies about the retention processes of teacher instructions can be decisive in the optimization of the instructional processes.

The study was developed in 35 Physical Education lessons, involved 149 students. Teacher’s instructions were audio and video recorded. Immediately after the instructional episode, the student answered a structured interview. All teachers’ and students’ interventions were transposed to written protocol, having this information been submitted to logic-semantic content analysis looking for coherency. A descriptive and comparative analysis was done. We applied the Kolmogorov-Smirnov, Mann-Whitney and Kruskal-Wallis tests. The level of significance was p < 0.05.

The results showed that the coherency between teacher instructions and the one the student retains do not vary according to the students’ perception of instruction relevance (p=0.54) and students’ level of agreement or acceptance of teacher’s instructions (p=0.43). Coherency was not, also, significantly influenced by task motivation characteristics, namely, the level of specific task motivation (p=0.55) and the general motivation to that particular sport activity (p=0.35). Our results do not confirmed that these particular variables had an impact on instructional retention in Physical Education lessons.

ARGUMENTS CONCERNING THE NECESSITY OF ELABORATION OF SOME INSTRUCTIONAL STRATEGIES SPECIFIC TO THE MINORS REEDUCATION CENTERS

Mihailescu, L., Mihailescu, N., Macri, A., Butnariu, M., Mihai, I., Cojanu, F., Valcu, B.
University of Pîlesîti, Romania

INTRODUCTION

The special educative tasks children area embraces children with difficulties, a category where we include institutionalized minors in reeducation centers, after they had committed some penal delinquencies.

CONTENT, METHODOLOGY

Our research refers to the fundamentation of advancing some educational strategies focused on objectives that are established according to the causes that have led to the delinquent act. All the methods, means and organization forms will be focused on the objectives

Thursday, July 10th, 2008
achievement and accomplishment of some competences in cognitive, moral, cultural and physic plan which can generate the reorganization of behavior in society.

The conclusions of the organizational audit offer us the possibility of elaboration educational strategy's objectives in connection to the aspects that cause delinquency and the special situation of framing on grades of the institutionalized minors: 38% of minors come from reorganized or separated families; 36% of delinquency acts represent the effect of the independence endeavor of teenagers who come from families where parents are extremely authoritative using physical compulsion and drastic punishments; 35% of minors undergo the curricular cycle of fundamental acquisitions during the liquidation of illiteracy grades at the age of 14 - 17 (13.63%; 45.4 % - 16.5 years; 38.81% - 15 years; 1.11% - 14 years);

CONCLUSIONS, DISCUSSIONS

knowing the delinquency concept and the legislative and juridical frame where the minors centers function; the operationalization of the educational and moral reeducation objects of these children; the selection of the instruction and education means according to the delinquency type and the individualization of the instruction and education routes, the promotion of some models, young people who become personalities in sport and art, as means of moral education, the selection of the instruction and education models according to the cause of committed delinquency and centering them on the individual; the simulation of self-reappraisal in connection to the society with the help of the used didactic means and methods.

SCHOOL SPORTS COMPETITION QUALITY INDICATORS IN MADEIRA

Soares, J., Antunes, H., Sumares, D.
University of Madeira, Portugal

The organisation model of school sports in the Autonomous Region of Madeira (Portugal) is important for interschool competition and represents one of the factors that attracts students and enhances the development of their sports capacities. This study aims at highlighting the quality indicators of this service with regard to sports competition of youngsters who regularly take part in school sports.

The sample consists of 1317 students enrolled in school sports (25.7%) from all schools of the 2nd and 3rd Cycles of Basic and Secondary Education of Madeira and was selected using a random stratification method applied to each nucleus/team. The data analysis and treatment procedures were then carried out using SPSS (Statistical Package for the Social Sciences) software, version 15.0 for Windows and the Microsoft Office Excel programme, version 11.0. These tools made it possible to extract results in the form of graphs and tables.

In what concerns the most practiced modalities, Footsal/Football (24.4 %) takes the clear lead in relation to the rest, followed by Volleyball (15.11%) and Basketball (12.2%). The gender distribution throughout the age groups is even and it is between the age of 12 and 13 that there is the largest number of boys and girls competing. Training began in October for 55.1% of the students but it was only after the end of November that the programme was operating at full with 92.1% of the students practicing.

One should add that training is the type of practice that gains more participation (82.5%), followed by the competitions with other schools (78.1%). However, in what concerns the number of hours dedicated to weekly training, the majority of the students (44.57%) practise only between ninety minutes and two hours. This may be explained by incompatibilities between operating hours of the sports premises and availability of students. Notwithstanding, 31% of the students practise between 12 noon and 2 pm.

One of the negative aspects of the quality of the service may be explained by the fact that students (49.4%) compete (with teams of other schools) only between one and four times during the 2006-2007 school year. The results of this study suggest that more teams be put into competition and, consequently, there be more competitions throughout the whole school year. Besides these aspects, the improvement of refereeing quality and the adequacy of transportation timetables to and from games should also be borne in mind. One should also stress that 25.4% of students enrolled in schools sports are also involved in the practice of federate sports, with football being the modality where the accumulation of the two sports types gains greater significance (40%).

PRELIMINARY RESEARCH ON PHYSICAL ABILITIES IN CHILDREN FROM 8 TO 10 YEARS IN CREMONA AND PROVINCE

Mondoni, M., Vago, P., Ajani, A., Cantanna, L., Casolo, F.
University Cattolica del Sacro Cuore of Milan, Italy

This research in 2006-2007 considered 592 children attended the 4th and the 5th class of Primary School in Cremona and province. The main goal is to know which are the factors that influence overweight and obesity as: the lack of any kind of physical activities, the presence of pararomisms, a poor diet or a wrong feeding.

This work used a questionnaire on the children's habits and style of life, a series of anthropometric and physical test. A medical visit, has been done in each school in order to measure height, weight, skinfolds, circumference of the waist, examine morphological-postural, mathematics, writing and reading tests.

The trend of the height and weight between these children is nearly equal between males (142, 5 cm ± 6, 5; 39 kg ± 6) and females (143, 5 cm ± 9, 38,5 kg ± 10,5). The body mass index has quite a similar trend between males (19 kg/m²±1) and females (18.7 kg/m²±1).

The medical visit has underlined that the majority of children does not show accentuations or meaningful reductions of the physiological curves dorsal and lumbar. In the 50 meters fast run males (8,15 s ±1,35) are faster compared to the females (.8,8 s ±1,7) but not in a significant way (p>0.0001). In the long standing test and forward throw Minibasket ball, the trend is analogous between males (143 cm ±15/46/6,5 cm ±173) and females (130 cm ±20 - 399 cm ±86). In stick test, males (88,05 cm ±7,5) obtain better results than females (96,1 cm ±91). In the Sit & rich test, females (7,3 cm ±3) obtain better results than males (7,8 cm ±4,1). In the 600 mt. test males (3,55 min ±0,42) obtain better results than females (3,91 min ±0,28).

The information from the questionnaire outlined that males (21%) spend more than an hour and half playing, instead females (20%) one hour; some child (3%) told they never play. About the sport activity practice, males prefer playing soccer, basketball and swimming instead females prefer gymnastic, swimming and volleyball. The 4% of children told they do not play any sport activities.

140

13th ANNUAL CONGRESS OF THE EUROPEAN COLLEGE OF SPORT SCIENCE
The few sport activity is associated to a bad way of eating. Only few children (3.5%) prefer eat meat, cheese and vegetables. Considering mathematics, writing and reading tests, compared to the motor tests, the results outlined children with better motor performances, are more rapid in the answers, in understanding and solving problems. Females are better compared to males.

DEVELOPMENTAL REASONS FOR SCHOOL SPORTS DROPOUT
Rosado, A., Januario, N., Mesquita, I., Martins, P.
Faculty of Human Movement, Technical University of Lisbon; Sport Faculty of Oporto University, Portugal

Voluntary sport practice in schools (school sport) is a typical sport practice environment that affects millions of students and research must address dropout reasons and the specific mediator variables that affects withdraw in this specific context. The aim of the present study was to describe students' reasons for dropout school sport practice and related them with student's developmental characteristics as gender, age and school level. The subjects were 266 students from Lisbon metropolitan area: 138 boys and 128 girls, between 12 and 21 years old. From third grade level and 100 from high (secondary) school. Data gathering was obtained through a Likert type questionnaire with 84 items, developed by Rosado & Mesquita (2003). The statistics tests used for scale evaluation were Principal Component Analysis and Cronbach Alpha. We used qui-square (with standardised residual adjusted) tests for group comparisons. We grouped influential factors into three categories: the sport-related, the milieu-related (these are the environmental factors lying outside the sport realm) and the developmental factors. Generally, the characteristics of students like age, school level and gender affect the reasons to dropout. When these variables influenced dropout, gender and school level had the most impact. With increasing age the youngster develops a desire for autonomy and begins to resent the often strictly regimented lifestyle that accompanies sport involvement and bodily changes at puberty may decrease the suitability of the physique for the sport. So, we believe that the search for dropout motives has concentrated on factors within sport at the expense of developmental and milieu-related factors. Environmental causes include physical factors (e.g., injuries), logistical factors (e.g., time constraints and organizational problems) and extra sport social-interpersonal factors (problems with others). The results showed that nonsport influences, such as work, study and family commitments are, often, stronger motives for sport disassociation than dissatisfactions with elements within the sport itself.

EVALUATION IN THE INITIAL FORMATION: REFLECTIONS AND POSSIBILITIES
Teixeira, R., Teixeira, D.
Universidade Estadual de Maringá, Brazil

This article has as objective analyze the evaluation of the process teaching learning in the initial formation, establishing as starting point, the complexity that involves the process of evaluation, its concept considering the educational scenery. For this analysis we opted for a field research and we went through some authors as (Allal et al., 1986, Bloom et al., 1988, Guba & Lincoln, 1994, Stufflebeam and Shinkfield, 1995; Madaus, Stufflebeam and Scriven, 1991; Viana, 2000) that discuss the evaluation looking for an approach with the context paradigm. This way, these constituent elements of reflections and also of relative critics to the subject of the evaluation in the teachers' initial formation, signaled the need of the development of methodologies quality evaluation that recognize the humanity of the men in the time and in the society, as well its capacity of intervention and transformation. It was possible to observe that the teachers after graduated finding difficulties in the treatment of the evaluation of the learning to be accomplished with their students in classroom, constituting in a certain discomfort. It is curious to observe that “the subject ‘evaluation’ is avoided by the teachers, even if its ‘to answer subjects, or to allow observations in classroom” (Camargo, 1999, p. 166). This discomfort can be justified for the lack of preparation in the teachers' initial formation concerning the understanding of how the knowledge is built and also how the evaluation can regulate in a quality way the process teaching-learning, answering to the teachers' expectations and students. The teachers' initial formation should assure the development of this content (evaluation) opportune to the future teacher to live forms of performance in the educational context, using different instruments of evaluation and fleeing a little to the traditional methodologies. The teacher should adapts himself to the new demands, looking for a growing qualification in the domain of the knowledge the didactic aspects, for an effective educational intervention, that approximates the pedagogic practice of democratic seeking to improve the educational practices.

BIOLOGICAL DEVELOPMENT AND BODY COMPOSITION OF TALENTED SOCCER PLAYERS
Mészáros, Z., Petrekanits, M.
mdurance Laboratory Ltd, Hungary

Education of elite athletes is a long procedure. It contains the continuous selection according to the morphological, physical, psychological etc. requirements of top athletes and specific training processes. In a practice, especially at the beginning of process, the coaches have information that arises from the responses of young athletes. The aim of the study was to evaluate the human biological consequences of trainers' selection procedure. Young athletes were selected by the evaluation of trainers based on their performance during trainings and national age group competitions. A total of 300 boys were investigated. Their calendar age ranged between 11.51 and 14.50 years. These boys represent the most talented players of Middle-Hungarian region. The athletes had preliminary 4- to 8-year training history and 5 training sessions every week. Anthropometric data collection was carried out in the summer training camp July 2007. Biological development was assessed by the morphological age (Mészáros et al., 1984). This estimate is a bone age validated age indicator. Young adult height was also predicted. Physique characteristics were described the Conrad's (1963) metric and plastic indices. Body fat content was estimated by the suggestions of Štajner (1961) and the proposals of Drinkwater and Ross (1980) were followed.
during the assessment of muscle mass relative to body weight. The young soccer players had significantly taller than average height means and moderately lighter body mass means. Their physique was definitely athletic in all age groups. Morphological age mean was significantly smaller than the calendar age in the group of 12-year-old subjects, but it was greater by 0.33 year in the oldest group. The means of body fat content relative to weight decreased with age significantly and the muscle mass showed an increasing age related trend. Taller stature of the players can be attributed to the selection procedure but the favourably low body fat content and greater muscle mass can be related to the effects of regular sports training and physique attributes. The explanation of biological age differences is not simple. We have to stress this comparison based on a cross-sectional data collection. The increasing prevalence of advanced individual may also be evaluated as selection effect. The advanced biological development has consequences both in physical and exercise physiological performance the increase of biologically older boys cannot be evaluated as a success of trainers' selection procedure.

**UNEXPECTED CARDIOVASCULAR RESPONSE DURING ULTRA-ENDURANCE EXERCISE**

Mattsson, M., Enqvist, J., Brink-Ellegård, T., Johansson, P., Bakkman, L., Ekblom, B.
Åstrand Laboratory of Work Physiology. The Swedish School of Sport and Health Sciences, Sweden

During prolonged exercise at fixed work rate heart rate (HR) increases slowly with concomitant decrease in stroke volume (SVI) in order to maintain cardiac output. Simultaneously, an increased oxygen uptake (VO2) occurs. In this paper we report an unexpected and previously not observed cardiovascular response to ultra-endurance exercise. Nine well-trained male athletes performed 24-h exercise in a controlled laboratory setting, with altering blocks of kayaking, running and cycling. Each block consisted of 110 min of exercise and 10 min of rest. Measurements (HR, VO2 and blood samples) were conducted during cycling at fixed work rate every 6th hour. The average work intensity was approximately 0.55 % of respective VO2peak. HR was increased at 6 h with 15 beats/min (13 %) compared to pre-exercise (Pre-Ex), but thereafter unexpectedly returned towards initial values. VO2 on the other hand was increased with 0.22 l/min (10 %) at 6 h and 0.37 l/min (17 %) at 12 h compared to Pre-Ex, and thereafter remained stable. This implies an increased oxygen pulse (VO2/HR) with approximately 10 % compared to Pre-Ex at the last half of the exercise. The cardiovascular drift did not progress continuously, but instead changed drastically when duration exceeded 6 hours. The changes in HR and VO2 might have different and complex explanations. HR drift might be explained mainly by central circulatory adaptation (e.g. desensitisation of cardiac adrenergic receptors) whereas drift in VO2 may depend upon peripheral changes (e.g. decreased mitochondrial efficiency). Consequently, using solely HR for determining exercise intensity and energy expenditure becomes invalid during ultra-endurance exercise, if the cardiovascular drift is not measured and taken into account.

**RECOMBINANT HUMANERYTHROPOIETIN ALTERS FLOW-INDUCED DILATATION IN SMALL MESENTERIC ARTERY OF RAT: INVOLVEMENT OF ENDOTHELIN-1**

Barhoumi, T., Berthelot, A., Laurant, P.
University of Franche-Comté, UFR STAPS, France

Chronic use of the recombinant human erythropoietin (r-HuEPO) in the therapeutic or sporting field is often accompanied by serious side effects. Being given the importance of shear stress on vasodilation induced by the rise in flow at the time of exercise, we propose to study the direct influence of r-HuEPO on the flow-induced dilatation of rat mesenteric arteries. Mesenteric arteries were cannulated, pressurized (60 mmHg) and perfused while varying intravascular flow (from 0 to 100 µl/min) in presence or not of the NO synthase inhibitor (L-NAME, 10-4M) and/or r-HuEPO (10 IU/l). Before to increase the intravascular flow, the association L-NAME/r-HuEPO caused a slight and significant decrease in lumen diameter. L-NAME completely inhibited the flow- and NO-induced vasodilation. r-HuEPO significantly attenuated the flow-dependent vasodilatation. However, the association L-NAME/r-HuEPO caused a markedly vasoconstriction in response to the rise in intravascular flow. In the presence of Bosentan (10-5M), an endothelin-1 receptor blocker, the flow-induced vasoconstriction induced by L-NAME/r-HuEPO disappeared without to restore vasodilation. Furthermore, cumulative addition of endothelin-1 induced a concentration-dependent constriction of mesenteric arteries which was significantly increased and shifted to the left in presence of L-NAME/r-HuEPO. Our results suggest that, in absence of NO, r-HuEPO induces vasoconstriction in response to the rise intravascular flow and shear stress, probably via an increased release and/or sensitivity to endothelin-1.

**AUTONOMIC NERVOUS SYSTEM RECOVERY FOLLOWING SUPRAMAXIMAL EXERCISE**

Stuckey, M., Tordi, N., Gurr, L., Rakobowchuk, M., Millar, P., Morout, L., Toth, R., MacDonald, M., Kamath, M.
McMaster University, Canada

The autonomic nervous system (ANS) is an important regulator of the cardiovascular system. ANS recovery following 2 types of supramaximal exercise (one Wingate, 4W, and four Wingates, 4W) was studied using heart rate variability (HRV). 4W consisted of 4 Wingates interspersed with 4 min. of light cycling. The RR intervals (RRi) of nine males, aged 19.4 ± 0.4 yrs. were monitored during 10 min. of supine rest and 8 min. of standing after 50 min. of supine rest. Data was collected for analysis before exercise (PRE), after 50 min. of supine rest after exercise (POST1) and 1 h. 50 min. after exercise (POST2). The frequency domain of HRV was analyzed using the Blackman-Tukey method to determine low frequency (LF), high frequency (HF) and LF:HF ratio. Supine HRV showed a main effect for time for HF (p = 0.007), LF (p < 0.001) and LF:HF (p = 0.01). HF was increased at POST1 (71.9 ± 14.6) compared to PRE (105.7 ± 8.3) and both LF and LF:HF were higher at POST1 (180.2 ± 15.4; LF:HF, 4.2 ± 1.2) than PRE (137.2 ± 12.5; LF:HF, 1.4 ± 1.2). There was a main effect for time for standing HRV such that HF was decreased (p = 0.047) at POST1 (30.9 ± 11.2) compared to PRE (41.6 ± 16.4). The type of exercise had no effect on HRV. We conclude that ANS takes longer than 1 h. to recover following supramaximal exercise. This study was supported by NSERC Canada.

**EFFECTS OF ECCENTRIC EXERCISE TRAINING ON OSTEOGENESIS AND ADIPOGENESIS IN RAT PROXIMAL TIBIAE**

Yuki, A., Yotani, K., Tamaki, H., Takakura, H.
National Institute of Fitness and Sports, Japan

Introduction: Marrow stromal cells can differentiate into osteoblasts and adipocytes. The osteoblast-adipocyte balance is influenced by local factors, especially mechanical load. We demonstrate here that the training of hindlimb muscle with high-force contractions influences osteogenesis and adipogenesis in bone.
Material and methods: Two groups of Sprague Dawley female rats (5 weeks old, n=13) were used: control (Con, n=8), high-force resistance training (Train, n=5). Training consisted of 60 stimulated eccentric contractions of the left and right ankle plantar-flexors every 2 weeks for 8 weeks. Contractions were performed under anesthesia using electrical stimulation at 140 Hz and 1.5 second and servomotor. After the training period, contractile properties in the plantar (PLA) muscles were measured, and then PLA, the right and left tibiae were obtained. After fixation with 1 % glutaraldehyde, 1 % formaldehyde and 0.05 % CaCl2 in 0.1 M sodium cacodylate buffer (pH 7.3), the right tibiae were quickly frozen in isopentane, cooled using liquid nitrogen for carboxymethyl cellulose (CMC) gel block preparation, the left tibiae were demineralized in 0.1 M disodium ethylenediaminetetraacetic acid (pH 7.3) for 6 weeks at 4 °C, dehydrated through a graded ethanol series, and embedded paraffin. The frozen tibiae were re-embedded in 5% CMC gel and frozen. Each CMC block was covered with a polyvinylidene chloride film coated with synthetic rubber cement. Serial longitudinal sections (10 micrometer) with the film were cut using a cryostat with a disposable tungsten carbide blade at -25°C. Specimens were stained with media of Oil red O and hematoxylin for counting the number and volume of adipocytes. Each paraffin block was cut into 5 micrometer sections using a microtome. Specimens were stained with media of Azan or HE (hematoxylin-eosin) for counting the volume of bone at the secondary spongiosa. Quantitative analysis of microscopic observations was performed using a digital microscope (Coalscope, Nikon), which comprised a video monitor and a personal computer with image analysis software (Image J ver. 1.38).

Results: The muscle characteristics and the contractile properties were not changed by 8 weeks of training. The training increased the number and volume of trabecular bone, and decreased the number of adipocyte significantly. The size of adipocyte in Train group tended to be lower (30%) than that of Con group.

These data suggest that the training of muscle with high-force contractions improved osteogenesis. Furthermore, the differentiation from marrow stromal cells to adipocytes and the maturity of adipocytes were inhibited by the training.

RELATIONSHIPS BETWEEN MUSCLE VOLUME OF ELBOW FLEXORS AND ELBOW FLEXION JOINT TORQUE IN YOUNG, MIDDLE-AGED AND ELDERLY INDIVIDUALS

Akagi, R., Takai, Y., Ohta, M., Kawakami, Y., Fukunaga, T.

Waseda University, Japan

Introduction

Muscle strength is closely related to its cross-sectional area in young and elderly individuals (1). This relationship would be theoretically converted to the relationship between joint torque (TQ) and muscle volume (MV) (2). In elderly individuals, however, no clear relationship between them is observed due to a decline in activation capacity (3). Thus, it is unclear whether TQ is related to MV in elderly individuals. This study aimed to clarify the dependence of TQ on MV in young, middle-aged and elderly individuals. In addition, age-related differences in TQ, MV and TQ/MV (an index of specific tension) were examined.

Methods

Subjects were divided into 20-34 yr group (31 men and 23 women), 50-64 yr group (13 men and 20 women), and 65-79 yr group (17 men and 22 women). The MV of elbow flexors was measured using magnetic resonance imaging. The TQ was measured using a torque meter, in which each subject performed maximal voluntary contraction of isometric elbow flexion for 3 seconds at 90 deg of elbow joint angle.

Results

The TQ was significantly correlated with MV in each sex in each group. The correlation coefficient for 20-34 yr women (r = 0.924) was significantly higher than those for 50-64 yr men (r = 0.631) and women (r = 0.680) and 65-79 yr men (r = 0.573). In addition, the correlation coefficient for 20-34 yr women tend to be higher than those for 20-34 yr men (r = 0.784) and 65-79 yr women (r = 0.758). Although there was no age effect on TQ/MV, the coefficients of variance of TQ/MV for 20-34 yr men and women were higher than those for 50-64 yr and 65-79 yr men and women. The MV for 20-34 yr men was significantly higher than that for 50-64 yr men with no significant difference in TQ.

Discussion

In contrast to a prior study (3), TQ was significantly correlated with MV in each sex in each group. This result suggests that MV is a major determinant of TQ in middle-aged and elderly individuals as well as young individuals. However, the differences in the correlation coefficients among age and/or between sexes were observed. Furthermore, the interindividual variation in TQ/MV for 50-64 yr and 65-79 yr groups was greater than that for 20-34 yr group. The age-related decline in TQ that does not always accompany a decrease in MV might be a reason for these phenomena. Given that TQ is related not only to MV but also to other factors such as agonist activation and antagonist co-activation (4), the present results suggest that the relative contribution of MV and/or the latter factor to TQ are different among each age and each sex. To put it more concretely, it is likely that the effects of the latter factor on TQ are greater for middle-aged and elderly individuals.

CHANGES IN MUSCLE MECHANICAL FUNCTION WITH 2 WEEKS OF LIMB IMMOBILIZATION IN YOUNG AND OLD HEALTHY MEN

Hvid, L., Suetta, C., Christensen, U., Justesen, L., Ørtenblad, N., Kjaer, M., Aagaard, P.

University of Southern Denmark, Denmark

Introduction

Aging can have a markedly effect on the muscle mechanical function, particularly affecting the capacity for rapid muscle force exertion (Rate of Force Development – RFD) and muscle mechanical function (1,2). However, these age-related changes can be modulated by other factors, including changes in nervous system function, and especially the level of physical activity seems to be a potent factor, e.g. in relation to hospitalization or disease (3,4). Thus, our objective was to study the effect of short-term limb immobilization on changes in muscle mechanical function in healthy young and old men, with special emphasis on the initial and late phase of maximal muscle contraction.

Methods
Results

At Pre, OM had significant lower values in MVC and late phase RFD. At Post, OM decreased (p<0.01) for all parameters (MVC ~16%, early phase RFD and Impulse ~36%, late phase RFD and Impulse ~30%). In contrast, YM only demonstrated decreases (p<0.05) in MVC (~15%), late phase RFD and Impulse (~15%). The declines in early phase RFD and Impulse were significantly greater in OM compared to YM (p<0.004-0.025). Further, in OM contractile RFD decreased disproportionally more than MVC as evidenced by a greater reduction in relative RFD (p=0.012).

Discussion

The present data demonstrate that acute limb immobilization results in significant decreases in MVC, with a somewhat equal effect in YM and OM. However, the capacity for rapid force exertion was affected to a much larger extent in OM. The findings indicate a more pronounced impairment in neural function (5,6) and/or more marked reductions in mechanical tendon stiffness in OM compared to YM, although muscular adaptations could also have contributed to this qualitative change. These findings indicate a more serious functional implications in elderly, e.g. when reacting to unexpected perturbations during walking, especially when exposed to periods of immobilization or limb disuse, either due to disease or hospitalization.

METHODOLOGICAL CONSIDERATIONS FOR THE PREDICTION OF MAXIMAL OXYGEN UPTAKE FROM PERCEPTUALLY REGULATED EXERCISE

Morris, M., Lamb, K., Cotterrell, D.
University of Chester, United Kingdom

Recent work by Eston et al (2005; 2006; 2008) suggests that maximal oxygen uptake (VO2max) can be predicted accurately and reliably using a graded perceptually regulated exercise test (PRET). Although the original study (Eston et al, 2005) reported limits of agreement (LoA) between predicted and actual VO2max scores (±5.8ml/kg/min) that were interpreted favourably, the subsequent studies were less encouraging (Eston et al, 2006; 2008), yielding LoA of 11-14 ml/kg/min that were possibly influenced by methodological shortcomings and inconsistencies. With this in mind, the present study modified the protocol and documentation connected with the PRET and re-visited its validity and reliability as a means of predicting VO2max. The modifications included: (ii) the provision of modified instructions for using the rating of perceived exertion [RPE] scale in perceptual regulation mode, (ii) randomising the order of presentation of perceptually regulated RPE levels, (iii) the provision of an additional opportunity to alter the resistance during each bout, (iv) the measurement of VO2max at the end of the testing, and (v) the use of 3min bouts at each RPE level (rather than 2min).

Twenty three volunteers (27±7 yrs) completed four counter-balanced PRETs on an electromagnetically braked cycle ergometer and one maximal graded exercise test (GXT). The PRETs required participants to regulate the exercise using Borg’s 6-20 RPE scale, at levels 9,11,13,15 and 17 in a randomised manner. The PRETs consisted of 2x2 min and 2x3 min bouts conducted over a nine day period, each separated by 48hrs. Prior to each bout a standardised set of instructions was read to the participants to facilitate their understanding of the task ahead. Throughout each PRET, oxygen uptake (VO2) was recorded continuously. VO2 values for the RPE range 9-17 were extrapolated to RPE 20 using regression analysis to predict individual VO2max scores. The concordance of the predicted and actual VO2max scores and the trial-trial reliability of the predicted scores were analysed using LoA.

Validity analysis revealed non-significant (p>0.07) differences between actual (42.2±10.1 & 41.6±10.2 ml/kg/min, 3min; 41.8±10.6 & 42.0±9.9 ml/kg/min) VO2max scores and LoA of -2±10.9 and -0.6±7.9 ml/kg/min (2min) and -0.4±9.0 and 0.2±7.3 ml/kg/min (3min). Reliability analysis of predicted VO2max scores yielded LoA of -1.4±8.5 ml/kg/min (2min) and -0.2±5.9 ml/kg/min (3min). It was concluded that the modified PRET used in the current study provided estimates of VO2max that were acceptable and better than those reported in recent studies. The estimates were most accurate and reliable when the 3min bout was employed. These findings bode well for future investigations into the application of perceptually regulated exercise tests.

REPRODUCIBILITY OF PERFORMANCE GAINS TO SIMULATED LIVE HIGH/TRAIN LOW ALTITUDE

Robertson, E., Saunders, P., Pyne, D., Aughey, R., Anson, J., Gore, C.
Australian Institute of Sport, University of Canberra, Victoria University, Flinders University, Australia

Introduction

Some elite athletes undertake multiple altitude exposures within and between training years to improve sea-level performance. The published literature on the magnitude of performance changes and the underlying mechanisms following altitude training are equivocal [1]. The wide variety of published outcomes and anecdotal evidence from athletes and coaches, suggests that reproducibility and individual response to altitude exposure is a key consideration. No previous study has addressed the reproducibility of responses to altitude exposure in the same group of athletes. This study quantified the test-retest reproducibility of physiological adaptations and performance gains following two simulated Live High/Train Low (LHTL) altitude bouts.

Methods

Sixteen highly trained male and female runners (VO2max: 70.3± 6.1 ml/kg/min, mean ± SD) completed 2 x 3-wk blocks of LHTL altitude exposure or resided near sea-level in a randomised controlled design. The altitude group (n=8) spent 14 h/day in normobaric hypoxia.
(3000 m) while the control group (n=8) slept in normoxia (600 m). Both groups trained at 600 m. Laboratory (treadmill VO2max) and field (4.5 km time-trial) performance tests were completed before and after each 3-wk altitude block. Haemoglobin mass (Hbmass) was measured before, weekly and one week after each 3-wk block. Data were log-transformed prior to analysis to reduce any bias arising from non-uniformity of error. Mean effects and their 90% confidence limits (CL) were estimated via the unequal-variances t statistic computed for change scores between pre- and post-tests (2).

Results
The altitude group demonstrated reproducible improvements after each 3-wk LHTL block in Hbmass (2.7 ± 3.1% and 2.7 ± 2.6%, mean ± SD) and VO2max (2.1 ± 3.1% and 2.1 ± 5.7%). The change in Hbmass was substantially greater after the 2nd 3-wk block in the altitude group (altitude-control: 4.1%, ±2.1%, 90% CL) but not the 1st (1.3%, ±3.2%) compared with the control group. There was no substantial difference in the change in mean VO2max between the groups in the 1st (0.9%, ±3.6%) or 2nd 3-wk block (1.4%, ±4.6%). Time-trial performance showed small and variable changes after each 3-wk LHTL block in the altitude group (1.4 ± 1.7% faster and 0.7 ± 2.0% slower, mean ± SD). Similarly there were variable changes in time-trial performance in the control group (0.6 ± 2.4% slower and 0.7 ± 1.1% faster).

Conclusion
A 3-wk LHTL altitude block can induce reproducible physiological adaptations in highly trained runners, but changes in performance are more variable. Competitive performance is dependent not only on physiological adaptations, but also on many other factors including fitness, fatigue and motivation. All these factors require careful, individual management to improve performance following altitude training.

THE EFFECT OF WEARING GRADUATED COMPRESSION STOCKINGS ON RUNNING PERFORMANCE

Creasy, R., Ali, A., Edge, J.
Massey University, New Zealand

Background. Graduated compression stockings (GCS) have been worn by world champion endurance runners to enhance performance; however, minimal published research has stipulated the optimal compression required to enhance performance. Athletes wearing knee-length GCS during 10,000 m running tests achieved lower average heart rate (HR) at the same performance time (T), indicating a possible performance enhancement.

Purpose: To quantify run time and physiological and perceptual variables for runners completing 10,000-m time trials whilst wearing different compression grades of GCS.

Methods: Following an initial familiarisation run, 9 male and 3 female competitive athletes (mean ± SD; VO2max 68.7 ± 5.8 ml/kg-1/min-1, age 33 ± 10.3 years, mass 68.5 ± 6.2 kg) completed four 10,000-m time trial runs on an outdoor 400-m track wearing either control (0 mmHg; Con), low (12-15 mmHg; Lo), medium (18-21 mmHg; Med), or high (23-32 mmHg; Hi) GCS in a randomised counterbalanced order. All trials were conducted between 18:00-20:00 h and average temperature and humidity were 18°C (12-22°C) and 71% (53-94%), respectively. Based on their performance in the familiarisation trial, athletes were set off at 1-min intervals and the same order was used for all subsequent trials. Leg power was assessed pre- and post-run via counter movement jump (CMJ) using a jump mat. Blood lactate concentration (Lact) was assessed pre and post-run while HR was monitored continuously during exercise. Perceptual scales were used to assess the comfort, tightness and any pain associated with wearing GCS.

Results: There were no statistically significant differences in performance time between trials (min:s; Con 39:50 ± 4.58, Lo 39:26 ± 3.57, Med 39:41 ± 3.46, Hi 39:51 ± 4.01, P=0.99). The delta change in pre- to post-exercise CMJ performance was significantly better in Lo (1.2 ± 6.0 cm) and Med (1.7 ± 4.8 cm) than Con (-2.9 ± 3.9 cm, P=0.001). Mean HR was not different between trials (168-169 beat/min-1, P=0.99) but [La] was significantly higher in GCS trials relative to Con (P<0.001). Participants rated Con and Lo as more comfortable than Med and Hi (P<0.01), Med and Hi were rated as tighter than Lo (P<0.01) and all GCS were rated as tighter than Con (P<0.01), and Hi was associated with the most pain (P<0.01).

Conclusions: In competitive runners wearing GCS does not appear to affect 10,000 m performance time. However, low and medium grade GCS help retain leg power following exercise thus possibly having implications for sprint performance at the end of a race. Furthermore, low grade GCS appear to be the most comfortable type of garment for runners.

RELIABILITY OF AN ENDURANCE RUNNING PERFORMANCE TEST

Rollo, I., Williams, C., Nevill, A.
Loughborough University, United Kingdom

The aim of the present study was to determine the reliability of a running endurance test using an automated treadmill system which requires no manual input to control running speed. On three separate occasions, 7 days apart, ten experienced male endurance trained runners (age 32 ± 10 yrs, VO2peak 61 ± 7 ml kg-1 min-1 mean ± SD) completed a treadmill time trial, in which they were instructed to run as far as possible in 60 min. The treadmill was instrumented with an ultrasonic feedback-controlled radar modulator that spontaneously regulated treadmill belt velocity corresponding to the changing running speed of each runner. Estimated running intensity was 70 ± 11 % VO2peak and distance covered 13.5 ± 2 km, with no difference between trials. The coefficient of variation (CV), estimated using ANOVA with subject and trial as main effects, was 1.4%. In summary, using an automated treadmill system, improves the reliability of 60 min treadmill time trial compared to time trials where speed is controlled manually. The present protocol is a reliable method of assessing endurance performance in endurance trained runners.
EXERCISE TRAINING PREVENTS THE CARDIOVASCULAR RISK INDUCED BY CHRONIC KIDNEY DISEASE IN RATS TREATED WITH RECOMBINANT HUMAN ERYTHROPOIETIN

Meziri, F., Simões, M., Touati, S., Barhoumi, B., Berthelot, A., Touyz, R., Laurant, P.
1) University of Franche-Comté, UFR STAPS/SMP and 2) University of Ottawa, CANADA, France

Chronic renal failure (CRF) is associated with endothelial dysfunction accompanied by many pathogenetic factors which contribute to hypertension and coronary artery disease, major causes of morbidity and mortality in patients with renal failure. Recombinant human erythropoietin (rHuEPO) has been widely used for long-term treatment of anemia that is associated with chronic renal failure. It is however recognized that rHuEPO can be responsible of arterial hypertension (HTA). It has been reported that exercise may influence the progression of chronic renal disease in both man and animals. Exercise training, which has some potential for improving cardiovascular and metabolic disorders, is beneficial in the treatment of many chronic disease states including hypertension. On these bases, we investigated whether physical activity in CRF rats treated with rHuEPO, prevents the associated cardiovascular risk.

Rats with 5/6 renal mass ablation were submitted to treadmill exercise for 30/60 min (5 times/week for 7 weeks). During the same period, Rats were treated or not with rHuEPO (100 UI/kg, twice a week, subcutaneous injection). The blood pressure was measured weekly. After sacrifice of rats, the citrate synthase activity was measured at the soleus muscle. Hematocrit, serum creatinine, and blood urea were measured. The vasorelaxation of the aorta to acetylcholine was studied. The vasodilatory response to intravascular flow of isolated perfused and pressurized mesenteric small arteries was also investigated.

An arterial high blood pressure developed in CRF rats associated to a deterioration of the aortic endothelium- and NO-dependent vasorelaxation compared to Sham rats. rHuEPO did not accentuate hypertension in CRF rats. Exercise, associated or not to rHuEPO treatment, prevented blood pressure elevation and endothelial dysfunction in CRF rats. Anemia did not appear in CRF rats but hematocrit increased in rats treated with rHuEPO. Endothelium- and NO-dependent vasodilation of perfused mesenteric arteries in response to increased intravascular flow levels was altered in CRF rats and more severely in rHuEPO compared to Sham rats. This deterioration was prevented in all rats submitted to exercise training.

In conclusion, exercise prevents hypertension and endothelial dysfunction induced by CRF and/or rHuEPO in rats. These findings indicate that exercise may be preventive upon cardiovascular risk associated with chronic kidney disease and rHuEPO treatment.

INTERRELATION OF PSYCHO-PHYSIOLOGICAL FACTORS AND PARAMETERS OF MOTOR-EVOKED POTENTIAL OF THE UPPER AND LOWER LIMB MUSCLES AT MOTOR CORTEX MAGNETIC STIMULATION

Ivanov, S.
Velikiye Luki State Academy of Physical Education and Sports, Russia

Management of movements is defined by condition and peculiarities of the numerous structures of the central nervous system (CNS). Formation of motor response to stimulation is a part of complicated process, so the motor response formation are defined by both physiological and psycho-physiological characteristics of the CNS.

Peculiarities of the interrelation of physiological and psycho-physiological factors are studied in the present research. 12 athletes, aged 20-25, took part in the research. There were registered such parameters as the motor-evoked potential (MEP) threshold and a maximal MEP amplitude, motor reaction latency (MRL) at simple and selective reactions, mobility of the neural processes.

Investigation of the psycho-physiological factors was made in conditions of performing testing tasks by upper and lower extremities. The received data were processed by a correlation analysis method. During the analysis of the data, the following was revealed: correlation of MRL and MEP amplitude in case of the simple reaction is weak (r=-0.20), however, in case of the selective reaction the value is at an average level (r=-0.53). The correlation between the MRL and the MEP threshold in case of the simple reaction is lower than average (r = 0.31) and in case of the selective reaction it is higher than average (r=0.62).

The correlation of the results of the tapping test (mobility of the neural processes) and the values of the MEP amplitude is weak (r=0.15) while the correlation with the MEP threshold is lower than average (r=-0.31). Thus, to a definite extent, the shorter the MRL is, the higher the MEP amplitude is and the lower the MEP threshold is. The higher mobility of the neural processes is, the lower the MEP threshold is and higher the MEP amplitude is.

The revealed peculiarities of the correlation between parameters of the MEP of the upper limb muscles and psycho-physiological characteristics thus confirm the previous results of the registered MEP of the upper limb muscles. The parameters of the MEP of the upper limb muscles are in stronger correlation with the psycho-physiological characteristics received at upper limb testing than those received at lower limb testing. In its turn, the parameters of the MEP received from the lower limb muscles are in stronger correlation with the results of the psycho-physiological testing, in conditions of lower limb testing. Such results are likely to be conditioned by formation of the upper and lower limb muscles MEP in different areas of the motor cortex.

Thus, on the ground of the foresaid, we can conclude that the mechanisms of formation of the upper and lower limb muscles MEP have a similar structure.

DOES OXIDATIVE CAPACITY AFFECT ENERGY COST? AN IN VIVO MR INVESTIGATION OF SKELETAL MUSCLE ENERGETICS

Layec, G., Bringard, A., Vilmen, C., Micallef, JP., Le Fur, Y., Perrey, S., Cozzone, PJ., Bendahan, D.
Centre de Résonance Magnétique Biologique et Médicale (CRMBM), UMR CNRS 6612, France

Although it is commonly accepted that training improves muscle oxidative capacity, investigations of training effects on exercise energy cost through cross-sectional studies have yielded conflicting results (Gissane et al., 1991; Mallory et al., 2002, Johansen & Quistorff, 2003, Mogensen et al., 2006). In addition, muscles investigated and exercise mode differed from those mainly involved in the training process and the energy cost has been assessed through whole body measurements thereby questioning the conclusions related to the local metabolic adaptations induced by exercise training. The purpose of the present study was to compare quadriiceps energy cost and oxidative capacity between endurance-trained and sedentary subjects during heavy dynamic knee extension.

We quantified the rates of ATP turnover from oxidative and anaerobic pathways with 31P MRS and we measured simultaneously pulmonary oxygen uptake in order to assess both muscle and O2 energy cost. Seven sedentary (SED) and seven endurance trained (TRA) male subjects performed dynamic standardized rest-exercise-recovery protocols at an exercise intensity corresponding to 35% of maximal voluntary contraction. Changes in muscle recruitment occurring within the quadriiceps were measured using surface electromyography.
Endurance trained subjects exhibited a higher maximal pulmonary oxygen uptake (66.1 ± 10.4 for TRA and 42.3 ± 6.2 for SED ml O2.min-1.kg-1, P < 0.01) and a larger muscle oxidative capacity (Qmax = 52.3 ± 31.4 for TRA and 25.8 ± 3.8 mM.min-1 for SED, P < 0.05). We found that the energy cost was 73 % higher in the endurance trained group (P < 0.05). This higher energy cost was mainly due to a 82 % higher oxidative ATP production although O2 cost was not significantly altered. In addition, the energy cost was related to both muscle oxidative capacity and maximal whole-body rate of aerobic energy expenditure. Overall, we found that the energy cost was increased as a result of training thereby suggesting an increased activity of additional ATP consuming processes not involved in work production e.g. ionic pumps.

EFFECTS OF MUSCLE POTENTIATION INDUCED BY PRIOR HEAVY KNEE-EXTENSION EXERCISE ON ATP PRODUCTION AND ENERGY COST

Preliminary exercise (warm-up) is well recognized to improve subsequent exercise performance through a variety of mechanisms. Increased time to exhaustion by priming heavy exercise (Jones et al., 2003) has been related to an improved oxidative ATP supply or a reduced energy cost (Rossiter et al., 2001). However, given that the glycolytic flux has not been quantified, the corresponding conclusions are questionable. Alternatively, it has been suggested that muscle potentiation could increase force output of slow twitch fibers or reduced the number of motor units recruited for a given power output so that endurance performance could be improved (Sale, 2002).

Accordingly, the purpose of the present study was to determine whether a prior heavy knee-extension exercise would affect muscle energy cost, O2 cost and quadriceps EMG activity during subsequent heavy exercise. Fourteen male subjects involved in recreational to regular physical activity performed repeated bouts of high-intensity square-wave, knee-extension exercise for 6 min, inside a whole-body magnetic resonance spectroscopy (MRS) system. Rates of ATP production through exercise. Med Sci Sports Exerc 35, 2085-2092.

This slowing may have important repercussions on motor control and balance. Therefore, the aim of this study was to investigate whether the reduced rate of torque development can be partly caused by a lower rate of neural activation, quantified by motor unit discharge frequency. Five young (18-22 years) and five elderly adults (71-84 years) took part in the study. The subjects performed isometric contractions as fast as possible with the ankle dorsiflexors while sitting with the ankle at 90°. The torque and corresponding surface and intramuscular electromyograms (EMGs) from the tibialis anterior were recorded during the fast contractions. In three subjects of both groups, mechanical responses to electrical stimulation were also recorded. The peak torque, the time to peak torque and the maximal rate of torque development were measured for each fast voluntary contraction and from the mechanical response to the electrical stimulus. The rate of EMG rise during the fast voluntary contractions was quantified by computing the integral of the rectified surface EMG (integrated EMG) from its onset: (1) to the first 25 and 50 ms, (2) to the time at which the maximal rate of torque development was attained (~75 ms), and (3) to the end of the EMG burst. During the voluntary contractions, single motor unit action potentials were also recorded and identified on the basis of amplitude, duration, and waveform shape. Their discharge frequency was measured at the offset of the fast contractions for the first three interspike intervals. During the fast contractions, the maximal rate of torque development and corresponding integrated EMG were lower in older adults, by respectively 48 % (P=0.05) and 16.5 % (P=0.05). The young adults, but not the older ones, exhibited a passive association (r²= 0.33, P<0.01) between the maximal rate of torque development and the corresponding integrated EMG. These age-related changes during fast voluntary contractions were accompanied by a decline (P=0.001) in motor unit discharge frequency (19 %, 28 % and 34 % for first three interspike intervals, respectively) and in the percentage of units (45 %, P<0.05) that exhibited double discharges (doublets) at brief intervals (< 5 ms). As aging decreased the maximal rate of torque development of fast voluntary contractions to a greater extent (~10 %) than that of an electrically evoked twitch,
collectively the results indicate that the age-related decline in maximal motor unit discharge frequency limits, in addition to the slowing of muscle contractile properties, the performance of fast voluntary contractions. 

This project was supported by the European Commission (QLK6-CT-2001-00323).

INCREASED HMAX/MMAX-RATIO INDUCED BY MAGNETIC STIMULATION OF THE HUMAN SOLEUS MUSCLE

Behrens, M., Mau-Möller, A., Zschorlich, V., Bruhn, S.

University of Rostock, Germany

Introduction

It is well known, that the electric field induced by magnetic stimulation (MS) is characterized by a great depth of penetration (Barker, 1999). Therefore, it is able to stimulate deep intramuscular motor axons, which evoke muscle contraction (Machetanz et al., 1994). The purpose of the present study was to examine the effects of repetitive MS (rMS) of the m. soleus (So) on the Hmax/MMax-ratio.

Methods

24 healthy male students took part in a double blind study. Subjects were randomly assigned to a treatment group (G1: n = 13; age 24.08 ±1.98; weight 77.77 ±7.34; height 181.31 ±6.76) and a control group (G2: n = 11; age 23.00 ±1.55; weight 79.55 ±11.67; height 182.00 ±8.31). rMS was delivered using a MagProR30 stimulator and a MC-125 circular coil. The stimulation protocol included the application of symmetric biphasic pulses, a frequency of 15 Hz, 20 trains, inter train interval 2 sec, 100 bursts per train and 40% stimulator output. rMS took place once and was applied to So of G1. G2 received a placebo rMS with 0% stimulator output. H-reflex stimulation used a bipolar set up and 0.5 ms rectangular pulses. The subjects remained in the same standardized ventral position on the CYBEX NORM Testing & Rehabilitation System (Computer Sports Medicine®, Inc.) and stayed inactive during the whole experiment with the foot fixed to the device. Before and after rMS Hmax/MMax-ratios and torque (T in Nm), produced by plantar flexion of So as a result of electrical stimulation of the N. tibialis, were evaluated.

Results

After rMS Hmax/MMax was significantly enhanced in G1 (0.585 ±0.176 vs. 0.630 ±0.142; p = 0.015), whereas Hmax/MMax of G2 remained nearly unmodified (0.516 ±0.195 vs. 0.519 ±0.214). The increment of Hmax/MMax of G1 was not generated by enhancements of Hmax (3.681 ±1.914 vs. 3.637 ±1.679), but on account of a significantly decreased Mmax (6.105 ±2.095 vs. 5.644 ±1.945; p = 0.027). Furthermore, T of G1 revealed nearly no changes (10.20 ±2.67 vs. 10.13 ±2.81).

Discussion

The decline of Mmax was likely induced by muscular fatigue, although T did not indicate on that. Hmax reduction during the course of the experiment may reflect phenomena described by Crone et al. (1999). The predominant mechanisms remain unclear.

Conclusion

The used stimulation protocol led to an enhancement of Hmax/MMax-ratio, due to the reduction of Mmax.

HEAT SHOCK AND ANTIOXIDANT PROTEIN ADAPTATIONS OF HUMAN GASTROCNEMIUS MUSCLE TO SIX WEEKS OF HIGH INTENSITY INTERVAL TRAINING

Morton, J., Bartlett, J., Croft, L., MacLaren, DPM., Reilly, T., Mc Ardle, A., Drust, B.

Liverpool John Moores University, United Kingdom

Skeletal muscle adapts to the stress of acute (Morton et al., 2006) and chronic (Morton et al., in press) contractile activity via rapid changes in gene expression to yield an increased content of heat shock proteins (HSPs) and antioxidant defences. An increased muscle content of such defence networks following stress function to restore cellular homeostasis, facilitate repair from injury and protect the cell from further insults. A consistent elevation of ‘stress proteins’ during repeated bouts of exercise may therefore be a component of the cellular mechanisms by which regular exercise provides protection against exercise-induced muscle damage. Adaptations of HSPs and antioxidants following running exercise have only been studied in the vastus lateralis, despite the gastrocnemius muscle being more metabolically active in this mode of exercise (Costill et al., 1974). The purpose of this study was therefore to investigate HSP and antioxidant adaptations in the gastrocnemius following high intensity interval training.

Following ethical approval, eight recreationally active male participants performed 50 min of high intensity intermittent running exercise, four times per week for six weeks. The protocol included a 10 min warm up at a running velocity corresponding to 70% of 2max followed by five 3 min bouts at a running velocity corresponding to 90% 2max separated by 3 min active recovery periods (1.5 min at a velocity corresponding to 25% 2max followed by 1.5 min of velocity corresponding to 50% 2max). The protocol ended with a 10 min cool-down period at a velocity corresponding to 70% of 2max. Assessments of 2max, running economy at 10 km.h-1 (Re) and performance on a Yo-Yo intermittent recovery test (IR2) were performed before and after training. Resting muscle biopsies were also obtained from the lateral portion of the gastrocnemius muscle before and after the training period. Training induced significant (P<0.05) improvements in 2max (10%), RE (4%) and IR2 (16%). Training also resulted in significant increases (P<0.05) in HSP60 (22%), αB-crystallin (8.5%), MnSOD (38%) and a tendency (P=0.09) for an increase in HSP70 (20%) content of the gastrocnemius muscle. In contrast, HSP27 content showed no significant changes following training (P=0.9).

This study is the first to examine HSP and antioxidant protein adaptations of the gastrocnemius muscle to exercise. Data demonstrate that six weeks of high intensity intermittent exercise improves both aerobic and anaerobic performance indices and induces a specific up-regulation of stress protein content of skeletal muscle. The intermittent nature of the training protocol makes this training model suitable for athletes involved in high intensity intermittent sports.

THE EFFECT OF ACUTE MODERATE AEROBIC EXERCISE ON BACTERIALLY-STIMULATED NEUTROPHIL DEGRANULATION RESPONSES IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Viana, J., Smith, A., Kosmadakis, G., Clapp, E., Feehally, J., Bishop, N.

1 Loughborough University and 2 Leicester General Hospital, United Kingdom

Patients with chronic kidney disease (CKD) suffer from immune dysfunction, leading to a high incidence of infectious complications, a major cause of morbidity and mortality among these patients (Cohen et al., 1997). It has been demonstrated that acute intensive exercise exerts a temporary depression on many aspects of immune function, whereas moderate exercise exerts little influence on these measures (Gleeson et al., 2007). However, it is not clear what effect moderate intensity exercise may have in CKD patients given their already compromised immune systems, even though regular physical activity in these patients has been shown to have a positive impact upon a variety of important parameters including muscle atrophy and cardiovascular risk as well as self-esteem and quality of life (Johansen, 2007). Therefore, the aim of this study was to determine the effects of acute moderate aerobic exercise on bacterially-stimulated neutrophil degranulation responses in patients with CKD.

Eight patients (6 males and 2 females) with a mean age of 56 years (range 38-76 years), with Stage 4 CKD (n=5) or on continuous ambulatory peritoneal dialysis (n=3), walked for 30 min on a motorised treadmill at a 1% gradient and at a speed that elicited a subjective rate of perceived exertion in the range of 12-14 (somewhat hard). Venous blood samples were collected before (pre-ex), immediately after (post-ex) and 1 h after exercise (1 h post). Elastase release from unstimulated (plasma elastase) and bacterially-stimulated neutrophils was determined by ELISA. Results were analysed using a one-factor (time of measurement) repeated measures ANOVA with post-hoc Student's paired t-tests with Holm-Bonferroni adjustment applied. Values are mean (SEM).

There was no significant effect of time on numbers of circulating neutrophils (pre-ex: 3.8 (0.5) x 10^9 cells/l, post-ex: 4.2 (0.4) x 10^9 cells/l, 1 h post: 4.3 (0.4) x 10^9 cells/l, F=2.3, P=0.170). Exercise induced an increase in plasma elastase concentration (pre-ex: 38.9 (3.8) µg/l, post-ex: 53.9 (6.9) µg/l, F=5.0, P=0.068), but values returned to resting levels 1 h after exercise (pre-ex vs. 1 h post: P=0.568). Bacterially-stimulated elastase release per neutrophil did not change immediately after exercise (pre-ex: 752 (104) fg/cell vs. post-ex: 708 (108) fg/cell, P=0.568) but had increased by 1 h after exercise (pre-ex vs. 1 h post: 1102 (156) fg/cell, P=0.019). These results suggest that 1 h after an acute bout of moderate exercise the ability of neutrophils to respond to a bacterial challenge is improved in patients with CKD, suggesting improved resistance against bacterial infection.

REDUCTION IN INTRA-ABDOMINAL ADIPOSE TISSUE AFTER AN 8-WEEK PERCUTANEOUS ELECTRICAL STIMULATION PROGRAM IN YOUNG WOMEN

Requena, B., Zabala, M., Requena, F., Garcia, I., Ribas, J., Pääsuke, M.

Faculty of Sport. University of Pablo de Olavide. Spain

BACKGROUND: Excessive deposition of visceral adipose tissue is known to predispose to cardiovascular diseases. Exercise training may counteract the aberrant metabolic profile associated with abdominal obesity both directly and as a consequence of body fat loss (Buemann and Tremblay, 1996). Several studies have shown reductions in intra-abdominal adipose tissue (IAAT) after total body strength-training programs (i.e., Ibañez et al., 2005). However, none of these studies used percutaneous electrical stimulation (PES) to activate the muscles during the strength training programs proposed. Moreover, little is known about the consequences of PES application on lipid metabolism.

OBJECTIVE: To evaluate the influence of a third-weekly progressive PES strength training program, without a concomitant weight loss diet, on IAAT in young healthy women.

METHODS: Twenty one young women (aged 17±1) participated in a 8-week PES supervised training program for abdominal muscles group. Diet, habitual physical activity and body composition were measured. Abdominal fat was obtained by computed tomography. The measurements were taken 4 weeks (wk -4) before training, immediately before training (wk 0), and at the week after the end of the training program (wk 9). Abdominal muscles were electrically stimulated during 60 min/day, 3 days/week for 8 consecutive weeks, using a dual-channel battery-powered stimulator. The stimulator delivered a biphasic current of 8 Hz frequency. The current characteristics were set up as follows: on-off mode stimulus 18 s stimulation, 2 s rest, pulse width 200ms, rise and fall time 1s, and maximal stimulation amplitude 100 mA.

RESULTS: No significant variation was observed in any of the above selected parameters during the 4-week control period. During the training period diet and physical activity were not significantly modified. After the PES training visceral and subcutaneous abdominal fat decreased significantly by 17.1 % (from 174.5 ± 141.9 to 149.4 ± 26.6 cm3, P < 0.01) and by 11.2% (from 219.0 ± 45.5 to 192.6 ± 38.8 cm3, P<0.01), respectively, while no changes were observed in body mass.

CONCLUSION: Three sessions per week of PES on abdominal muscles, without a concomitant weight loss diet significantly decreased IAAT in a group of young healthy women.

CENTRAL AND PERIPHERAL FACTORS RESPONSIBLE FOR THE INCREASE IN FORCE VARIABILITY WITH MUSCLE FATIGUE

Missonard, O., Mottet, D., Perrey, S.
University Montpellier 1, France

Introduction
It has been often reported that the variability of force output increases with muscle fatigue. However, the mechanisms responsible for the increase in force variability with fatigue are poorly understood.

Two potential factors were studied: the increase in central drive to the muscle that accompanies impairment of contractile function and the variability in the twitch mechanical response of the muscle fibre.

We conducted a series of experiments in order to determine the relative contribution of the increase in central drive and of the contractile mechanisms of muscle cell in the increase in force variability observed during fatigue. The first experiment was designed to determine to which extent the increase in force variability during fatigue parallels the increase in the motor command magnitude needed to achieve a given force. The second experiment was designed to determine to which extent the increase in central drive could account for the increase in force variability with fatigue. The third experiment was designed to determine to which extent the variability in muscle cell contractile mechanisms could account for the increase in force variability. In the 3 experiments, force fluctuations were studied at low to moderate contraction levels, where the precision of force production is likely to be most functionally relevant.

Methods
Exp 1
We studied force variability when participants were asked to sustain the same force of elbow flexion pre- and post-fatigue. The force range was 7 / 53 % of maximal voluntary contraction. Surface EMG was recorded as indicator of the neural drive to the muscles.

Exp 2
In order to control the variability due to the increase in central drive, we studied force variability when participants were asked to sustain the same level of muscular activation pre- and post-fatigue. This was done by giving participants a bio-feedback on their elbow flexor EMGs. The force range was similar as experiment 1.

Exp 3
In order to investigate the contribution of peripheral factors to force variability, we studied force variability when force was evoked by muscle electrical stimulation. Various levels of force were evoked pre- and post-fatigue (range 5 / 40 % of maximal voluntary contraction).

Results and conclusion
In Exp 1, the coefficient of variation of force increased with fatigue whatever the force level. In contrast EMG increased only at moderate force levels. It is concluded that the increase in the central drive to muscles is partly responsible for the increase in force variability during fatigue. However, our results suggest the existence of alternative mechanisms of neural but not muscular origin, especially at low force levels.

POST-EXERCISE BLOOD PRESSURE RESPONSES TO CONTINUOUS VERSES INTERMITTENT EXERCISE: EFFECTS OF TIME OF DAY

Jones, H., Taylor, C., Lewis, N., George, K., Atkinson, G.
Liverpool John Moores University, United Kingdom

According to guidelines for hypertension treatment, 30-min or more of continuous or intermittent exercise is advocated to lower blood pressure (BP). Following a bout of continuous dynamic exercise, BP does fall, but research on BP following intermittent exercise is scarce with only one study involving walking being controlled for total work done (Park et al., 2006). Nevertheless, the time of day that exercise began was not controlled in this study, even though circadian variation in the BP reactivity to exercise has been established (Jones et al., 2006). Therefore, we hypothesize that the exercise-mediated BP reduction will be greatest following intermittent exercise, even when total work done is controlled, but that time of day moderates this effect.

Eight normotensive, active males, aged 29±7 years (mean±SD), body mass 75.9±6.2 kg completed two semi-supine cycling protocols on separate occasions at 08:00 and 16:00 h on differing days. Each protocol comprised of cycling at 70% peak oxygen uptake for 30-min. Protocol 1 consisted of 30-min of continuous cycling (CONT) and protocol 2 consisted of three 10-min bouts of cycling each separated by 10-min of rest (INT). Five minutes before, and 20-min after, each exercise protocol systolic, diastolic and mean arterial (MAP) blood pressure was measured continuously. Changes from pre-exercise baseline were calculated and averaged into 5-min periods.

Over the 20-min post-exercise period, MAP changed by 1/2 mm Hg following CONT exercise compared to a -7/2 mm Hg reduction following INT exercise (P=0.029). The respective post-exercise changes in systolic and diastolic pressures were -13 (4) vs -19 (5) and 2 (2) vs -4 (2) mm Hg following CONT vs INT exercise protocols. There was no significant interaction of time of day on these protocol-determined differences in post-exercise BP responses (P>0.119). There was evidence that the post-exercise reductions in systolic, diastolic and MAP were sustained for a greater time period following the INT exercise protocol (condition x post-exercise time, P<0.010). At the 20-min post-exercise time point, MAP was 1/3 mm Hg following CONT exercise compared to -9 (3) mm Hg following INT exercise. The respective 20-min post-exercise time points for systolic and diastolic BP were -13 (4) vs -21 (6) mm Hg and 3 (2) vs -5 (2) following CONT vs INT exercise.

These findings suggest that intermittent exercise causes greater acute BP lowering effects compared with a single continuous bout of equivalent work. This greater hypotension following intermittent exercise was not moderated by time of day. Therefore, we recommend that, for optimal BP lowering, a bout of exercise should be occasionally interrupted with short rest periods.

PLASMA HOMOCYSTEINE NITRIC OXIDE AND OXIDANTS LEVELS IN FEMALE VOLLEYBALL PLAYERS AND SEDANTARIES

Mert, E., Pinar, L., Gulbahar, O., Cetin, F., Koz, M.
1)Baskent University, 2)Gazi University, 3)Ankara University, Turkey

Introduction

150

13TH ANNUAL CONGRESS OF THE EUROPEAN COLLEGE OF SPORT SCIENCE
Homocysteine (Hcy) is believed to mediate its toxic effects through the formation of oxygen-derived free radicals, namely superoxide and hydrogen peroxide (1). The relationship between the plasma Hcy and physical activity remains unanswered (2). Its setting forward that regular, non intensive exercises could decrease plasma Hcy concentrations, but intensive prolonged exercise has the contrary effect (3). It has also been showed that, hyperhomocysteinemia (HHcy) both increases and suppresses nitric oxide (NO) production. Exercise training resulted in significant increases in eNOS protein content and activity (4). Increasing eNOS protein expression, and activity, exercise training may attenuate Hcy induced endothelial dysfunction. We proposed to examine if the plasma Hcy levels, plasma lipids, plasma nitric oxide, plasma oxidants and antioxidants were different in female volleyball players and sedentary girls.

Methods
Ten female volleyball players from a professional team participated in the study. Sedentary group was formed by 7 young females of the same age (mean age = 18) among medical students in Gazi University (GU). Blood lipids, homocysteine, folate, vitamin B12, glucose, insulin, nitric oxide, MDA (as oxidant) and glutation (as antioxidant) levels were assessed in GU, Faculty of Medicine Laboratories. Data were analysed with the SPSS for windows and results were expressed as mean ± standard deviation.

Results
The Hcy (14.2 ± 3.5), NO (33.2 ± 10.3), MDA (0.7 ± 0.3) levels in volleyball players were found significantly higher than the Hcy (9.4 ± 2.3), NO (22 ± 2.9), MDA (0.4 ± 0.07) levels of sedentary girls. Although the GSH level (93 ± 8.9) is higher in volleyball players comparing to seden-tary females’GSH levels (88 ± 5.1), the difference was not significant. However there were no significant differences between the levels of plasma lipids such as kolesterol, triglyserid, HDL, LDL and VLDL. Concentrations of plasma Hcy, were negatively correlated with plasma folate and plasma vitamin B12 both in volleyball players and sedentaries.

Conclusion
We found that long term exercise didn’t decrease the plasma Hcy levels, indeed it increased the plasma Hcy, NO and MDA levels. Since Volleyball has been described as an ‘interval’ sport with both anaerobic and aerobic components, these results were correlated with Rousseau results who suggested that plasma Hcy concentrations increase in highly aerobic exercise trained athletes (5).

EVALUATION OF DELAYED ONSET MUSCLE SORENESS AFTER ECCENTRIC WORK OF VARIOUS VOLUMES
Netreba, A., Popov, D., Tsvirkun, D., Vinogradova, O.
SSC RF Institute of biomedical problems RAS, Russia
Delayed onset muscle soreness (DOMS) is one of unfavorable consequences of the intense physical activity especially of eccentric exercise. However the triggers of DOMS initiation are still unclear. The purpose of our study was to reveal the intensity of DOMS and creatine phosphokinase activity (CPK activity) after acute eccentric exercise of various volumes and equal intensities. 17 subjects performed eccentric exercise using bicycle ergometer with floating seat. The intensity of exercise was 140 % of maximal oxygen consumption. The number of 30-seCONDS exercise bouts divided by 3-minutes rest periods was chosen randomly from 3 to 12 bouts for each subject. DOMS was evaluated during 14 days recovery after an acute exercise using special scale in three tests: during going down stairs; during 10 isometric contractions of different intensities (40-100 % of maximal voluntary contraction) of knee extensors; during applications of dozed press on evaluazed muscles. The peak levels of DOMS were recorded at the 2-3 day of recovery. The relationship between the level of pain sensation and volume of exercise was rather weak. On the other hand close correlation was revealed between DOMS level and physical condition. The later was evaluated in preliminary tests. The higher was physical condition the lower were DOMS and CPK levels. Noteworthy similar attenuation of unfavorable effects of eccentric exercise was revealed when exercise was performed for a second time after a week rest. Thus DOMS and blood CPK levels after eccentric exercise depend on previous physical activity of a subject.

THE WINGATE TEST: A REFERENCE IN THE SCOPE OF CHILDREN ANAEROBIC FUNCTION
Fernandes, R., Pereira, F.
Sport Science School of Rio Maior, Portugal

Introduction
The evaluation of the anaerobic functional capacity concerning children is still a challenge in what research is concerned. The Wingate test (WAnT) is a laboratorial procedure of reference in the scope of children anaerobic evaluation (1). One of the advantages of this test is that it enables its application in both legs and arms (2) and it has been widely used in children at different ages but seldom used simulta-neously. This study intends to compare the maximum of anaerobic capacity of pre-pubescent children who are trained in different sports, such as football and swimming, bearing in mind the aim of identifying an adaptable metabolic specialization.

Methods
Participants: 22 subjects, all with two years of practice: 11 football players (age: 11,27 ± 0,47; weight: 37,82 kg ± 4,14; BMI: 17,22 ± 1,84; VO2max/kg: 57,61 ml/kg/min-1 ± 7,29) and 11 swimmers (age: 11,55 ± 0,52; weight: 41,00 kg ± 5,71; BMI: 18,09 ± 1,59; VO2max/kg: 54,39 ml/kg/min-1 ± 5,67). Modified Balke maximal protocol using ergo-spirometry procedures (Cosmed® b2) was selected to physio-logical characterization of the sample. In order to quantify anaerobic performance two applications of WAnT in the cycle ergometer (Monark® 849) were made, one for the legs (10,075/kg, 7,5 % of body weight) and other with the arms (0,05/kg, 5% of body weight) following official procedures (2). Three relative parameters were assessed for both tests: Peak Power, Average Power and Power Drop. Heart rate was measured with the Polar S610. The two groups were compared and the experimental variables correlated (SPSS, ver. 13.0).

Results
There were no significant differences observed for the experimental parameters between the groups. Nor differences were found within each group between arms and legs cycling, however, when we report our study to the graphic analysis of the power rate and the heart rate, we could saw some differences between the groups during the test and on the recovery phase.

Discussion/Conclusions

Thursday, July 10th, 2008
14:15 - 15:15

EESTORI/PORTUGAL, 09-12 JULY 2008
151
When we talk about children that attend to regular practice of swimming and football, we can say that this sport promote a very slightly adaptation on physiological characteristics in children as saw in the graphic analysis, however, the level of practice it's a very important issue that we must have in consideration. So, the results suggest that there is no metabolic specialization between the practice groups. The learning effect, the active muscle groups or the application of tests in laboratory context with children will able to explain these results.

ENDURANCE PERFORMANCE AND LACTATE REMOVAL IN WELL-TRAINED RUNNERS

Boullodos, D., Tuimil, J.
University of A Coruña, Spain

Some studies have supported an association between aerobic fitness and lactate removal following high intensity exercise, whereas others have failed to confirm an association (Tomlin and Wenger 2001). Regarding this, it was hypothesised a relationship between training status, running protocol, and lactate removal in distance runners of different training background.

Twelve well-trained endurance runners (7 middle-distance runners; 5 long-distance runners) performed after the end of the competitive season the Université de Montréal Track Test (UMTT) (Léger and Boucher 1980) for determining the maximal aerobic speed (MAS) and total final time (TUMTT). More than 48 h afterwards, they performed the time limit at MAS (Tlim) (Billat et al. 1994). Final lactate levels within the first minute after the end of both protocols were determined [LA1]. Recovery lactate levels were determined after ten minutes of the end of both protocols [LA10]. The difference between LA1 and LA10 was also calculated (LADIF).

Mean LA1 after the UMTT was 11.82 ± 2.02 mMol·L-1 whereas mean LA1 after the Tlim was 12.01 ± 1.94 mMol·L-1. After recovery, mean LA10 was 9.57 ± 1.30 mMol·L-1 after the UMTT (LADIF = -2.24 ± 2.20 mMol·L-1), whereas after the Tlim was 11.08 ± 2.55 mMol·L-1 (LADIF = -0.92 ± 2.52 mMol·L-1). LA10 values between days were significantly different (p<0.05). Only LA10 of UMTT day was significantly different than LA1 (p<0.05). Matched LA1 and LA10 between days were significantly correlated (LA1: r=0.652; p=0.022; LA10: r=0.745; p=0.003). ANOVA analysis did not reveal any influence of training status or training background on lactate removal. In summary, a group of well-trained distance runners remove lactate 10 min after performing a UMTT but not after a Tlim.

THE PROTECTIVE ROLE OF THE ALPHA-ACTININ-3 PROTEIN IN PAIN DEVELOPMENT AND MUSCLE DAMAGE AFTER TRAINING

Vincent, B., Nielen, H., Ramaekers, M., Van Leemputte, M., Hespel, P., Thomis, M.
KULeuven-Faculty of kinesiology and rehabilitation sciences, Belgium

Introduction-The ACTN3 gene encodes for the alpha-actinin-3 protein, which has an important structural function in the Z-line of the sarcomere. A stop codon (R577X) in the ACTN3 gene causes a complete loss of the protein in the XX homozygotes. Association studies show an enhanced performance of the R-allele in fast dynamic muscle tasks, while the X-allele seems beneficial for longer sustained muscle contractions(1). Little is known about the effect of the ACTN3 genotype on variability in strength training responses. Clarkson et al. reported lower baseline Creatine Kinase values [marker of muscle damage] in XX carriers compared to heterozygotes. They found no association between the R577X polymorphism and baseline strength or the change in strength or blood proteins after exercise(2). In our study we wanted to evaluate the genotype-dependent response to an acute eccentric training bout. We hypothesized that RR carriers rate less pain and show lower expression of muscle damage markers compared to the XX group. Methods-Nineteen (9RR, 10XX) healthy young (18-30 yrs) male subjects participated. The training bout consisted of 20 maximal eccentric quadriceps contractions in 8 series (4/leg). Blood samples were taken before, 6h, 24h and 48h after the training session, strength was measured before (minus one week) and after 48 hours. Muscle biopsies were taken before, 1 hour and 6 hours after the training bout and will be used to study mRNA expression profiles of hypertrophic pathway genes. A visual analogue scale (VAS) was used to evaluate the pain subjects experienced after training. Creatine Kinase was measured as a marker of muscle damage. Results-We found a significant drop in strength in each group 48 hrs post exercise, although no genotype-dependent differences were found. At 24h post training a trend (p=0.10) towards significance was found in the CK values; the RR carriers show lower serum CK levels than XX carriers. The analysis of the VAS results showed a higher rate less pain and show lower expression of muscle damage markers compared to the XX group. Results-We found a significant drop in strength in each group 48 hrs post exercise, although no genotype-dependent differences were found. At 24h post training a trend (p=0.10) towards significance was found in the CK values; the RR carriers show lower serum CK levels than XX carriers. The analysis of the VAS results showed a higher rate less pain and show lower expression of muscle damage markers compared to the XX group. The ANOVA analysis did not reveal any influence of training status or training background on lactate removal. In summary, a group of well-trained distance runners remove lactate 10 min after performing a UMTT but not after a Tlim.

VASCULAR RESPONSES TO COLD WATER IMMERSION: IMPLICATIONS FOR POST EXERCISE RECOVERY

Black, M., Green, D., Milsom, J., Jones, H., Morton, J., Gregson, W.
Liverpool John Moores University, United Kingdom

Background: Cold water immersion therapy has been shown to be effective in enhancing post-exercise recovery. Benefits may arise from cold induced reductions in limb blood flow, which serve to reduce muscle damage and inflammation following strenuous exercise. However, no study to date has comprehensively investigated the influence of cold water immersion on limb blood flow responses. The present aim was therefore to investigate the influence of water immersion temperature on lower-limb conduit artery and cutaneous blood flow.

Methods: Nine healthy male subjects (25 ± 2 years) were randomised to four different water temperatures (8°C, 11°C, 15°C, and 21°C) on separate days. During each condition, subjects were placed in a semi-reclined position on a custom-designed platform, and lowered into the water to the iliac crest for a total duration of 10 min (2 x 5 min, with a 2 min time window in-between for data collection). Rectal
temperature, skin temperature and forearm and thigh skin blood flow were continuously monitored at baseline, throughout immersion and for 30 min post-immersion. Muscle temperature was recorded immediately pre-, and post-immersion and at 30 min post-immersion. Superficial femoral artery blood flow was assessed using duplex ultrasound, in conjunction with mean arterial pressure, at rest, between immersions and during the 30 min post-immersion period. All data were analysed using a two-factor (condition x time) within participants general linear model (GLM).

Results: Mean skin temperature significantly declined during immersion under all conditions with values significantly lower in 8°C and 11°C water compared to 15°C and 21°C (P < 0.0005). Muscle temperature was also reduced in all conditions compared to baseline (P < 0.0005) with the greatest decrements observed in 8°C and 11°C water 30 min post-immersion (P < 0.0005). Femoral artery conductance was significantly reduced immediately following immersion and remained lower than baseline at 10, 20 and 30 min post-immersion under all water immersion conditions (P < 0.0005). Forearm and thigh cutaneous vascular conductance were significantly reduced during immersion under all conditions relative to baseline with further decrements observed during the 30 min post immersion period (P < 0.01). Femoral and cutaneous conductance were not significantly different between temperature conditions.

Conclusions: This study demonstrates that immersing the lower limbs in water causes significant reductions in femoral and cutaneous blood flow and conductance that may have implications for recovery of the muscle following strenuous exercise. Reductions in blood flow appear to be largely independent of water temperature (range 8-21°C), skin and muscle temperatures.

THE INFLUENCE OF ACE I/D POLYMORPHISM ON HUMAN MUSCLE FUNCTION, CONTRACTILE PROPERTIES AND MUSCULARITY OF OLDER MEN

McCauley, T., Mantasa, S., Folland, J.
Loughborough University, United Kingdom

Aging is associated with a progressive decline in muscle strength and function largely due to sarcopenia. Healthy older individuals have age related deficits in muscle power that are even greater than muscle strength (1), which is of particular concern as the loss of power can decrease physical function, the ability to live independently and increase the risk of falls. ACE genotype has been shown to influence muscle strength in young white males (2) and the ACE D allele has been found to influence fibre type composition in a Japanese population (3), potentially influencing muscle function and contractile properties but this has not been investigated in older adults. The aim of this study was to conduct a thorough investigation of the influence of ACE genotype on muscle function, contractile properties and lean body mass in a UK population of older men.

Following ethical approval a range of muscle function measurements were taken from healthy non strength trained UK white males (60-70yrs) on two occasions. A conventional strength testing chair was used to measure maximal isometric knee extensor and elbow flexor strength. Maximum twitches were electrically evoked (Digitimer DS7AH, UK) in the quadriceps to assess time to peak tension (TPT) and half relaxation time (HRT). Isokinetic knee extensor peak torque was measured at two velocities (30°.s⁻¹, 240°.s⁻¹) using isokinetic dynamometry (Cybex Norm, USA). Relative strength at high velocities (240°.s⁻¹:30°.s⁻¹) was calculated. A Dual-energy X-ray Absorptiometry (DXA) scan (Lunar Prodigy Advance DXA machine, GE Lunar, Madison, WI) was used to assess lean body mass. ACE I/D genotype was determined from whole blood samples using polymerase chain reaction. A conventional strength testing chair was used to measure maximal isometric knee extensor and elbow flexor strength. Maximum twitches were electrically evoked (Digitimer DS7AH, UK) in the quadriceps to assess time to peak tension (TPT) and half relaxation time (HRT). Isokinetic knee extensor peak torque was measured at two velocities (30°.s⁻¹, 240°.s⁻¹) using isokinetic dynamometry (Cybex Norm, USA). Relative strength at high velocities (240°.s⁻¹:30°.s⁻¹) was calculated. A Dual-energy X-ray Absorptiometry (DXA) scan (Lunar Prodigy Advance DXA machine, GE Lunar, Madison, WI) was used to assess lean body mass. ACE I/D genotype was determined from whole blood samples using polymerase chain reaction. In a preliminary cohort (n = 64) ACE genotype distribution was in Hardy Weinberg Equilibrium (P = 0.20). Characteristic differences were independent of genotype (age, height, body mass, lean body mass, body mass index). Isokinetic strength at 30°.s⁻¹ was influenced by ACE genotype (ANOVA, P = 0.01) with II genotype individuals having lower strength than ID individuals (Bonferroni corrected t, P = 0.01). No other differences were found between ACE genotypes for measures of isometric strength, relative strength at high velocities, TPT or HRT.
Isokinetic strength at 30°.s⁻¹ varied according to ACE genotype in this preliminary cohort. The knee extensors have functional importance for mobility and tasks of daily living and an ACE genotype influence on strength of this muscle group may have consequences for quality of life in old age. As the cohort number increases it will be interesting if this effect is maintained.

**DYNAMICS OF CARDIAC OUTPUT, DEOXYGENATED AND COMMON HEMOGLOBIN IN WORKING MUSCLE DURING INCREMENTAL BICYCLE TEST IN SUBJECTS WITH DIFFERENT LEVELS OF AEROBIC PERFORMANCE**

Popov, D., Borovik, A., Marchenko, D., Vinogradova, O.

SSC RF Institute for Biomedical Problems, Russia

Oxygen consumption of working muscles depends on oxygen delivery and oxidative capacity of muscle. The aim of the study was to compare dynamics of cardiac output, blood filling of working muscle evaluated by common hemoglobin and deoxygenated hemoglobin (index of muscle oxygen consumption) during bicycle incremental test till exhaustion.

7 physically active young men (VO2 max 45-55 ml/min/kg) and 8 athletes (VO2 max 55-70 ml/min/kg) participated in the experiment. Incremental ramp test till exhaustion was performed on a bicycle ergometer. Cardiac output was determined by breathing mixture with soluble and insoluble gases using gas mass-spectrometer. Cardiac output was measured at 20, 40, 60, 80, 90, 95 and 100% of maximal aerobic power. Concentrations of deoxygenated and common hemoglobin were continuously evaluated in working muscle (m. vastus lateralis) by near-infrared spectroscopy. During tests pulmonary oxygen consumption was measured breath-by-breath, lactate concentration in capillary blood was determined as well.

Half of the subjects demonstrated slowing down of an increase of common hemoglobin in m. vastus lateralis at 90-100% of maximal aerobic power. In athletes who demonstrated higher level of aerobic performance deoxygenated hemoglobin increased linearly during test till exhaustion. We assume it to be related with greater muscle oxidative capacity. Physical active subjects and less trained athletes demonstrated slowing down of an increase of common hemoglobin at submaximal aerobic power. It might be connected with low oxidative capacity of muscle or with restricted of oxygen delivery to the muscle. Noteworthy we have shown previously that during incremental one-leg knee extensions (work of small muscle mass with unrestricted oxygen delivery) the common hemoglobin increased till exhaustion in all subjects (Popov et al. 2007). In the present study the athletes with highest aerobic performance show an increase of common hemoglobin (blood volume filling) in working muscle until 90-100% of maximal aerobic power during incremental bicycle test, while less trained athletes and physical active subjects were demonstrated slowing down of total hemoglobin in working muscle at 50-80% of maximal aerobic power.

Half of the subjects demonstrated slowing down of an increase of cardiac output (due to stroke volume) at 90-100% of maximal aerobic power. The dynamics of cardiac output did not demonstrate close relation with dynamics of common hemoglobin in m. vastus lateralis during incremental bicycle test. That means that oxygen delivery to working muscle at maximal aerobic power may be restricted both by cardiac output and/or by redistribution of blood from working muscles to other regions (to breathing muscles, for example).

Thus comparison of dynamics of cardiac output with common and deoxygenated hemoglobin in working muscle allows to reveal the factors restricting individual aerobic performance.

**MATRIX METALLOPROTEINASE-EXPRESSION IN HUMAN SKELETAL MUSCLE IN RESPONSE TO EXERCISE**

Rullman, E., Strömberg, A., Wågsäter, D., Norrbom, J., Rundqvist, H., Jansson, E., Gustafsson, T.

Karolinska Institute, Sweden

The current study explored the effect of exercise training on the expression and activity of Matrix metalloproteinases (MMPs) in human skeletal muscle, and if the skeletal muscle fibres contribute to exercise induced MMP-expression. Changes of the functional and morphological characteristics of the skeletal muscle occur under various conditions and in response to a wide range of stimuli both pathological and physiological. Many of these processes require a remodelling of the extracellular matrix (ECM), degradation as well as regeneration. In fact the vast majority of genes up-regulated in as disparate phenomenon as exercise training and muscular dystrophy are extracellular related.

The MMPs is diverse and large family of proteases which degrade large variety of proteins but each MMP with a reference to specific extra cellular matrix (ECM) proteins. Expression of various MMPs is found in most tissues and has been demonstrated to play essential roles during growth, development and angiogenesis. MMP-2 and MMP-9 are two MMPs with common substrate specificity. They are collagenases with a special ability to degrade collagen IV, the most prevalent ECM protein in skeletal muscle.

Eleven subjects performed one-legged exercise four times per week for five weeks. The subjects exercised one leg for 45 min with restricted blood flow (R-leg), followed by exercise with the other leg at the same absolute workload with unrestricted blood flow (UR-leg). MMP-2, MMP-14 and tissue inhibitor of MMP (TIMP-1) showed similar patterns, a robust increase in the muscle tissue after 10 days of exercise regardless of exercise condition. In addition, MMP-2 mRNA was detectable in laser-dissected myofibers and myofiber MMP-2 expression increased with exercise training. In contrast, MMP-9 mRNA increased transiently and associated to the first exercise bout and to a greater extent with exercise with restricted blood flow. The absolute number of MMP-9 transcripts were low and MMP-2 transcripts were generally 100-fold more prevalent in this material. Still, the gelatinolytic activity of MMP-9 after a single bout of exercise was comparable to that noted from MMP-2 after 10 days of exercise. Taken together the present findings support MMPs to be involved in skeletal muscle remodelling also in non-pathological conditions such as voluntary exercise in humans. The biological significance of the difference in temporal pattern of MMP-9 expression compared to MMP-2 and MMP-14, and the greater expression of MMP-9 in the exercise condition with enhanced metabolic perturbation needs to be further elucidated.
IMPACT OF ARM-CRANK EXERCISE ON FEMORAL ARTERY BLOOD FLOW AND SHEAR RATE PATTERN IN SPINAL CORD-INJURED SUBJECTS AND CONTROLS

Thijssen, D., Green, D., Steendijk, S., Hopman, M.
Liverpool John Moores University, United Kingdom

Recent evidence suggests that exercise results in a typical blood flow pattern in inactive conduit arteries, characterised by anterograde flow during systole and substantial retrograde diasstolic flow. This oscillatory pattern acutely results in endothelial release of nitric oxide (NO) and may, therefore, be linked with improved endothelial function in inactive vessel beds as a consequence of exercise training. Purpose. To assess the role of the sympathetic nervous system in the pattern of oscillatory blood flow, we compared changes in femoral artery blood flow and shear rate during arm-crank exercise in 10 healthy men (31+/−4 yrs) and 10 age-matched spinal cord-injured (SCI) subjects who lack supra-spinal sympathetic control in the legs (33+/−5 yrs).

Methods. Before, and every 5 minutes during, a 25 minute arm crank exercise bout at 50% of the individuals maximal capacity, femoral artery blood flow and peak anterograde and retrograde shear rate were assessed using echo Doppler sonography.

Results. Femoral artery baseline blood flow was significantly lower in SCI compared with able-bodied controls. Exercise resulted in a significant increase in mean femoral artery blood flow in controls (ANOVA, P<0.05), but not in SCI, while leg vascular resistance did not change during exercise is either group. Although mean shear rate was lower in SCI than in controls (P<0.05), shear rate pattern was different between groups. Peak anterograde shear rate was significantly larger in SCI than in controls, while peak retrograde shear was not different between groups. Arm-crank exercise induced a significant increase in peak retrograde, as well as anterograde, shear rate in controls. Interestingly, SCI subjects who have no supra-spinal sympathetic control, demonstrate a similar exercise-induced change in oscillatory shear rate in the non-active conduit vessel.

Conclusion. Our findings suggest, in contrast with our hypothesis, the sympathetic nervous system is not an obligatory contributor to the changes in shear rate pattern observed in inactive regions during exercise. Other mechanisms, such as local release of vasconstrictors or systemically active sympathetic hormones, may contribute to these novel observations. More importantly, since the exercise-induced oscillatory pattern is linked with NO release, arm-crank exercise may have important clinical implications to improve vascular health in the paralyzed and physically inactive leg vasculature.

EFFECTS OF THE TRAINING PERIODIZATION IN SWIMMING RATS ON AEROBIC AND ANAEROBIC PERFORMANCES

DeAraujo, G., Papoti, M., Gobatto, F., Mello, M., Gobatto, C.
Sao Paulo State University, Brazil

Many physiological parameters have been used so far to study the effects of training on aerobic or anaerobic capacities, such as growth, nutritional condition, emotional problems and others factors. Nevertheless, our hypothesis is that the training periodization in rats allows examine some physiological effects by severe control. The objective of this study was to verify the training periodization responses on aerobic and anaerobic performance in rats (Rattus norvegicus). Seventy rats were divided randomly into two groups: Control Group (CG n=30) and Training Periodization Group (TPG n=30). All experiments were preceded by 2 weeks of individual adaptation to the water. The TPG was designed to run during a period of 12 weeks and was divided into three phases: Preparation (6 wk), Specific (4.5 wk) and Taper (1.5 wk). The Lactate Minimum Test (LACm) was adapted to determine the aerobic capacity (deAraujo et al., 2007). The aerobic performances was evaluated by maximal exhaustion time (Tlim) verified during hyperlactatemia induction phase in the LACm protocol. The lactate threshold (LTh) was used as an index of the intensity of the LACm. The Tlim was measured during the hyperlactatemia induction phase of the LACm protocol. The LTh was defined as the intensity at which the lactate concentration in serum began to increase above the pre-exercise level. The aerobic performances were compared using Analysis of Variance (ANOVA) and post-hoc Newman-Keuls test (P<0.05). The anaerobic performances were compared using Friedman test and post-hoc analysis (P<0.05).

Comparing hematologic response to three weeks of intermittent hypobaric hypoxia between trained athletes and triathletes and physically active students

Cejuela, R., Villa-Vicente, G., Rodríguez-Marroyo, J., García-López, J., Mendoca, P., Avila, C.
University of Alicante and University of León, Spain

Short-term intermittent hypobaric hypoxia (IHH) protocols have been shown to elicit acclimatization and hematologic adaptations in mountaineers and physically active individuals [2,3]. IHH stimulates endogenous erythropoietin (EPO) secretion without producing the subsequent erythropoietic response of the same IHH protocol in both physical active and trained subjects, this is the objective of this study. Thirty-two subjects participated in this study. They were highly trained athletes and triathletes (T) [VO2max (mean+SD) 69.2+-2.2 mLkg-1min-1] and physically active students who did not train (NT) [VO2max (mean+SD) 58.3+-2.1 mLkg-1min-1] and who were subdivided in two control groups (C-T and C-NT, respectively) and two experimental groups (T-IHH and NT-IHH). These last ones performed IHH by simulating 4000m of altitude (GO2Altitude, Hipoxicator System, Biomedtech, Australia) during 48h (5's exposure-5's rest/day, 7 days/week over 3 weeks). The training and non-training groups were subdivided in three phases: Preparation (6 weeks), Specific (4.5 weeks) and Taper (1.5 weeks). Preparation was considered as an adaptation to altitude and Specific phase for the optimization of the training response. IHH was carried out twice a week (days 1 and 4) and the hematologic variables were determined after the 3rd day, 15 days, and 30 days. The hematologic responses were analysed using repeated measures ANOVA. Significant differences were found in the control group of physical active students (C-T) and trained athletes (C-T-IHH) after the 1st and 3rd week. However, the hematologic responses were not different between the other groups.

References:

Thursday, July 10th, 2008
performed IHH (C-T) showed a significant decrease (p<0.05) in red cells, haemoglobin and haematocrit. We also observed a little decrease in EPO values by 19.3%. Nevertheless, red cells, haemoglobin and EPO increased when the trained athletes and triathletes performed IHH (T+IHH). EPO values were higher than those obtained in C-T, because after 3 wk they increased by 15.9% in T+IHH. Abellan et al. (2005) obtained an EPO's increase of 8.2% in highly trained athletes. The effects of IHH in non-trained physical students (NT+IHH) and trained athletes and triathletes (T+IHH) were similar in red cells (increases of 0.12 and 0.08 millions/ul, respectively), haemoglobin increase (increases of 0.1 and 0.15 g/dl, respectively) and EPO increases of 1.03 and 1.68 mL/mL, respectively. These results were different than those obtained by IHH, so future studies should elucidate this controversy. Possibly the IHH supposed an additional stimulus which increased EPO in T+IHH, and allowed to maintain hematological variables when comparing to C-T. Conclusion first, the IHH was a good stimulus for the production of erythropoietin and the derived haematological variables. Second, this stimulus was independent of the level of physical activity, and future studies should confirm this observation.

**MCT1 AND MCT4 GENE EXPRESSIONS IN ACTIVES AND LESS-ACTIVE TISSUES IN RATS SUBMITTED TO A SINGLE SWIMMING SESSION AT THE MAXIMAL LACTATE STEADY STATE**

Verlengia, R., Teixeira, L., Araujo, G., Gabotto, F., Carneiro, L., Papoti, M., Gabotto, C., Cavagneri, C.

*University of Methodist of Piracicaba and Sao Paulo State University, Brazil*

It is known that the efficient control of the lactate release to blood by active muscular fibers should play an important role in the muscular resistance to the fatigue. In those and in other tissues, the transport system is mediated by carriers denominated monocarboxylate transporters (MCT), with several isoforms. The presence and activity of the muscular MCTs, as well as in other tissues seems to be influence by the physical training, being possible that the acute exercise can stimulate the production of more transmembrane MCTs. The major efficiency of the lactate transport could produce lactate in the blood starting from the active fibers and, on the other hand, to promote the fast removal of this substrate from blood by muscles less active or in rest. It has been reported that the intensity of the exercise is a fundamental element in the MCTs synthesis activation, but the physiological mechanisms involving these responses were not still very well established. Besides, few studies have been to evaluate these effects on controlled exercise sessions, and there are a reduced number of researches involving analysis of the gene expression of MCTs in active and less active muscular fibers, that is fundamental to understanding of the lactate production-removal during exercise. In the present study, we have examined gene expression (GE) of the monocarboxylates transporters 1 and 4 (MCT1 and MCT4) in activities and inactive tissues as well as in heart and liver of rats submitted a single session of swimming exercise at the maximal lactate steady state workload (MSSLw). Our hypothesis is that lactate concentration in MSSLw may be increase the GE of the MCT1 and MCT4 in less-active tissues due the capacity of remove lactate by these tissues. All experiments were preceded by 2 weeks of individual adaptation to the water. Twenty-Four rats were separated randomly in four groups: Control (n=6); Dead immediately after MSSLw (n=6); Dead after 5 hours MSSLw (n=6) and Dead after 10 hours MSSLw (n=6). For verify GE in active tissues, gastrocnemius (White and Red), soleus muscles, liver and heart were excisions. The biceps was considered less-active tissue. The GE was determined by polymerase chain reaction (PCR). ANOVA was used in analysis statistics with post hoc Newman-Keuls test (p<0.05). The GE in MCT1 increases significantly in the liver [39.05%] 10 hours after MSSLw. In gastrocnemius while the maximum GE was immediately after exercise [62.36%]. The soleus muscle the GE increase after immediately MSSLw [202.1%] and kept increase until 10 hours after exercise [227.35% and 230%, 5 and 10 hours after MSSLw respectively]. No changes in heart, liver, biceps and MCT4 were observed. In summary, we have show that less-active muscle not changes the GE after MSSLw exercise.

**EFFECT OF EXERCISE INTENSITY ON THE CEREBROVASCULAR RESPONSES IN INTERNAL CAROTID AND VERTEBRAL ARTERY DURING DYNAMIC EXERCISE**

Sato, K., Tomoko, S.

*Research Institute of Physical Fitness, Japan*

Purpose The effect of exercise intensity on cerebral blood flow (CBF) during dynamic exercise has not yet been fully evaluated, and there is controversy as to whether increasing mean arterial pressure (MAP), cardiac output (CO), arterial carbon dioxide tensions (PaCO2), and sympathetic activity might regulate CBF during dynamic exercise. The purpose of the present study was to elucidate effect of exercise intensity on the cerebrovascular responses in the internal carotid artery (ICA) and vertebral artery (VIA) during dynamic exercise. Method Ten young adults 11 men and 9 women, age: 22.5±2.5 years, participated in this study. The exercise was performed on the recumbent cycle ergometer. The exercise consisted of a 5-min baseline followed by levels of exercise load at 30%, 50%, and 70% of the power of the VO2peak with 5-min duration of each stage. We continuously monitored CO, MAP (Model flow method with finometer), oxygen uptake (VO2), end-tidal CO2 (PETCO2) (Breathe-by-Breathe), internal carotid artery blood flow (QICA) and vertebral artery blood flow (QVA) at rest and during exercise. CBF was measured by a high resolution color-code Doppler ultrasound system and cerebrovascular resistance index (CVRICA and CVRVA) were also calculated as MAP divided by CBF. Results MAP, CO, and PETCO2 increases significantly with increase of exercise intensity. QICA increased by 12±2% during 30%VO2peak and reached a maximum 6±3% during 50%VO2peak. However, during 70%VO2peak, increase in QICA had a level off, in contrast to a continued increase in CVRICA throughout exercise. On the other hand, QVA increase in proportion to the increase of exercise intensity (17±3, 33±4, and 40±4%) at 30, 50, and 70% VO2peak, respectively. In addition, CVRVA did not change from the resting level throughout exercise. Discussion These data suggested that during dynamic exercise the blood flow responses in VA and ICA are different. This mechanism may serve to maintain a constant cerebral blood flow in the face of a large increase in perfusion pressure. In contrast, it seems that there is a little sympathetic control of blood flow and vascular responses in peripheral branches of VA as compared with ICA, and that passively increase in cerebral blood flow in VA with increasing perfusion pressure and/or PaCO2 during graded dynamic exercise.
RESISTANCE TRAINING WITH VASCULAR OCCLUSION ENHANCES CALF MAXIMAL VASODILATOR CAPACITY

Patterson, S., Ferguson, R.
Loughborough University, United Kingdom

INTRODUCTION

Resistance training increases peripheral blood flow in young healthy subjects (Rakobowchuk et al 2005). The intensity required for these changes is typically in excess of 75% 1 repetition-maximum (1RM). Previous studies have shown that low intensity (20-50% 1RM) resistance training with concomitant vascular occlusion enhances muscle hypertrophy and strength (Takarada et al 2000), however the effect of resistance training with concomitant occlusion on the peripheral vasculature is not known. The purpose of this pilot study was to determine the effect of resistance training combined with vascular occlusion on maximal vasodilatory capacity.

METHODS

15 healthy untrained females [21 ± 2 yr, 165 ± 7 cm, 61 ± 6 kg; mean ± SD] volunteered for the study which had local ethics committee approval. Participants trained 3 days per week for 4 weeks consisting of 3 sets of dynamic calf plantar-flexion to failure separated by 1 min rest. Participants were randomly assigned to one of three training groups where both limbs were trained at either 25, 50 or 75% of 1RM, one without and the other with blood flow occlusion (110 mmHg) above the knee. Calf blood flow following reactive hyperaemia (RHI) was measured pre- and post-training using venous occlusion strain gauge plethysmography.

RESULTS

At 25% 1RM RHI increased (P<0.05) by 15% (23.7 ± 7.6 to 27.2 ± 7.0 ml/min/100ml) and 28% (24.7 ± 5.0 to 31.6 ± 7.1 ml/min/100ml) in control and occluded limb, respectively. At 50% 1RM RHI increased (P<0.05) by 16% (23.2 ± 6.8 to 26.9 ± 6.7 ml/min/100ml) and 39% (20.3 ± 7.3 to 28.3 ± 9.2 ml/min/100ml) in control and occluded limb, respectively. At 75% 1RM RHI increased (P<0.05) by 32% (18.6 ± 2.9 to 24.6 ± 5.1 ml/min/100ml) and 26% (19.0 ± 2.0 to 24.0 ± 5.1 ml/min/100ml) in control and occluded limb, respectively.

CONCLUSION

Resistance training at an intensity as low as 25% 1RM, for 4 weeks, is sufficient to increase maximal vasodilatory capacity in young healthy females. Moreover, there was a tendency for a greater increase in maximal vasodilatory capacity when training at the lower intensities was performed with vascular occlusion. This data supports the idea that low intensity strength training with vascular occlusion may be of benefit to those individuals who cannot train at high intensities.

INSULIN RESISTANCE, SOCS-3 PROTEIN EXPRESSION AND VO2MAX

1 University of Las Palmas de Gran Canaria, Spain. 2 University of Zaragoza, Spain. 3 University of Copenhagen, Denmark. 4 Childhood Hospital Materno Infantil de Las Palmas, Spain

Specific members of the suppressor of cytokine signalling (SOCS) family of proteins are thought to have a role in the insulin and leptin resistance by inhibiting insulin signalling pathways [1].

Specific members of the suppressor of cytokine signalling (SOCS) family of proteins are thought to have a role in the insulin and leptin resistance by inhibiting insulin signalling pathways [1]. Purpose. To find out if SOCS3 protein expression is up-regulated in human obese skeletal muscle compared with their lean and overweight counterparts.

Methods. Sixteen lean [fat mass < 20%, ILGI], fourteen overweight [fat mass between 20-25 %, ILGI] and ten obese [fat mass > 25%, ILGI] young males were involved in this study. All groups were comparable in age (mean ± SEM) 25.9 ± 6.5; 29 ± 6.2; 30.3 ± 7.2 yrs respectively, but not in height (177.5 ± 5.5, 176 ± 6.3 and 183.9 ± 8.2 cm for LG, IG and HG respectively; P<0.05) and body mass (70 ± 5.3, 87.5 ± 9.3 and 113.2 ± 16.1 kg for LG, IG and HG respectively; P<0.001). Muscle biopsies were taken from the middle portion of the musculus vastus lateralis. Biopsies were processed for the assessment by Western blot of STAT3 phosphorylation, SOCS3, perilipin A (as a marker of intramuscular fat infiltration) and leptin receptor s (OB-R) protein expression as described elsewhere [2].

RESULTS

Results. Muscle perilipin A content, a protein only present in the adipocytes, was similar in the three groups (0.14 ± 0.27; 0.63 ± 1.4 and 0.62, P<0.01). This SOCS3 up-regulation was not explained by STAT3 phosphorylation (0.28 ± 0.24; 0.16 ± 0.18 and 0.33, P<0.05). However, SOCS3 protein expression and HOMA were not correlated. In turn, VO2max was correlated with HOMA (r= -0.62, P<0.01). This SOCS3 up-regulation was not explained by STAT3 phosphorylation (r= 0.28, P<0.04, 0.16 ± 0.18 and 0.35 ± 0.26 A.U. for LG, IG and HG respectively, P=0.08).

Conclusion. This study shows that in obesity SOCS-3 protein expression in skeletal muscles is increased by a mechanism that does not depend on STAT3 phosphorylation. Although, SOCS3 protein could play a role in insulin resistance in humans, there was no clear correlation between insulin resistance and SOCS3 expression.

A REAPPRAISAL OF THE DESCRIPTION OF THE SLOW COMPONENT OF OXYGEN UPTAKE DURING HEAVY EXERCISE

Gimenez, P., Bussó, T.
Laboratoire de Physiologie de l’Exercice, France

The slow component of the VO2 response during transition to heavy exercise was generally considered as beginning about 2 min after the onset of exercise, rather than coincident with the primary component (Barstow and Mole 1991). It results that the kinetics could be well

References

Patterson, S., Ferguson, R.
Loughborough University, United Kingdom
described by a bi-exponential model with time delays different for the two components. We aimed to re-examine this description of the VO2 response by using a mathematical construction based on an error correction with a common delay for the fast and slow components.

The proposed model included two additive terms with a coincident time delay \( t1 \), an exponential function describing the primary component with a time delay \( t1 \), a time constant \( t2 \) and an amplitude \( G1 \) and \( G2 \) an error correction which is proportional (gain \( Gc \)) to the cumulative difference from the onset of exercise between VO2 and a target value \( T \). This construction assumed that VO2 was directed by the primary component toward a value lower than the demand \( T \) and the late rise resulted in the error correction bringing VO2 closer to the demand. This model was compared to the bi-exponential model using a time delay \( t2 \), a time constant \( t1 \) and amplitude \( G2 \) for describing the slow component. Data came from 8 healthy subjects who have performed an electronically braked cycle ergometer transition from 2-min unloaded exercise to 10-min at 30W above the power output at the ventilatory threshold. Breath-by-breath VO2 was determined from measurement of inspired and expired gas using an algorithm of correction of changes in pulmonary gas stores. After removing the first 15 s and interpolating to one value per second, breath-by-breath VO2 responses were fit by the two models by use of non-linear method minimizing the sum of the square errors.

No difference between the two models was observed for the criteria of the goodness-of-fit or from the visual inspection of the residuals. Coefficients of determination \( R2 \) were 0.895±0.088 and 0.896±0.087 respectively. The proposed model provided \( G1 \) and \( t1 \) lower than with the bi-exponential model \( 1.78±0.28 \) vs \( 2.32±0.31 \) L/min\(-1\) and \( 21.6±6.7 \) vs \( 26.8±5.9 \) s (\( P<0.001 \)) respectively. No difference was observed for \( t1 \) \( 13.6±3.4 \) vs \( 13.0±3.2 \) s respectively) . \( T \) was 3.44±0.42 L/min\(-1\) which was not statistically different than baseline\(+G1+G2\) from bi-exponential model \( 3.39±0.45 \) L/min\(-1\) with a high correlation between them \( R=0.99, P<0.001 \). \( Gc \) was 0.0033±0.0026 di-
mensionless.

In conclusion, since the two different mathematical approaches gave similar fit of the VO2 responses, it questions that the late rise of VO2 would result from a phenomenon beginning about 2 min after the onset of exercise.

**EFFECTS OF SODIUM BICARBONATE INGESTION ON PH AND LACTATE DISTRIBUTION IN RED BLOOD CELLS AND PLASMA AFTER SHORT TERM HIGH INTENSITY EXERCISE**

Wahl, P., Müller, M., Zinner, C., Heine, O., Lenzen, E., Mester, J., Bloch, W.

Institute of Training Science and Sport Informatics, 2Department of Molecular and Cellular Sport Medicine, 3German Research Centre of Elite Sport; 4Olympic Training Center Rheinland, Germany

**Introduction**

Ingestion of an alkaline solution such as sodium bicarbonate (NaHCO3-) 1 3 h before exercise results in an increase in plasma HCO3- concentration (HCO3-II) and a decrease in plasma hydrogen ion \([H+]\) at the start of exercise. An increase of extracellular NaHCO3- buffer capacity is a way to facilitate the efflux of \([H+]\) and lactate \([La]\) from the muscle cell and thereby delay the critical decrease in intracellular pH during high-intensity exercise and may therefore be important in maintaining performance.

In erythrocytes \( RBC \) \( La \) and \( H+ \) ions are transported by the monocarboxylate-transporter-1 \( MCT-1 \). \( La \) and \( H+ \) ions equilibrate according to an electrochemical equilibrium \( [\text{Donnan equilibrium}] \). Under resting conditions plasma \([La]\) is approximately twice that of RBC. Ingestions of HCO3- may change the RBC membrane potential and/or the transmembrane concentrations of HCO3-, \( Cl^- \), \( K+ \) or \( Na+ \), leading to a different equilibration under resting conditions as well as to different reactions under exercise. Therefore we inves-
tigated effects of sodium bicarbonate ingestion on \([pH]\) and \([La]\) distribution in RBC and plasma after short term high intensity exercise.

**Methods**

10 healthy male subjects participated in this study. Subjects performed a 15-18sec lasting maximal exercise in judo. Subjects were instructed to perform the test in maximal effort. 2h before exercise subjects ingested HCO3- or a placebo. Blood samples were taken pre-exercise, pre ingestion, 0min, 1min, ... 10min after exercise to determine \([La]\) in whole blood, plasma and erythrocytes and blood gas parameters \([pH], \text{HCO3-}\) after the test subjects stayed in a sedentary position on a chair to keep La elimination as low as possible.

**Results**

The \( \text{HCO3-} \) and \( \text{H+} \) in plasma were significantly increased/decreased after HCO3- ingestion at all time points compared to the placebo ingestion. The mean ratio between RBC and plasma \([La]\) under resting conditions did not differ between both conditions \( 0.49±\) 0.03 \([\text{AU}]\) \( \text{Verum}\) vs. \( 0.49±\) 0.05 \([\text{AU}]\) \( \text{Placebo}\), showing a plasma \([La]\) approximately twice as high as in RBC. The ratio between RBC and plasma \( 8 \) was significantly decreased \( 0.34±\) 0.05 \([\text{AU}]\) \( \text{Verum}\) vs. \( 0.33±\) 0.05 \([\text{AU}]\) \( \text{Placebo}\) 0min post exercise, in both situations, showing a faster relative or proportional increase in plasma \([La]\) compared to RBC \([La]\). No significant differences in the ratio were found for all time points.

**Discussion**

The decrease in ratio is the consequence of a delayed La transport across RBC membrane and the consequence of saturation of the transport systems. The fast congestion of La in plasma exceeds the transport capacity of the RBC membrane. But it should be considered, that the total driving force for the co-transport of La and \( H+ \) by \( MCT-1 \) is composed of both the La and the proton gradients. Higher extracellular \( [H+] \) normally increase La influx into RBC but in this study HCO3- did not to influence the transport of La.

**OXIDATIVE PROPERTIES OF SKELETAL MUSCLE IN MICE FED ON A HIGH-FAT DIET**

Rinnankoski, R., Silvennoinen, M., Kivelä, R., Lehti, M., Kainulainen, H.

University of Jyväskylä, Neuromuscular Research Center and LIKES Research Center for Sport and Health Sciences, Finland

The underlying mechanisms related to obesity are important to be investigated in order to attenuate the global prevalence of type 2 diabetes. It has been implicated that mitochondrial dysfunction in skeletal muscle plays a role in the development of this multifactorial disease. The number and activities of mitochondria are important in oxidative metabolism of the cell and additionally metabolic changes usually accompany fiber type change. This study was conducted in order to unravel the possible changes occurring in the skeletal mus-
cle oxidative properties during type 2 diabetes. As a model for high fat diet induced type 2 diabetes we used male C57BL/6J mice. Low fat diet groups were either sedentary \( \text{LFS} \) or voluntarily wheel running \( \text{LFR} \), similarly to high fat diet groups \( \text{HFS} \) and \( \text{HFR} \) respectively.

After 8 and 17 weeks on the experiment, insulin and glucose tolerance tests and insulin sensitivity test \( \text{HOMA} \) were performed to indicate the progression of type 2 diabetes. In addition, skeletal muscle weight and epididymal fat mass were assessed and feeding efficiency was calculated. The myosin heavy chain (MHC) isoform composition was determined with SDS-PAGE, together with the succinate dehy-
drogenase (SDH) staining from the excised heterogeneous skeletal muscle samples. During the 19 week experiment the mice had volum-
tary access to running wheels. When the cumulative running of the mice was examined, there seemed not to be a significant statistical difference between the diet groups. The feeding efficacy of HF mice was greatly higher than in LF mice, but this was normalized during the experiment. Glucose clearance during the insulin tolerance test showed that runners were significantly more insulin sensitive after 17 weeks. Succinate dehydrogenase enzyme activity is used as a marker for oxidative capacity since it correlates with the total amount of mitochondria in a cell. As could be expected, the runner groups seem to have higher SDH activity, but in addition, also the high fat diet group seem to have higher SDH activity compared to low fat diet groups. It is shown that at least physical activity induces fast-to-slow alteration of the muscle fiber composition with increasing oxidative enzyme activity. It is also reported that short-term high fat feeding promotes a more oxidative fiber type. In order to verify these results in our study, we analyzed MHC isoforms. However, these protein analysis results were somewhat contradictory to what we expected and need to be further investigated. All in all, there are indications that high fat feeding and type 2 diabetes point to morphological as well as metabolic adaptations in the skeletal muscles. We hope to confirm later the hypothesis that the muscle oxidative capacity is one possible determinant of obesity.

QUADRICEPS SPECIFIC TENSION IN YOUNG MEN IS HIGHLY VARIABLE

Erskine, R., Jones, D., Degens, H.
Manchester Metropolitan University, United Kingdom

BACKGROUND It is assumed the maximal force a muscle can generate depends on the number of sarcomeres in parallel. However, the anatomical cross-sectional area (ACSA) of a muscle explains only half of the difference in strength between people (1). The aim of the present study was to further explain the inter-individual variability in strength by quantifying, for the first time, the contribution of a number of key factors that may be related to the variance.

METHODS Fifty-five healthy, untrained men (21±3 yrs) performed maximum voluntary contractions (MVCs) during isometric, unilateral leg extension at optimum knee angle. Anagonist coactivation was estimated from electromyography activity and the level of voluntary activation was assessed with superimposed stimuli. Quadriceps ACSA at 90% femur length and patella tendon moment arm (PTMA) were measured with magnetic resonance imaging, whilst femur length, Vastus Lateralis (VL) fascicle length and pennation angle were determined with ultrasound. Physiological CSA (PCSA) was calculated from the ratio of each of the constituent muscle volumes (ACSA x femur length) to VL fascicle length (assumed to be the same for all muscles) measured at MVC. The effective PCSA of the quadriceps was calculated by multiplying the PCSA of each of the constituent muscles by the cosine of the VL pennation angle. Thirty-three participants provided a VL muscle biopsy to determine myosin heavy chain (MyHC) isoform composition. A more precise calculation of quadriceps effective PCSA was obtained in a subgroup (n=14) by measuring actual muscle volume, fascicle length and pennation angle for each of the constituent muscles. RESULTS Quadriceps ACSA (65±8 cm²) correlated significantly with MVC (235±43 Nm) in both the complete cohort (R²=0.41; p<0.001) and the subgroup (R²=0.40; p<0.001). Correcting MVC for coactivation had no significant effect on this relationship but when voluntary activation was also accounted for the relationship improved by 2% (R²=0.43; p<0.001). Further adjustments for PTMA length, fibre length and pennation angle did not improve the correlation and there was no association between quadriceps specific tension (22±5 N cm²) and the proportion of type II MyHC (75±8%). DISCUSSION Quadriceps ACSA explains 41% of the variation in isometric torque in young, untrained males. Voluntary activation accounts for an additional 2% of the variance, whereas antagonists cocontraction, moment arm length, fibre pennation angle and fibre length did not further explain the variability in strength. Thus, even taking into account an extensive number of factors that could conceivably help to explain the variation, it remains largely unexplained. This strongly suggests that other factors may underlie this variance and we suggest that differences in myofibrillar packing and lateral force transmission in particular remain possibilities to be examined.

DIFFERENCES IN PHYSIOLOGICAL RESPONSE WHEN USING ROTATING SEAT VS. STANDARD SEAT ON KAYAK ERGOMETER

Gomes, B., Santos, A., Fernandes, O., Massart, A., Fontes Ribeiro, C.
Universidade de Coimbra, Portugal

Introduction
Kayak coaches and athletes are faced with various decisions involving equipment that affect performance (Ong et al. 2005). The rotating seat (RS) is an example. It was used by a sprint medallist in Olympics 2000 and then spread to others elite athletes. The RS invention intended to increase lower limb activity and trunk rotation. In the Portuguese national sprint team 50% of the men use RS. With no research on RS performance, the aim of this study is to determine if there are physiological differences between RS and the standard seat (SS) on kayak ergometer (KE).

Methods
Ten elite male kayak paddlers, all members of the Portuguese sprint team, volunteered for the study (age 22.0 +/- 3.2yrs, height 177.1 +/- 5.8cm, mass 77.7 +/- 5.4kg). Written informed consent was obtained from each subject. All subjects were required to perform two trials, using each a type of seat (RS and SS), which were conducted in random order (7 day apart). Each trial was performed at the same time of day, and subjects were asked to maintain their normal diet. A maximal incremental test, with five steps, was conducted in each trial. The work load of the last step was calculated based on the mean power of a 4 min maximal test performed on the KE prior to the beginning of the study. In each trial it was measured and recorded oxygen uptake (VO2) (Metamax-Cortex analyser), and collected finger blood sample to determine blood lactate concentration ([La-]). All physiological testing was conducted on a calibrated KE (Dansprint). Testing took place on the beginning of the competition period. All results are presented as mean ± S.D. Differences in dependent variables between trials were analysed for statistical significance with paired samples Student’s T-test (p<0.05).

Results Discussion
To be sure that the athlete performed equal trials, using RS and SS, the mean power of the steps tests were compared. No differences were found.
VO2 was slightly higher in every step of the maximal incremental test when used the RS, being statistically different only on the 5th step (p<0.05) of the tests. With the RS the athletes add average VO2 of 57.36±4.58ml.kg⁻¹.min⁻¹ and 55.25±4.22ml.kg⁻¹.min⁻¹ when used the SS. The [La-] at the end of the 5th step of the test was significantly higher (p<0.01) with rotating seat (10.60±2.62mmol.l⁻¹) comparing to normal seat (9.76±2.53mmol.l⁻¹). The higher levels of VO2 and [La-] with RS could be explain by an increase of lower limbs activity, with more muscular mass being involved when paddling on KE. However this produced the same mean power as with SS.

Conclusion

Thursday, July 10th, 2008 14:15 - 15:15
The differences between seats, at high intensities, suggest that there is no advantage in VO2 and [La-] when paddling on a KE with RS, being the SS in terms of effort more economic. Further research is required to fully understand the influence of the use of RS on kayak performance.

COMPARISON OF ENERGY COST AND RUNNING KINEMATICS IN THE TREADMILL AND IN THE TRACK
Alves, V., Reis, V., Baldari, C., Carneiro, A., Silva, A.
University of Trás-os-Montes and Alto Douro, Villa Real, Portugal

The motorized treadmill is still the most popular kind of exercise in physiological assessment of sportsmen, mainly in competitive runners. Based on oxygen uptake measurements, it has been proposed that a 1% inclination of the treadmill reflects running in the track. However, running kinematics is also pertinent to establish the correspondence between the two kinds of exercise. The aims of the present study were: i) to compare the energy cost (EC) during submaximal (ECSUB) and supramaximal (ECSUPR) running velocities in the motorized horizontal treadmill and in a synthetic athletics track; ii) to compare running stride kinematics between the two types of exercise. The sample comprised 10 male individuals chosen randomly among University physical education students, with mean age, weight, height and % of fat respectively: 21,3±2,5 years, 72,5±6,3 kg, 1,77±0,06 m, and 12,1±3,4%. The subjects performed randomly four tests with a 48h recovery between them: a discontinuous progressive intensity submaximal test and a supramaximal all-out 600m test (both in treadmill and in the track). Mean values of the EC in the treadmill versus track were, respectively: ECSUB (0,192±0,02 and 0,187±0,01 ml.kg-1.m-1), ECSUPR (0,201±0,02 and 0,198±0,02 ml.kg-1.m-1). The previous comparisons provided no statistical significance. Significant differences were found between the two exercise conditions in the following cinematic variables: stride frequency at the supramaximal velocity (3,45±0,3 in treadmill and 3,27±0,3 x.seg-1 in track) and vertical oscillation of center of mass during the support phase during differences were found between the two exercise conditions in the following cinematic variables: stride frequency at the supramaximal velocity (3,45±0,3 in treadmill and 3,27±0,3 x.seg-1 in track) and vertical oscillation of center of mass during the support phase during supramaximal intensities (3,7±0,2 in treadmill and 3,3±0,3 cm in track). We conclude that the horizontal treadmill may be used as energy cost indicator of running in the track, though higher values are to be expected in the laboratory. However the treadmill does not seem to be a good specific method for running training because the stride pattern is modified comparatively to that observed in track.

THE EFFECT OF SODIUM BICARBONATE USE ON FATIGUE THRESHOLD DURING MAXIMUM WORK IN ELITE MEN VOLLEYBALL PLAYERS
Tarverdizadeh, B.
Islamic Azad University, Bushehr Branch, Iran

Introduction
The use of substances to buffer the production of H+ ions produced during anaerobic type exercise has received some attention for a number of years. This procedure, known as ‘bicarbonate loading’ has been shown to be effective in offsetting fatigue during maximal performance.

Materials and Methods
Nine volleyball players of elite under control (no ingestion), placebo and Alkalotic conditions with maximal performance and protocol interval (6*1 minute) on cycle ergometer to participate in this project. The two tests were held in a random, Double blind Fashion and Three test sessions were undertaken, with all sessions being at least 2 but not more that 5 days apart. The every session was under three period that blood was then drawn (5ml) from a vein in the forearm. This three measurement period was basal, pre-exercise and post-exercise.

The blood samples in the three condition were analyzed for PH, HCO3- , base excess [BE], base buffer [BB], lactate, Pco2, Po2, O2 sat , also the measurement was distance and time to exhaustion on cycle ergometer. An ANOVA with repeated measures was used to determine statistical significance on the various blood and serum parameters.

Results
The results of the blood gas analyses are shown that in the experimental trial, the PH,HCO3- , base excess [BE], base buffer [BB], lactate, Pco2, Po2, O2 sat , also the measurement was distance and time to exhaustion on cycle ergometer. An ANOVA with repeated measures was used to determine statistical significance on the various blood and serum parameters.

Discussion
It is also evident that there is no simple relationship between the degree of induced alkalosis and the enhancement of anaerobic performance. In certain situations, however, a considerable ergogenic effect may be realized. Studies that employed performance trials with a large anaerobic component, large dosages of NaHco3, or repetitive work bouts showed significant effects. In general, the greater level of metabolic acidosis achieved during the exercise, the greater the ergogenic effect. The elevation in the bicarbonate ions surrounding the muscle cell possibly facilitations the movement of H+ out of the cell and helps to maintain the sarcoplasmic PH for maximal/optimal functioning during exercise.
The present study suggests that aerobic fitness is the most important factor for achieving competitive success when considering the ranking is explained by absolute maximum oxygen uptake. No other variables were significantly correlated to national ranking.

**Methods.**
Following institutional ethical approval and the completion of parental informed consent (children giving assent) 19 elite male age = (mean ± SD) 15.44 ± 1.40 years, height = 170.55 ± 7.84 cm, body mass = 63.71 ± 6.58 kg) surfers participated in assessments of maximal oxygen uptake using a specially adapted ergometer and online gas analysis. Lower body explosive power was assessed using a standing long jump, upper body power was assessed using a medicine ball throw, agility was measured using a pop-up test, static balance was measured using a standing stork test and dynamic balance was measured using a wobble board. A correlational analysis was performed between the measured physiological variables and the numerical national ranking of the subjects using SPSS for Windows (V. 14).

**Results.**
Statistical analysis revealed that there was a significant Pearson Product moment correlation between Absolute maximum oxygen uptake and national ranking (r=0.519, P<0.05, r2=0.269) and the coefficient of determination suggests that 26.9% of the variation in national ranking is explained by absolute maximum oxygen uptake. No other variables were significantly correlated to national ranking.

**Conclusion.**
The present study suggests that aerobic fitness is the most important factor for achieving competitive success when considering the physiological profile of elite junior surfers. Further research is required to ascertain at what point of physical maturity and age blood lactate and peak power measurements become significant.

**EFFECTS OF EXERCISE TRAINING ON HEAT-INDUCED VASOCONSTRICTION AND COLD-INDUCED VASODILATION IN THE FINGERS**

Sugawara, M., Taimura, A.

*University of Plymouth, United Kingdom*

**Introduction.**
Surfing is a high intensity intermittent exercise which in recent years has experienced a rapid increase in participation rates and growing professionalism amongst competitive athletes. There has been some research of the physiological aspects of surfing performance and indices of fitness which may be related to competitive performance in adults with peak power output and the exercise intensity associated with a blood lactate concentration of 4 mmol/L being significantly correlated to ranking. However, little information is available regarding junior surfers. The effects of exercise on heat-induced vasoconstriction was examined in sixteen healthy male adult volunteers (8 trained who have daily exercise and 8 untrained). Heat-induced vasoconstriction, cold-induced vasodilation, body fat %, VO2max and daily energy and protein intake were measured. The finger blood flow was measured in water of 35°C to 43°C every 10 minutes by laser Doppler flowmetry. Cold-induced vasodilation was measured during the middle finger immersion in ice water at 0.2 °C for 30 minutes.

In the trained group, body fat % (10.2 ± 0.7 %) was significantly lower than that of the untrained group (14.3 ± 1.4 %), and the VO2max (68.3 ± 1.2 ml/kg/min) and dairy protein intake (23.1 ± 18.7 g/day) were significantly greater than those of the untrained group (55.5 ± 0.7 ml/kg/min, 100.5 ± 16.5 g/day). The initial heat-induced vasoconstriction was observed four minutes after the immersion in both groups and the second heat-induced vasodilation at 14 minutes in the trained group and at 16 minutes in the untrained group. During immersion at 38 °C to 43 °C, the increase in finger blood flow per minute was greater in the trained group and the increase in finger skin temperature per minute was smaller in the trained group. The mean skin temperature (4.88 ± 2.13 °C) in trained, 12.04 ± 2.14 °C in untrained) and resistance index (13.0 ± 1.7 in trained, 10.9 ± 1.5 in untrained) as a value of cold-induced vasodilation during ice water immersion were significantly higher in the trained group. These results suggested that arteriovenous anastomosis in the fingers are more quantitatively and/or functionally superior in the trained group. Local heat and cold tolerance in the fingers are improved simultaneously by physical training.

**EFFECT OF AEROBIC TRAINING AND DETRAINING ON NOVEL INFLAMMATORY MARKER THE PREDICTIVE OF CARDIOVASCULAR DISEASE IN WISTAR RATS**

Mogharnasi M, Gaeini A.A, Sheikholeslami Vatani D, Iran

**Methods.**
Male wistar rats (3 months old) were used. The rats were randomly divided into two groups: 1) experimental group(n=24), 2) control group (n=18, without any program training). Experimental rats participated in a aerobic training program consisting of treadmill running 3 days a week for 12 weeks. Six trained rats experienced the detraining from 8th to 12th weeks. Blood samples were collected at 24h after the first session, end of 8th week and end of 12th week. sICAM-1 levels were decreased insignificantly (p=0.112) in the first 8 weeks and also was decreased significantly (p=0.000) after 12 weeks. As expected, no adaptations were observed by detraining and the body is exposed to risks of atherogenesis damages (p=0.070) confirming a prior study (1).

**Conclusions.**
In summary, this study showed that the measurement of Cellular Adhesion Molecules (sICAM-1), is beneficial for the effective diagnosis of different environmental factors of vascular disorders. On the other hand regular aerobic training would be a helpful method in prophylaxis and reduction of atherosclerosis by lowering the viscosity of sICAM-1(1,2,4).

HEART RATE RESPONSE TO GAME-PLAY IN PROFESSIONAL BASKETBALL PLAYERS DURING PRESEASON

Reloyo, I., Vaqueria Jiménez, A., Calleja González, J.
Universidad Politecnica de Madrid, Spain

Introduction. The effectiveness of using the heart rate (HR) as an indicator of exercise intensity to monitor basketball training has been the subject of intense investigation ([1,2]). However, recent new regulations and a trend towards a more conditional game have prompted a need to revise field study procedures and demanded the increased specialization of game positions.

The purpose of this study was to measure heart rate response to game-play in professional basketball players during preseason.

Materials and Methods. Five preseason matches played by a men’s Spanish professional league team were analyzed in terms of the HR response recorded in the four game quarters.

Results. For the point guards, forwards and centers, respectively, HRmax (in beats/min) were 186±11.7, 176±8.3 and 177±7.7; and HRmean (beats/min-1) were 163±14.3, 151±10.3 and 155±9.4. While similar HRmax were observed in each quarter, significant differences were detected between the %HRmax values for the point guards versus the forwards or centers (P<0.0001 and P<0.05, respectively).

Conclusions. Our findings indicate that point guards show the highest HR and forwards the lowest. HRmax and %HRmax values were high during the first quarter and continued to increase during the game, peaking in the final quarter. On the other hand our data certificated the distribution pattern shown by the HRmax, including high values for the first quarter that increased during the game and peaked in the final 10 minutes along with the %HRmax.

NO CORRELATION BETWEEN SERUM GROWTH HORMONE RESPONSE AND HEART RATE DURING ACUTE EXERCISE

Hadjovic-Dzuvco, A., Nakas-Icindic, E., Kucukallic-Selimovic, E., Valjevac, A., Zacrigac, A., Avdagic, N.
Faculty of Medicine University Sarajevo, Bosnia and Herzegovina

The concentration of growth hormone (GH) increase during acute exercise but factors that could influence that response are not well established. During the exercise condition, the resulting higher blood pressure and heart rate (HR) support blood flow and thus growth hormone releasing hormone (GHRH) transport towards the GH producing cells in the pituitary. This might be additionally cause for the significant GH release during exercise. Some results also showed that the increase in HR during exercise was blunted in the GH deficient.

The aim of this study was to establish the possible relationship between dynamics of changes in the growth hormone concentration and heart rate during acute exercise. The study involved a group of 15 healthy males, average 21.7 years of age. They performed 30 min continuous cycling at 60% of VO2max. The growth hormone concentration and the heart rate were measured in the rest, during exercise (6., 12., 18., 24. and 30. minutes) and during recovery (15., 30. and 45. minutes). The standard immunoradiometric (IRMa) method was used to determine serum growth hormone concentration.

We found significantly higher GH values at the first measure during exercise (6 minutes) compared with the rest values (0.46vs.1.95 mU/l, p=0.013). During acute work load, serum growth hormone concentration was increasing successively. Maximal increase in growth hormone concentration was measured at the end of work load (30 min.) and was 33.69 mU/l. Decrease in serum growth hormone concentration during recovery, in the relation to the concentration at the end of exercise, was established. In spite of that, the GH values after 45 minutes of recovery were significantly higher compared with the rest values (0.46vs.6.08 mU/l, p=0.001). Heart rate was increasing successively but no correlation was established between growth hormone concentration and heart rate during exercise or in the recovery period.

THE EFFECT OF SELECTIVE MATCH OF NATIONAL TEAM TO AMOUNT OF CORTISOL AND PROFILE OF PSYCHOLOGY

Hojjat, S., Tarverdizadeh, B., Rahnama, M.
ISLAMIC AZAD UNIVERSITY OF KARAJ BRANCH, Iran

The purpose of this study was to the effect of selective match of national team of Iran, amount of cortisol and profile of psychology cadet team karate national of Iran/age:17±0.6 yrs:height 177/97±6/4cm:weight 73/4±10/24kg of 28 of karate athletes. First test of psychology and cortisol assessment apply and finally repeated previous test performed. Statistical method for survey was Pierson correlation coefficient and t test.

No significant differences (p>0.05) were found between pre (14/7±4±5/23) and post (10/23±2. 64) cortisol of competition. No significant differences were found between change of psychology characteristics pre and post win or lose karateka. There was not significant correlation between cortisol with pre and post test of psychology. This data showed that competition cause increase cortisol and also decrease negative alternative for instance: angry tension deoression and fatigue.

Key words: cortisol, profile of psychology, cadet team karate national, selective match
We conclude that there is no relation between the mechanism of growth hormone and heart rate increase during acute exercise.

THE EFFECT OF 2 MONTH REGULAR AEROBIC TRAINING ON STUDENTS` REST TIME SERUM CALCIUM, PHOSPHORUS AND MAGNESIUM VARIATIONS

Pourvaghar, M.
University of Kashan, Iran

Several reports have shown that duration and/ or intensity of exercise elicit different effects on minerals metabolism and that inadequate status of the body mineral composition can lead to a diminution of performance and endurance both in sportsmen and rats. Magnesium plays an important role in calcium and bone metabolism. Magnesium deficiency alters calcium metabolism, resulting in hypocalcemia, vitamin D abnormalities and neuromuscular hyper excitability (8). On the other hand exercise may increase calcium losses. Phosphorus is also another mineral that is regulated in part by an overflow mechanism (6). When serum levels of phosphorus are high, the kidney typically excretes extra phosphorus (6). Eighty-Five percent of the body’s phosphorus is found in bone, where it binds with calcium to form the mineral hydroxypatite, which confers strength and rigidity to bones.

The purpose of this research has been the investigation of student athletes’ rest time serum calcium (Ca), Phosphorus (P) and magnesium (Mg) variations. Following this purpose, 14 students were selected to take part in this research project. The means and standard deviations of their height, weight, age and body mass index (BMI) were respectively: (175±5.9), (68.27±9.89), (20.07±1.44), (22.11±2.47). Participants trained with incremental continuous running program for 16 sessions with certain and pre-adjusted heart rate intensity and distance. Heart rate intensity was controlled by polar clock. Blood samples were taken from subjects in pre- and post- test in rest condition. Test of running - jugging was performed for determining maximum oxygen consumption (Vo2 max). The analysis of data by SPSS software and paired - sample t test showed that the subjects’ serum Ca, P and Mg concentrations involved fluctuation even after 24 hours had passed from regular body activity and did not return to its original and base clinical norm (P=0.006,P=0.0001 and P=0.0001, respectively). At this point, demand of cells for metabolic functions and repel of electrolytes via sweating increased; therefore, a significant decrease is observed in electrolytes of serum after 24 hours. The results showed the effect of exercise on the serum calcium, phosphorus and magnesium concentrations after 24 hours rest which did not return to baseline levels after a period of recovery (within 24 hours). Also recommended athleties, who participate in regular aerobic activities 2 or 3 times in a week, in addition to providing carbohydrate alimentary sources, take advantage of dairy products, vegetables, meat, fish, chicken, egg, and grains. Mean while, Vo2 max of subjects was significant after 16 sessions (P=0.0001).

THE EFFECT OF AEROBIC TRAINING ON CREATINE KINASE AND LACTATE DEHYDROGENASE REST TIME ON MALE ATHLETES

Pourvaghar, M., Shahsavar, A.
1. University of Kashan 2. University of Payame Nour (IPU), Iran

Creatine kinase (CK) is a key enzyme, which causes muscular cell metabolism and acceleration in conversion of creatine-to-creatine phosphate and vice versa. Lactate Dehydrogenase (LDH) is also another enzyme, which can be highly found in the cytoplasm of every tissue of the body with different concentration. By performance of athletic activity until exhaustion, some changes occur in muscles and blood such as the decrease in the potential of creatine phosphate and muscle’s ATP, the increase of lactic acid in muscle and blood and glycogen of muscle. CK and LDH are both anaerobic enzymes but it seems that in aerobic and long-term activities, which depend on intensity and duration of training, the stimulation and undulation in both enzymes.

This study aimed at investigating the rest changes of concentration of Creatine Kinase (CK) and Lactate Dehydrogenase (LDH) after aerobic exercise. For this purpose 12 male athletes were selected. Aim fully the subjects performed 16 sessions running exercises during 8 weeks. In the first four sessions, their heart rate was 140-150 and in the last four sessions 170-180 times per minute was controlled by Polar watch. About 3 cc as a blood sample was taken from the subject’s elbow vein before the exercise. In this process, their concentration average of CK and LDH enzymes in the rest mood and also maximum amount of oxygen consumption were analyzed by t-test formula. There was significant difference between CK serum (P= 0.023), LHD serum (P= 0.021) and VO2 max (P= 0.0001) which shows the effects of aerobic exercise on increase of anaerobic enzymes concentration which seems to be as the result of high degree of aerobic training sessions and also the result of muscular damage during the training period and even 24 hours after the stopping exercise and recovery.

With regard to the subjects' maximum consumed oxygen (VO2 max), after sixteen regular aerobic sessions meaningful results were obtained. It seems that regular aerobic trainings can improve athletes’ aerobic capacity and cause increase in their aerobic ability.

THE EFFECT OF AEROBIC EXERCISE ON SECRETION OF TRIODOTHYRONINE (T3), THYROXIN (T4) AND ITS STIMULATING HORMONE (TSH)

Shahsavar, A., Pourvaghar, M.
1. Payame Nour University (IPNU) 2. Kashan University, Iran

It is a well-known fact that exercise affects the activity of many glands and the production of their hormones. One of the glands affected is the thyroid. Thyroid gland secretes two separate amino acids: triiodothyronine (T3) and thyroxine (T4), whose importance on the regulation of general metabolism, growth, and tissue differentiation as well as gene expression has been known for a long time. This research...
has been conducted in order to study the changes of secretion of thyroid hormone i.e. thyroxine (T4), triiodothyronine triiodothyronine hormone (T3), and also thyroid stimulating hormone (TSH), following an aerobic activity. Group of 10 male university students with over three years experience in different fields of sport were participated in this semi-experimental research. The obtained average and standard deviations of factors such as age, height, weight and body mass index (BMI) are as follows: (23.1±1.65), (171.1±4.51), (68.5±4.8) and (21.4±1.11). The exercise training of this research consisted of 20 minutes of running around the track and field, which were 10 rounds each taking two minutes. Control of the exercise’s intensity was done through monitoring the rounds. In this research the blood samples (5 cc) were taken from participants before and after the aerobic exercise to measure the T3, T4, TSH and the laboratory method RIA was used to analyze and the blood samples. The achieved data from this research was analyzed statistically through using SPSS and MS word 2003. The results showed that aerobic activities did not have any significant effect on the amount of T3 and TSH secretion, although the results proved a basic change in T4. It seems that aerobic activities can have different reactions on the secretion of thyroid hormone while factors like hematocti, plasma decrease, as well as changes in pH of blood and also mental conditions may lead to a significant change in the concentration of hormone. The results of this research showed that the increase in the concentration was caused by the long duration of exercises. In this survey the concentration level of T4 had a 17.04% increase after 20 minutes of aerobic exercise (4000 Meters) which showed meaningful changes in secretion of T4 hormone. The effectiveness of the type of exercise on the secretion of T4 can be the reason for the increase of this hormone.

NEUROMUSCULAR FATIGUE DURING LOW- VS. HIGH-INTENSITY ISOMETRIC CONTRACTIONS OF PLANTARFLEXOR MUSCLES

Pääsuke, M., Rannama, L., Ereline, J., Gapeyeva, H.
University of Tartu, Estonia

The aim of the present study was to compare the fatigue-related changes in soleus motoneuron pool reflex excitability and surface electromyography (EMG) parameters, and maximal isometric voluntary contraction (MVC) force and twitch contraction characteristics of the plantarflexor (PF) muscles during repeatedly sustained low- (30% MVC) vs. high-intensity (70% MVC) isometric contractions. Twelve men aged 21 to 24 years participated in two fatigue tasks on separate days with at least 1-week interval. The fatigue task consisted of three sustained isometric contractions of PF muscles at a target force level until exhaustion separated with 2-min pause between contractions. M-wave (muscle compound action potential) amplitude (Mm), Hoffmann reflex maximal amplitude (Hm) to M-wave amplitude ratio (Hm/Mm), and root mean square amplitude (RMS) and median frequency (MF) of EMG power spectrum were recorded from the soleus muscle. Twitch contraction characteristics of PF muscles were measured by supramaximal electrical stimulation of posterior tibial nerve using square-wave pulses of 1 ms duration. The MVC force of PF muscles was reduced to a greater extent after the low-intensity compared to the high-intensity fatigue task. For the low-intensity fatigue task, isometric twitch peak torque of PF muscles was reduced (p<0.05) after each sustained contraction and during the recovery period. For the high-intensity fatigue task, this parameter was reduced (p<0.05) after the 1st sustained contraction and throughout the recovery period, whereas it did not differ significantly compared to pre-fatigue level after the 2nd and 3rd sustained contractions. The Mm recorded in soleus muscle remained constant immediately post-fatigue and during 15-minute recovery period compared to pre-fatigue level in both fatigue tasks, whereas Hm/Mm was significantly (p<0.05) reduced only after high-intensity fatigue task. The increase in RMS and decrease in MF during isometric contractions was greater (p<0.05) for low-intensity fatigue task compared to high-intensity fatigue task. The present study demonstrated that a reduction in maximal voluntary and electrically elicited force-generation capacity of PF muscles immediately post-fatigue was more pronounced in low- than high-intensity isometric contractions. Low-intensity isometric contractions, repeatedly sustained until exhaustion, resulted in a marked increase in the amplitude and spectral compression of the EMG signal without a significant post-fatigue reflex inhibition of soleus motoneuron pool. Repeatedly sustained high-intensity isometric contractions, however, resulted in post-fatigue reflex inhibition of soleus motoneuron pool and less pronounced spectral compression of the EMG signal during sustained contractions. A failure of neuromuscular transmission-propagation was not evident after repetitive fatiguing isometric contractions.

EFFECT OF PERCUTANEOUS ELECTRICAL STIMULATION OF KNEE EXTENSOR MUSCLES ON ISOKINETIC TORQUE AND POWER PRODUCTION PERFORMANCE

Pääsuke, M., Requena, B., Ereline, J., Gapeyeva, H., Kums, T.
University of Tartu, Estonia

This study examined the acute effect of a brief high-frequency submaximal percutaneous electrical stimulation (PES) of the knee extensor (KE) muscles on isokinetic torque and power production performance. We tested the hypothesis that the induction of posttetanic potentiation in KE muscles by a conditioning submaximal tetanic contraction evoked by direct PES would increase the concentric isokinetic knee extension peak torque (PT) and average power (AP) at slow and moderate angular velocities. Eighteen male physical education students aged 20-25 years participated in this study. Maximal voluntary isokinetic and isometric unilateral knee extension force production characteristics were measured using Cybex II isokinetic dynamometer. The subjects performed maximal voluntary concentric isokinetic knee extensions at angular velocities of 60 and 180 deg/s in control (CON) trial (without prior PES application), followed by a PES trial after 30 min rest period. In PES trial, a conditioning submaximal (25% of the maximal voluntary isometric contraction force) isometric tetanic contraction of the KE muscles was induced by a 7s direct PES at 100 Hz, interspersed after 3 min with testing of voluntary isokinetic performance. No significant differences in isokinetic knee extension PT and AP were observed between CON and PES trial at 60 deg/s. However, a significantly greater (p<0.05) isokinetic PT (8.9%) and AP (8.2%) were observed in PES trial compared to CON trial at 180 deg/s. There were few studies in which the posttetanic potentiation in human muscles has been induced by direct PES for enhancement of muscle performance. Our previous study (Requena et al. 2005) demonstrated that a conditioning submaximal tetanic contraction of triceps brachii and pectoralis muscles induced by high-frequency PES did not significantly change bench press throw performance. However, a great inter-individual variability was observed in this study. The present data indicate that the application of submaximal PES prior to maximal voluntary isokinetic knee extensions (kicks) can have a positive effect on performance primarily under the lower torque production conditions associated with the faster velocities, but not the higher torque production conditions at the slower velocities. Interpretation of any performance measure must consider the measurement error; this is equally essential in the case of isokinetic dynamometry (Divr
THE ENERGY COST OF ROCK DRUMMING: A CASE STUDY

Smith, M., Draper, S., Patter, C., Burke, C.
University of Chichester, United Kingdom

The energy cost of various forms of physical activity has received considerable attention (Ainsworth et al., 1993). However, despite being a physically demanding activity that could offer an alternative to more conventional forms of physical activity prescription; drumming has received little attention. The present case study investigated the energy cost of rock drumming during concert performance in a high profile drummer.

Subject was Clem Burke, drummer with the band Blondie (age 52 yr, height 1.80 m and mass 83.6 kg). All testing took place on 18th July 2007 and conducted on stage at the Manchester Apollo Theatre, England. Testing was in two parts, an incremental drumming test performed 6 hours prior to the concert performance, and the concert itself. Incremental test consisted of four 4 min stages followed by a fifth where the subject drummed to volitional exhaustion. Work rate of each stage was controlled via a click track that was audible to the subject via headphones (Sony, Japan). Starting work rate was 110 beats min⁻¹, increasing 20 beats min⁻¹ for each subsequent stage. Oxygen uptake (VO₂) and respiratory exchange ratio (R) were measured throughout using a portable analyser (K42b, Cosmed, Italy), and heart rate (HR) using short range telemetry (S810i, Polar, Finland). Concert HR was recorded throughout. Energy expenditure was calculated using indirect calorimetry from the respiratory data (using the final minute of each submaximal stage). This was used to calculate the relationship with HR using linear regression. This relationship was used to estimate energy expenditure from the concert HR data. Resting metabolic rate was calculated from the 2 min period prior to the incremental test. VO₂peak was defined as the highest 15 s moving average VO₂ during the test.

Incremental test peak HR was 191 b.min⁻¹ and VO₂peak was 2.02 L.min⁻¹ (24.2 ml.kg⁻¹.min⁻¹). Concert duration was 82 min 27 s, which included rest periods between songs and encore. Average HR for the entire concert was 145 b.min⁻¹ (range: 110-179 b.min⁻¹). Estimated energy expenditure from the concert revealed a rate of energy expenditure higher than those previously published for Bannister, E.W. and Brown, S.R. (1968) The Relative Energy Requirement of Physical activity. In Exercise Physiology (Falls, Ex. 25(1): 71-80) warrants further investigation as an area of physical activity.

Data showed that rock drumming is an intense and physically demanding activity. Peak HR was well in excess of age predicted maximum. Estimated energy expenditure from the concert revealed a rate of energy expenditure higher than those previously published for seated drumming (Bannister and Brown, 1968). We conclude that rock drumming demands a high level of energy expenditure and warrants further investigation as an area of physical activity.

NEUROMUSCULAR CONTROL OF POWER AND FATIGUE IN DYNAMIC BARBELL SQUAT EXERCISE

Brandon, R., Howatson, G., Hunter, G.
University of Stirling, United Kingdom

Background The Surface Electromyographic variables of root mean square amplitude (RMS) and muscle fibre conduction velocity (MFCV) have been used to study fatigue and recruitment during isometric exercise. In isometric contractions with no fatigue, RMSs and MFCVs both increase with force due to greater total recruitment and firing rates of motor units (MU). In prolonged submaximal contractions RMS also increases, whilst MFCV decreases, as changes in muscle metabolites slow MFCV, counteracting the influence of increased activation(1). Recently, similar findings have been shown in dynamic contractions, suggesting the potential for analysing MU recruitment and fatigue in resistance exercise(2, 3). The recruitment of fast twitch MU is important for a positive training effect and identifying the degree of central or peripheral fatigue could aid the optimisation of training volume. This study aimed to investigate the effect of load and fatigue on power and MU recruitment during dynamic squat exercise. Methods Nine strength trained male subjects performed 3x3 squats (3Ds) at 50, 75 and 100% of 3 repetition maximum (3RM). Subjects then performed 1 set of squat jumps (SJ) at 50% of 3RM until volitional failure. RMS and MFCV of VL muscle was recorded at 110 and 90° of knee flexion for DS and SJ respectively. MFCV was processed from cross correlation analysis of an electrode array and power derived from barbell displacement. Mean Power and normalised RMS were calculated for the concentric phase of DS and SJ. Results During DS, for 50, 75 & 100% 3RM RMS significantly (p<0.001) increased with load (56.5±12.2, 75.6±15.9, 99.2±15.7 %, while no differences were observed for power and MFCV. During SJ, for the first 3, middle 3 and last 3 repetitions MFCV and power, significantly (p<0.001) declined (6.89±1.94, 6.30±2.02, 5.30±1.81 m.s⁻¹ & 1920±1709±248, 1407±254 W) while no difference was observed for RMS. Summary This study has shown that 1) during DS, RMS increased alongside load while power and MFCV remained the same, suggesting a recruitment strategy may have been employed to maintain optimal power, 2) during SJ, MFCV reduced alongside power, whilst RMS remained the same, suggesting that peripheral rather than central factors may have caused the fatigue. The findings support the potential of RMS and MFCV analysis of resistance exercise.

DEVELOPMENTAL CHANGES IN COGNITIVE REACTION TIME

Iida, Y., Miyazaki, M., Ueda, Y., Shioda, K., Teramoto, K., Uchida, S.
Waseda University, Japan

Athletic training in children is not a simple procedure. Children develop ability during training while training itself affects ability development- as well as development of the central nervous system (CNS). Cognitive reaction is an important component in athletic performance; better understanding of its development should facilitate the design of efficient athletic and educational training plans for children.

Subjects were 6 to 12 year old primary school pupils from the first to the sixth grade (male: 61, female: 83). We sampled from a single private primary school to obtain subjects with comparable (relatively good) economic status and a wide range of physical abilities.

Subjects were instructed to press a button, but only when one of two colored targets appeared on a computer screen before them. These Go and No-go targets appeared intermittently across 100 trials presented for 300 ms duration at intervals of 1500 ms. We presented three discriminative conditions- 1. Simple reaction: Only one target color appeared (100% target). 2. High rate reaction: Target color appeared on 80% of trials. 3. Low rate reaction: Target color appeared on 50% of trials.

The relationship between subjects' age (months), median reaction time and error rates (both omissions and false alarm commissions) in the three target reaction conditions were analyzed using correlation analysis. This protocol was approved by the local facility's ethics committee. Informed consent was obtained after explaining all procedures and their risks to each child.

There were significant correlations between age and median reaction time in all three conditions (simple reaction: \( r = -0.76, p < 0.01 \), High rate reaction: \( r = -0.71, p < 0.01 \), Low rate reaction: \( r = -0.75, p < 0.01 \)). There were also significant correlations in the difference values for High and Low rate reaction minus simple reaction time (High rate reaction: \( r = -0.19, p < 0.05 \) and Low rate reaction: \( r = -0.42, p < 0.01 \) respectively). There was significant correlation between age and error rate in the High rate reaction condition (\( r = 0.23, p < 0.01 \)), but not in the Low rate reaction condition.

In this study, the high rate reaction task appeared to result in automatic button pressing, producing significantly lower reaction times than were found in the reactions to low rate trials. In both high and low rate reactions, the differences relative to simple reaction decreased with age, indicating that cognitive reaction time developed independently of the presumably underlying simple reaction abilities. Error rate also significantly declined with age, but only in the high rate reaction condition. The go/no-go task design has been widely used to examine the inhibitory characteristics of the central nervous system. The present results are interpreted to represent the development of inhibitory processing.

SELF-CONSCIOUS EMOTIONS IN SOCCER PENALTY SHOOTOUTS: CELEBRATE INITIAL SUCCESSES AND YOU WILL HARVEST ULTIMATE WINS

Moll, T., Jordet, G., Pepping, G.
University of Groningen, UMCG, Netherlands

Pride and shame are self-conscious emotions that are elicited when individuals focus their attention toward aspects of themselves. These emotions function to communicate whether one has lived up to certain social standards or not (Tracy & Robins, 2004). In the current study, we hypothesized that pride and shame would be expressed following potentially high self-focus sport actions: a kick in an important soccer penalty shootout. Research has shown that when participants view still-photographs of actors attempting to express pride and shame, both emotions seem to have distinct and recognizable non-verbal expressions involving body and face (Keltner & Buswell, 1996; Tracy & Robins, 2007). The first aim of our study was to create operational definitions of spontaneously expressed pride and shame and check if these could be used to classify aspects of post-shot behavior displayed in dynamic video images of penalty kicks. The second aim was to investigate whether individual differences in pride after goals are linked to the ultimate outcome of the penalty shootouts.

In total, 267 shots were analyzed from all penalty shoot-outs held in the World Cup and the European Championships. A coding instrument was developed to classify behavior as pride and shame. Chi-square tests were used to test the relationship between pride and game outcome (\( p < 0.05 \)). Results revealed that when players scored (n=202), 50% of them displayed celebratory hand moves. Here, 43% involved moves above head, 28% moves below head, 44% with one hand, and 25% with two hands. In addition, 8% of the players smiled, 7% looked up, 48% looked down, and 1% hid their face. When players missed (n=65), 77% of them looked down, 13% looked up, and 15% closed their eyes. In addition, 48% of the players hid their face, 35% did this with two hands and 12% with one hand. Finally, for all scored penalties, ‘celebratory hand moves’ was positively and significantly related to game outcome (\( p < 0.01 \)). This was also found when directly game-deciding kicks were excluded (\( p < 0.05 \)) and with a trend when kicks taken with an unequal score were excluded (\( p = .11 \)).

Our findings indicate that following a penalty kick, expressions of pride are displayed in response to success and expressions of shame are mainly displayed in response to a failure. Notable exceptions were the typical shame behaviors ‘looking down’ and ‘hiding the face’ that also were observed in response to success. More interesting however, players who show pride following a successful penalty kick seem more likely to ultimately win the penalty shoot-out, also when uneven standings in the shootout are controlled for. Possible reasons may be that displaying pride can create a sense of dominance which increases confidence in one’s own team and decreases confidence in the other team.

ORTHOREXIA NERVOSA IN SPORT: AN EATING DISORDER OR AN OBSESSIVE-COMPULSIVE DISORDER?
Iona, T., Ammendolia, A., Scarfone, R., Ferragina, A., Chiodo, S., Papaianni, M.C., Segura García, C.
University of Catanzaro “Magna Graecia”, Italy

Introduction
The Orthorexia nervosa (ON) is a new food pattern that has recently been related with eating disorders. While bulimic and anorexic patients focus mainly on the quantity of food, people affected by ON obsess on its quality. For this people the food is excessively important in their life. The aim of this study is to determine the incidence of the ON in sportsmen and to verify the association of ON with eating disorders, body image disorders or obsessive-compulsive disorders.

Methods
167 subjects, who regularly train in different sports (45.8% elite team), were enrolled and filled in the ORTO-15, the Eating Disorder Inventory 2 (EDI-2), the Eating Attitude Test (EAT-26), the Body Unessay Test (BUT) and the Yale-Brown Obsessive-Compulsive Scale for Eating Disorders (YBOC-S). Chi-square test, ANOVA (univariate) analysis and Spearman’s correlation were used for data analysis.

Results
Mean score to ORTO-15 test was 36.66±4.25 with no statistical difference regarding sex or level of training. More than 80% of subjects resulted positive to ORTO-15 (cut-off 40) so it was decided to attend a more severe cut-off (35) that gave 40.4% of sportsmen positive to test. There was no association between orthorexia and sex, level of training or kind of practiced sport. Mean scores of EAT-26, EDI2 and BUT were normal. Subjects positive to ORTO-15 also scored significantly higher to EAT-26 (p<0.05) and YBOC-S (p<0.05). No statistical differences were found in EDI-2 and BUT. Spearman’s correlation showed a strong correlation between ORTO-15 scores and prior or actual dieting, EAT-26, Drive for Thinness, YBOC-S and obsessions and compulsive behaviours regarding dieting, purging, physical exercise, weight and somatic control.

Discussion
Orthorexia nervosa is highly frequent among sportsmen despite the sport they practice. Sportsmen affected by ON do not show the characteristic body image alterations that eating disordered patients suffer. ON is specifically associated to obsessive-compulsive disorders and shows a strong correlation with rigid and pathological dietary patterns.

GOAL STRIVING AND AFFECTIVE OUTCOMES IN SPORT: AN EXPERIMENTAL INVESTIGATION OF ATHLETES’ RESPONSES TO SUCCESS AND FAILURE
Smith, A., Ntoumanis, N., Duda, J.
University of Birmingham, United Kingdom

Goal setting is promoted as a primary mental skill in sport, however, whilst the benefits of goal setting are recognized, athletes’ responses to success and failure following goal striving have received little attention. Grounded in self-determination theory (Deci & Ryan, 1985), the present study examined the role of motives underlying athletes’ goals in predicting tendencies towards self-aggrandizement following success and self-derogation following failure. The links of these tendencies with perceived enjoyment, tension, and psychological distress were also investigated.

Eighty-six British athletes (59 male, 27 female) were randomly allocated to one of two goal motive conditions and completed two cycle time trials, each with a personally-relevant distance goal. Using written instructions, the autonomous motive condition (n = 43) aimed to promote identified and intrinsic goal striving. In contrast, instructions in the controlled condition (n = 43) aimed to invoke internally and externally pressured goal striving. Manipulated feedback during the cycle trials ensured that participants experienced both success and failure in relation to their goals. Self-report measures of self-aggrandizement (self-praise prompted by an exaggerated sense of self-esteem) and self-derogation (self-criticism resulting from diminished self-esteem) were completed by participants following successful and unsuccessful trials, respectively. Perceived enjoyment, tension, and psychological distress were measured following the trials. Additionally, participants reported their personal motives for striving for each goal.

Manipulation checks showed that the instructions were correctly understood. In contrast to our expectations, the two conditions did not differ significantly on any of the outcome variables (Wilk’s = .97, F (1.78) = .517, p > .05). However, a number of interesting results emerged when looking at personal goal motives. Structural equation modeling analysis supported a model (scaled 2 (13) 15.72, p > .05, CFI = .98, NNFI = .97, RMSEA = .05 (CI = .00-.13), SRMR = .07) in which controlled personal goal motives were positively linked with both self-aggrandizement following success and self-derogation following failure. In turn, both self-aggrandizement and self-derogation were positively associated with perceived tension and psychological distress. Autonomous personal motives were unrelated to self-aggrandizement and self-derogation but were directly and positively linked to enjoyment.

The present study suggests that the personal goal motives athletes’ adopt during goal striving can predict athletes’ self-esteem related reactions following success and failure as well as related affective consequences.

THE RELATION BETWEEN PERFORMANCE AND PERSONALITY AMONG HUNGARIAN ELITE ATHLETES
Gyömőr, N.
Semmelweis University, Faculty of Physical Education and Sport Sciences, Hungary

A number of factors are tied into understanding, predicting and enhancing athletic performance. The dispositional characteristics like personality characteristics are one of the most important. The clinical sport psychology highlights the importance of personality. This study suggests an approach in the area of personality and performance analysis, which combines the questionnaire and projective tests. Beside this it also reveals the application of the projective tests in the area of sport psychology. The advancement of these is that they are dynamic and they indicate not just the performance, but also the way to it. Therefore the roots of the performance problems can be revealed. The study was conducted among 43 hungarian elite athletes. In the aspect of the sportpsychological measurements I used the following measurements: ACI-28, CSAI-2 (questionnaires), and Wartegg-test and Szondi-test (projective tests). The aim of the questionnaires was to measure the performance anxiety, and the goal of the projective tests was to measure the connected personality characteristics. According to the results I found that among athletes with significant anxiety (p<0.05), the anxiety influences the identity, the development of the emotional-relational life as well as the handling of anxiety and aggression. According to the analysis of the projective
tests, the results reflect similar mental constitution. Sport became an integrated part of the personality, therefore the question of performance has a very emphasized role. It also affects the development of personality, certain areas develop in different time, thus the emotional life sometimes slackened, or even hampered, which influence the social relations. The study describes a different approach of understanding and analysing the relation between performance and personality, and gives a new possibility to the theory and practice of the sport psychology.

THE INFLUENCE OF TIME OF EXERCISE ON DECISION MAKING IN YOUNG BASKETBALL PLAYERS

Estevês, P., Araújo, D., Barreto, H.
Technical University of Lisbon, Portugal

INTRODUCTION: The decisional behavior plays a prominent role for the achievement of a high-level performance in basketball. The ecological dynamics perspective considers the decision making as an emergent process that results from the interaction of organismic, environmental, and task constraints (Araújo, Davids & Hristovski, 2006). In the literature, the increasing time of practice is associated to a condition of fatigue that inevitably conducts to a deterioration of the performance. However, recent investigations have shown that task-specific fatigue facilitates decision making in skilled players (Royal et al., 2006). The aim of this paper is to analyse the influence of the time of exercise in the decisional behavior of young basketball athletes, during a training session.

METHOD: Six male basketball players (16-17 years old) participated in this study. The athletes were analyzed in three training sessions of three consecutive microcycles where, during two time slots of each session, they played constrained games of three-on-three that were at the same time recorded. In three different moments of the session they also performed the perception of effort test (Borg, 2001) and the Bosco et al., (1983) protocol that evaluates the anaerobic power. A notational analysis system, composed of several categories, was created to study the decisional behavior of the attacking player in game.

RESULTS: A tendency to increase in the perceived exertion was identified along the training session. In what relates to the anaerobic power production there was a non significant impact of the time of exercise. The quality of decision making increased in the training session, specifically in the ratio shots attempted/ shots converted.

DISCUSSION: The results suggest an adaptation of the athlete to the time of exercise, expressed by the increasing decisional efficiency in the game. Following a constraints-led approach, these results may be interpreted as a self-organizational process, between the different organismic systems, whose solution brings together internal and external constraints to achieve task goals. Moreover, a refinement in the perceptual tuning into the relevant information in the game may have contributed to a better adjustment of the perception-action relationship coupling.

BALL TOSS AS BI-DIMENSIONAL AND TEMPORAL ANTICIPATORY INDICATOR OF TENNIS SERVE DEEP IN A FEMALE PROFESSIONAL PLAYER; STUDY CASE

Zawadzki, P., Roca, J., Vallejo, L.
Barcelona University, Spain

The hypothesis assumed in this study considers the ball toss in tennis serves as a performance indicator to the return player. In the studied case, variability of a professional female tennis player (top 60 ranking WTA-Woman Tennis Association) was analyzed during three official matches. A Sony Handycam model DCR-HC23E (Sony Corporation, Japan) was used for the image capture, the software Spadix JRulerPro v.3.0.0.1 to spatial coordinates, and the software CCC-FairPlay Lite v.3.0.14 to temporal data. The sample of 33 serves was examined, and normalized by 4 moments: a) ball leave the hand, b) maximum high of the ball, c) impact with the racquet, and d) position of landing in the service square, all measures were done in spatial (cm) and temporal (s) data. A linear regression model was calculated to predict variables using moment as dependent variable. The resume shows an R=0.89 (p<0.00) to moment dY in relation to the predictors variables (except to variable time of ball toss). Considering that dY report the distance among net and serve line, the results appointments that dY (r=0.86), dY (r=0.81) and dY (r=0.85) can predicts the deep oscillation of service, but just dY (r=0.85) presented p<0.00. We concluded that dY might be applied directly on training protocols and also develop a base to form the knowledge about perception in tennis serve, especially respect psychological constancies and configurations.

PRECOMPETITIVE ANXIETY, GUM CHEWING, AND DIAPHRAGMATIC BREATHING

Hashim, H.
Universiti Sains Malaysia, Malaysia

The study was designed to examine if differences in the level of somatic anxiety, cognitive anxiety, and self-confidence exist among male recreational basketball athletes who were receiving gum chewing, diaphragmatic breathing, and a control intervention. The Competitive State Anxiety Inventory - 2 (CSAI-2; Martens, Vealey, & Burton, 1990) was administered to 30 recreational basketball athletes from a college in the New England Area. A total of three 3 x 3 mixed factorial Analysis of Variance was computed for the three subscales of the CSAI-2. Additionally, Pearson’s correlation coefficients were calculated for the cognitive anxiety and self-confidence subscales scores and self-confidence and basketball shooting scores. A significant interaction between experimental treatments and testing periods was found in the somatic anxiety subscale. Gum chewing group reported significantly lower levels of somatic anxiety postintervention when compared to the control group. No other interactions between experimental treatments and testing periods in the cognitive anxiety and self-confidence subscales of CSAI-2 were found. No associations between the scores of self-confidence and cognitive anxiety and the scores of cognitive anxiety subscales and basketball shooting performance were found. The results suggest a possibility of applying gum chewing as an alternative technique of somatic anxiety regulation.

WAS SURVEY RELATIONSHIP BETWEEN PHYSICAL FITNESS WITH ANXIETY AND DEPRESSION OF MALE STUDENTS IN THE GUIDANCE SCHOOLS

Sadeghi Boroujerdi, S.
University of Kurdistan, Iran

Adolescence in reason to intuitive specific problems and family, study and social problems have been more exposed to nervous pressure such as anxiety and depression. Psychological and educational researchers always like to discover new ways for prevention and reduction of psychological disorders among students.

The purpose of this study was survey relationship between physical fitness with anxiety and depression of male students in the Guidance schools.

Statistical population includes students in the Guidance schools and 350 of them were participated in this research. The research method was based on correlation. Data analysis includes descriptive statistical and Pearson Coefficients Correlation. The value of (P<0.01) was considered as significant.

The results of descriptive statistics showed that:
1. students had been similar physical fitness and their situation was sub norm of province. Thus, they hadn’t a favorite situation.
2. at anxiety, average score showed that there were rates of A=anxiety and they hadn’t favorite situation.
3. at depression factor, average score showed that there was a little depression in them.

Hypothesis tests results showed that:
1. There weren’t significant relationship between Physical Fitness with Anxiety and Depression in male Students at Guidance Schools.
2. There were significant relationships between Anxiety and Depression in male students at Guidance Schools.

EFFORT PERCEPTION IN MULTIATHLON ATHLETES

Rubio, K., Godoy Moreira, F.
University of Sao Paulo, Brazil

Introduction Multiathlon is a multisport competition that involves modalities as running, jumping, swimming, cycling, canoeing, throwing, MTB, obstacle running, climbing, skating, apnea, bow and arrow, that occurs in just one day. It is a competition of individual character, and none of the modalities is obligatory, even though exist a minimum number that has to be done according with the category of the competitor. The pursuit of limits is one of the major points of this type of competition, which leads the athlete to a constant overcome of the physical demand and pain. The goal of this study was to evaluate the dimension of pain suffered on male athletes participants of the multathlon 2007 edition in Brazil. Methods It took part in this study 11 male athletes of a total of 27 participants, with ages between 24 and 43 years that participated all of the competition. Was used Borg’s scale in two moments of the competition, on the beginning at 4:00 AM and near the final at 6:00 PM when different types of effort had already taken place. Results The results point out that we present levels of perception of effort that go from somewhat hard to hard, and they reach maximum limits of Borg’s scale of hard to extremely hard, as much at the initial moment of the test as on the end. Some athletes presented a high level of effort in the beginning of the test, indicating a relation between perception of effort and its representation during the competition with high level of physical demand.

Discussion/Conclusion We observe in this study that the variation of the pain threshold among athletes of the same gender, corroborating the affirmation that pain perception besides being subjective it is a cultural construction related with the individual history of life. The high effort level in the beginning of the competition suggests that the perception of the effort is associated with the future representation of the effort, in other words, knowing the fact that still there are going to be lots of different modalities on the competition with different demands, of effort motor skill, this can take them to a competitive stress symptom. That permits us to affirm the existence of a relation among social representation of the effort and it’s perception, as all the athletes that ended the competition conquer first classifications presented some type of lesion, because they disrespect pain as a sign of something’s wrong.

MANIPULATION OF POSITIVE AFFECT IN SPORT CLIMBING USING MUSIC

Spiridon, E., Marques-Bruna, P.
Edge Hill University, United Kingdom

Introduction
Pre-competition readiness demands fine tuning of positive and negative affects (Hanin, 2000) in order for athletes to achieve an individual zone of optimal functioning (IZOF). Many coaches use music as an affect manipulator; however, some qualitative studies (e.g., Giacobbi and Weinberg, 2000) have reported that expert athletes already display greater positive pre-competition affect than non-athletic populations. This suggests that music may only bias affect in novices and non-climbers. Thus, this study aimed to 1- investigate differences in affect between non-climbers, and novice and expert climbers, and 2- test the validity of music for the manipulation of affect in climbers. The findings may be used by sport climbers to consider music bias during competition.

Method
Thirty five non-climbers, 33 novice (4c-5c French RSD) and 32 expert climbers (6a to 7c+) completed the I-PANAS-SF (Thompson, 2007) before and after listening to validated valence music (Moare and Oakford, 2002). Differences between four affect scores (positive, negative, pre-test and post-test) at the three levels of expertise were assessed using MANOVA (p < .05) and post-hoc t-tests (p < .02). The effectiveness of affect manipulation by means of music was tested by comparing pre-test positive affect to post-test positive affect and pre-test negative affect to post-test negative affect for three music treatments (positive, negative, no-music) using independent samples t-tests (Bonferroni-adjusted alpha = .025).
Results
The MANOVA test showed significant differences in affect between expertise levels (F[8,188] = 2.25, p = .03, Wilk's lambda = .83, power = .86). The post-hoc t-tests revealed significant differences in positive affect between novices and experts only (p < .02), with novices scoring higher on post-test positive affect (16.3 ± 3.9) than experts (13.6 ± 4.2). Only positive music had a significant influence on affect, whereby positive affect increased significantly (t[30] = 2.49, p = .02) and negative affect decreased significantly (t[30] = 3.34, p = .02).

Discussion
The results confirm that participation in sport is a generator of positive affects, as suggested by Giacobbi and Weinberg (2000), and that only happy music is suitable for attuning positive affect, in agreement with Moore and Oaksford (2002). Novices expressed higher positive affect following the application of the music condition, while affect did not change substantially in experts. Such findings confirm Hanin's (2000) IZOF proposal that experts control their affect in a way that might assure optimal performance. During climbing competitions, the bias of music in the performance of climbers should be acknowledged.

THE IMPACT OF EMOTIONS ON PATTERN RECOGNITION OF CLIMBING WALL ROUTES

Spiridon, E., Marques-Bruna, P.
Edge Hill University, United Kingdom

Introduction
Previous research on the enhancement of wall route recognition in sport climbing is limited to the study of acquisition of chunked climbing route configurations in the form of affordances (Gibson, 1979; Boschker et al., 2002). Also, the effect of emotions on performance at different levels of expertise has received little empirical attention. Thus, this study aimed to investigate whether emotions have an impact on the ability of non-climbers, novice and expert climbers to recognise climbing wall route patterns. If affect influences performance in climbers, awareness of emotional bias should be brought to the attention of all climbers.

Method
Thirty five non-climbers, 33 novice and 32 expert climbers listened to validated valence music (Moore & Oaksford, 2002). A follow up cognitive task involved pattern recognition of 20 pairs of digitised climbing routes, presented on a computer screen at 16-s delay intervals, and the completion of a post-test inventory of memory and perception methods (Garden et al., 2002). The multivariate effects of expertise level and music condition (positive, negative and control) on pattern recognition scores, method of memorising and method of perceiving were assessed using a 2 x 3 x 3 MANOVA test (p < .05) and Bonferroni post-hoc tests (p < .02).

Results
The results of the MANOVA test were significant (F[6,178] = 12.05, p < .001, partial eta2 = .29, Wilk's lambda = .51, power = 1). There were differences in expertise level regarding pattern recognition scores (F[2,91] = 6.79, p < .002), method of memorising (F[2,91] = 27.98, p < .001) and method of perceiving (F[2,91] = 6.71, p < .001). Differences in pattern recognition scores were only statistically significant between non-climbers and expert climbers (t[65] = 9.01, p < .001) in all music conditions. Positive music improved method of memorising at all levels of expertise compared to negative music, however the differences were not significant (t[31] = 1.27, p = .05). Negative music (1.40 ± .52) was detrimental to functional perception of the wall in experts (t[31] = 27, p < .02) compared to positive music (1.82 ± .41).

Discussion
In agreement with Boschker et al. (2002), expert climbers showed superiority in pattern recognition scores and method of memorising of the climbing wall and suffered no interference from emotions. However, negative music perturbed the perception of the climbing wall in expert climbers; thus, contradicting Gibson’s (1979) theory of perceived affordances. The findings suggest that climbers may remember the functional parts of the route, however under a negative mood even expert climbers may not be able to choose the best route available.

DIFFERENCES IN PERCEIVED EXERCISE BENEFIT AND BARRIER INTENSITIES OF EXERCISING AND NON-EXERCISING FEMALE UNIVERSITY STUDENTS

Parker, J., Lovell, G.
University Of Gloucestershire, United Kingdom

Research has identified positive health benefit linked to physical activity (PA) in young and youth adult populations (Buckworth, 2001). An area that has been successful in raising levels of awareness as to the possible antecedent events that contribute to low levels of PA is our understanding of barriers to exercise. Findings have revealed that as barriers to exercise increase the frequency of (PA) participation decreases. However, many studies have failed to obtain a homogenous sample. The purpose of this study was to investigate the differences between exercising and non-exercising female university undergraduates.

A sample of female students (n = 101, Mean Age = 19.16, SD = 1.03) were recruited from a university in the South West of England. Non-exercisers were classified as individuals not meeting the ACSW (2000) recommendation of a minimum of 30 minutes of moderately intense cardio, five days a week. All participants completed the Exercise Benefits/Barriers Scale (EBBS, Sechrist, Walker & Pender, 1967). Independent t-tests demonstrated that exercisers had significantly lower total barrier scores (p < 0.001) and significantly higher benefit scores (p < 0.05). MANOVA's performed on the EBBS barrier/benefit sub-scales demonstrated significant group main effects F (4,116) = 5.885, p < 0.001, F (6,114) = 5.319, p < 0.001, respectively, with exercisers recording higher benefit and lower barrier scores. Subsequent univariate analysis found each of the subscales to be significant with the non-exercisers recording higher barriers and lower benefits. Family encouragement and physical exertion were seen to be the greatest perceived barriers to exercise in both groups while psychological outlook and social interaction the greatest benefits.
As hypothesised there was an overall trend with exercising females recording lower barrier scores and higher benefit scores than their non-exercising counterparts. However, an interesting result obtained from this study was that both groups found physical exertion to be the highest perceived barrier to exercise. This suggests that future interventions should design and focus health promotion strategies towards reducing the perceptions of fatigue and hard work associated with physical exertion.

IS GENDER ROLE ORIENTATION A PREDICTOR OF BODY RELATED PERCEPTIONS OF ATHLETES?

Asci, F., Mulazimoglu, B., Kirazci, S.
Pamukkale University, Turkey

The purpose of this study was to investigate whether the gender role orientation of athletes is related to their body related perceptions. This study was also aimed to determine the differences in body related perceptions with respect to gender role classification.

172 female (M(age)=19.12, SD=4.75) and 157 male (M(age)=21.26, SD=5.52) Turkish athletes from variety of team and individual sports voluntarily participated in this study. Bem Sex Role Inventory, Social Physique Anxiety Scale and Berscheid, Walster and Bohrnstedt Body Image Questionnaire were administered to 329 athletes. Stepwise Multiple Regression procedure was used to determine whether gender role orientation might predict social physique anxiety and body image satisfaction.

Results of Multiple Regression Analysis indicated that masculinity was significantly related to social physique anxiety (R=0.24) and body image dissatisfaction (R=0.48, p < .01) for 329 athletes. The masculinity score predicted 6% and 23% of the variance in social physique anxiety and body image satisfaction, respectively. The results of Stepwise Multiple regression for each sex revealed that both masculinity and femininity were significantly and positively related to body image satisfaction (ß=0.21 and ß=0.30, respectively) for females. However, masculinity was only predictor of body image satisfaction of males (ß=0.44, R2 = 20%, p<0.01). Furthermore, results indicated that femininity was significantly and negatively correlated with social physique anxiety of female athletes (R=0.28, p<0.01) and was the most important predictor of it (R2 = 8%). Beside, either femininity or masculinity was related to social physique anxiety of male athletes. 2 x 4 (Sex: Male/Female x Gender Group: Masculine/Feminine/Androgynous/Undifferentiated) MANOVA was conducted to test the differences in social physique anxiety and body image satisfaction among different gender role categories. MANOVA analysis demonstrated overall significant main effect of sex (Hotelling's T2 =0.14; F (2,196) =13.30; p < 0.01) and gender categories (Hotelling's T2 =0.22; F (6,390) = 7.22, p < 0.01) on body related perceptions. Univariate follow-up analysis indicated that female athletes were less satisfied with their bodies and experienced more social physique anxiety than male athletes (p<0.01). Furthermore, androgynous athletes were more satisfied with their bodies than athletes in other gender role categories (p<0.01).

It can be concluded that gender role orientation of athletes is a valid predictor of their body related perceptions and the contribution of gender role orientation to body related perception is changed with regard to sex.

CONTROL OVER THE LEVEL OF PHYSICAL PREPAREDNESS OF PUPILS OF MULTI-DISCIPLINE SPORTS SCHOOL AS A FACTOR OF GROWTH OF SPORTS MASTERY

Maklakova, V.
Daugavpils University, Latvia

At present, in connection with commercialization of all the spheres of human activity including the sports the price of victories has increased impressively. This induces both trainers and sportsmen to increase the capacity and intensity of training load steadily, which affects the level of physical preparedness that plays a top-priority role. Determining the level of physical preparedness according to the results of motive tests we acquire the possibility to develop lagging physical qualities using the influence of means and methods of physical upbringing. Correction of these qualities will give the possibility to increase sports mastery. For that it is necessary to accomplish the following tasks: first of all, to determine and choose the tests of combined competitions for all the specializations of a sports' school; secondly, to work out a system of evaluation of results according to T-scale; thirdly, to draw up evaluative tables. The work has been carried out on the basis of a combined sports school. At sports school the following kinds of sport are offered: football, fencing, shooting, weight-lifting, biathlon.

The method of testing has been used for determination of level of physical preparedness. The most effective tests have been chosen from a multitude of them. You can conduct these tests both on the sports ground and in the gym.

Testing has been conducted in the form of competitions consisting of three stages from April to November, 2007. At the first stage (April) 243 sportsmen took part. At the second stage (July) 266 sportsmen took part. At the third stage (November) 240 sportsmen took part. During tests control of absolute indices has been conducted, where measurement has been carried out in natural values (meters, centimeters, seconds etc.). The winners of competitions were the sportsmen with high level of physical preparedness, at the same time they had the high level of special training and were rated high in their kinds of sport.

REPORTED USE OF ANABOLIC STEROIDS AND ERGOGENIC SUBSTANCES IN GYM/HEALTH CLUB SETTINGS: ASSOCIATIONS WITH PSYCHOSOCIAL AND EXERCISE BEHAVIOR FACTORS

Palmeira, A., Rocha, M., Matos, M.
University Lusófona de Humanidades e Tecnologias and Faculty of Human Movement, Portugal

Purpose: The aim of present study was the analysis of the association among exercise behavior, psychosocial factors and the use of ergogenic substances in males who exercise in gym settings.

Methods: The sample comprised 147 male subjects (age M=27.4, SD=7.1) y representing individuals that exercise regularly in gym/health clubs in the Lisbon area which have equipment for training with high loads (exercise frequency M=4.3, SD=1.3 times/w; duration M=72.7, SD=27.7 min). Self-report measures evaluated: a) use of ergogenic substances (e.g., nutritional supplements; mass gainers; anabolic...
steroids), b) exercise behavior (frequency, intensity and duration), and c) psychosocial: exercise dependence (EDS-21), drive for muscularity (DMIS) and theory of planned behavior (TPB) about the use of ergogenic substances.

Results: A third of the subjects have declared the use of anabolic steroids (AS), whilst two thirds use ergogenic substances other than AS (mainly mass gainers). This use was associated with exercise dependence, drive for muscularity and the TPB constructs (all p<0.01, except for social norms which were non-significant). Exercise behavior was also associated with the use of AS (duration p<0.05 and intensity p<0.001) and other ergogenic substances (frequency p<0.01 and intensity p<0.001). The subjects with secondary exercise dependency (i.e. high levels of exercise dependence and high levels of drive for muscularity) showed marginally higher use of AS (p=0.071) and higher intake intention (p<0.01). The multivariate analysis, with multiple mediation testing following Preacher and Hayes procedures (2007), showed that intake intentions associations with reported use of AS were not mediated by exercise dependence or drive for muscularity. The multiple mediation analysis with the other ergogenic substances derived in an identical set of results; no mediation of the psychosocial variables on the intake intentions association to the reported use.

Conclusion: The reported use of AS was more than 10% higher than usually reported in the literature (Cole et al, 2003). The reported use of ergogenic substances were associated either to the exercise behavior factors and the psychosocial constructs evaluated in this study. In the latter factors, intake intention, exercise dependence and drive for muscularity were particularly associated to the reported use of ergogenic substances and AS. These constructs should be considered for the evaluation of exercise maladaptations that, paradoxically, are jeopardizing the health of the exerciser.

RELATIONS BETWEEN EXERCISE, QUALITY OF LIFE AND SELF-EFFICACY IN PERSONS WITH AND WITHOUT PHYSICAL DISABILITIES
Kontou, M., Katartzi, E., Theodorakis, Y.
University of Thessaly, Aristotle University of Thessaloniki*, Greece

Quality of life achievement was the purpose of many researches last years. Many of them examined the importance of quality of life in persons with and without disabilities. Quality of life are universally related to a) personality characteristics (Diener & Lucas, 1999), b) socio-demographic characteristics (Mroczek & Kolarz, 1998, Nolen-Hoecksema & Rustling, 1999), c) factors such as positive and negative affect, stress, physical health (Morris, 1999) and d) subjective life satisfaction (Berger & Molt, 2001). The purpose of the present study was to investigate the relations between exercise, quality of life and self-efficacy, in persons with and without physical disabilities. A sample of 375 persons in a range between 19 to 63 years old (Mage=33.5, SD=9.7) participated in the study. Of the participants, persons with physical disabilities were 182 (men=135, women=47) and without disability were 193 (men=137, women=62). The 53.3% (N=79) of people with disabilities and the 52.8% (N=102), of people without disabilities remarked that participated in physical activities. Participants completed questionnaires concerning quality of life, self-efficacy and exercise behavior. The results indicated that according to quality of life, exercise, persons with and without physical disabilities differed significantly in the values of physical health and self-efficacy but there were no differences in mental health. Between people participated or not in physical activities, appeared significant differences in quality of life and self-efficacy. Participants in physical activities indicated higher values comparing with no participants. Moreover for the individuals with and without disabilities, correlations were high between exercise behavior, quality of life and self-efficacy. The results indicate the effect of participation in physical activities in improvement of quality of life and self-efficacy in persons with and without physical disabilities.

DROP-OUT IN RHYTHMIC GYMNASTICS: AN EXPLORATORY INVESTIGATION
Di Cagno, A., Guidetti, L., Baldari, C., Battaglia, C., Massaro, A., Gallotta, M.
Istituto Universitario di Scienze Motorie, Italy

Every year about 35% of athletes withdraws from the sport (Riewald, 2003). The drop-out is typically between 10 and 17 years (Gould and Horn, 1984), age in which rhythmic gymnastics reach the best results. Aims of this study were to focus reasons for drop-out in Rhythmic Gymnastics and to identify gymnasts’ morphological and psychological characteristics for predicting persistence in competitive sport career.

Sixty dropouts elite gymnasts (33 international and 27 national level gymnasts) were administered a modified questionnaire about drop-out reasons. The questionnaire examined the following variables: drop-in age, drop-in motivation, training amount per week, age and morphological characteristics at the time of the best competition results, and reasons for exercise adherence. According to most studies (Johns et al, 1990, Weiss and Petlichkoff, 1989) concerning the drop-out phenomenon, socio-psychological aspects were the most frequent reasons of drop-out. The drop-out reasons for international and national gymnasts respectively were the following: morphological change (10.0%, 13.5%), lack of free time (19.0%, 15.0%), study (13.5%, 13.5%), injury (7.0%, 8.4%), lessenng of motivation (15.0%, 20.0%), lack of competitive success (2.0%, 5.0%), relationship problems with coaches (7.0%, 3.4%), age (10.0%, 2.0%), diet (2.0%, 0.0%), family (2.0%, 0.0%), lack of sports structures (2.0%, 3.4%), anxiety before competition (0.0%, 2.0%), and other reasons 19.1%, 15.2%

Data were analyzed using a t-test to verify significant differences between group answers. The drop-out’s product moment correlation was used to examine the relationship between persistence in competitive sport career and investigated variables. Significant differences between international and national gymnasts were found for training amount (p<0.01), age of the best results (p<0.05) and age of drop-out (p<0.01). The results revealed a significant correlation between the drop-in age (r=0.597 p<0.05), the training amount per week (r=0.447 p<0.05), the age of the best competition results (r=0.426 p=0.05) and the persistence in competitive sport career. Lack of motivation and of free
The results are discussed with reference to the conceptualization and measurement of transformational leadership, and informing these relationships. However, performance level was shown to moderate the relationship between transformational leadership, team cohesion, and performance level. Furthermore, results demonstrated that the leadership behaviours of coaches on how their leadership behaviours may influence cohesion depending on level of performance.

Callow, N., Smith, M., Hardy, L., Arthur, C. Bangor University, United Kingdom

MEASUREMENT OF TRANSFORMATIONAL LEADERSHIP AND ITS RELATIONSHIP WITH COHESION AND PERFORMANCE LEVEL

It is established that coaches’ leadership behaviours play an important role in successful sporting performance (e.g., Gould, Greenleaf, Chung, & Guinan, 2002). However, within the sport context, the conceptual and theoretical examination of these leadership behaviours in relation to transactional and transformational leadership theory is limited (see Rowold, 2006). Given the predominance and relevance of this theory in other contexts (e.g., Rafferty & Griffin, 2004), the lack of research in sport is surprising. In an attempt to bridge this research gap, the present study developed, and explored, the validity of a transformational leadership measure for sport. Further, the relationship between transformational leadership, team cohesion, and performance level was examined.

It is established that coaches’ leadership behaviours play an important role in successful sporting performance. Research Quarterly for Exercise and Sport, 73, 175-187.

Three hundred and nine club standard ultimate frisbee players (Mean age = 24.3 years, SD = 3.9) completed an adapted version of Hardy, et al’s in press Transformational Leadership Inventory and the Group Environment Questionnaire (Carron, Widmeyer, & Brawley, 1985). Confirmatory Factor Analysis revealed factorial and discriminant validity for the leadership inventory, with certain leadership behaviours discriminating between high and low performance level. Furthermore, results demonstrated that the leadership behaviours of fostering acceptance of group goals, high performance expectations, and individual consideration significantly predicted task cohesion; and fostering acceptance of group goals significantly predicted social cohesion. However, performance level was shown to moderated these relationships.

The results are discussed with reference to the conceptualization and measurement of transformational leadership, and informing coaches on how their leadership behaviours may influence cohesion depending on level of performance.

Examining the Sub-Components of Transformational Leadership. The Leadership Quarterly.

EFFECTS OF MENTAL TRAINING IN THE LEARNING OF A COMPUTER PSYCHOMOTOR TASK

Silva, C., Rosado, A., Fialho, S., Borrego, C., Bernardo, N.

ESDRM- Sport Sciences School of Rio Maior, Portugal

The primary aims of the present study were to investigate whether individualized imagery interventions had an effect on the learning of a motor task. Measures of the learning output were velocity and error frequency of a motor task, namely, in a computer car race game. Thirty-six undergraduate students (M age = 21.66 years, SD = 1.46) volunteered for the present study. The majority of the sample was majoring in Sport Sciences. Participants were not financially reimbursed for their participation and volunteered to be in the study. Written informed consent was obtained from each participant after he/she had read a letter of information and had any questions answered satisfactorily. Participants’ trials were conducted in a laboratory, accompanied only by an investigator. Upon completion of a first trial set and initial evaluation participants were randomly assigned to one of three groups, two experimental groups and a control group. Experimental group 1 was submitted to a motor training process; experimental groups 2 to a motor and mental practice program and the control group doesn’t have any activity between initial and final evaluation. Group 1 completed 10 sessions of 6 game trials with a 2 min of interval between each trial. Group 2 practice in the same conditions but mental imagery training took place after the completion of each trial followed by a 3 min interval. An imagery script was created for imagery practice. The script included two minutes silence with the following MG-M images: image of movements and feelings during race preparation, mental race practice and imaging arriving at the end of the race. The intervention was administered to the participants separately in a quiet and comfortable place and lasted for around eight and a half minutes. We found significant differences between Experimental Groups and the Control Group (p<0.009) favoring the Experimental Groups. However we didn’t found significant differences between the motor practice group and the motor and imagery practice group disfavoring the hypothesis that imagery facilitated the performance in this particular task. This study provides preliminary evidence for practitioners who wish to employ imagery interventions to enhance performance.

VISUAL PERCEPTION AND VISUAL-MOTOR INTEGRATION IN CHILDREN WITH DEVELOPMENTAL COORDINATION DISORDER

Tsai, CI., Hsu, YW.

National Cheng Kung University, Taiwan

Background: The purpose of this study was to explore the performance of visual perception and visual-motor integration in children with developmental coordination disorder (DCD), and the relationship between.
Methods: Fifteen children with DCD, aged 9–10 years, and 15 age- and sex-matched normal children were selected and assessed with Movement Assessment Battery for Children (Movement ABC), Test of Visual-Perceptual Skills (non-motor)–Revised (TVPS-R), and the Beery-Buktenica Developmental Test of Visual-Motor Integration (VMI), with Supplemental Developmental Tests of Visual Perception and Motor Coordination.

Results: The results showed that children with DCD performed significantly worse than normal children for all tests, except for Visual-Figure Ground subtest in TVPS-R and Motor Coordination subtest in VMI. Especially, these clumsy children in Taiwan performed more poorly on Visual Discrimination and Visual-Form Constancy subtests in TVPS-R. But, the deficits of all TVPS-R and VMI subtests were not common to all children with DCD. Finally, for both groups, there was a significant moderate correlation between visual perception and visual-motor integration, indicating that visual perception problems are associated with motor ability.

Conclusions: The above-mentioned findings confirm most of the previous studies that children with DCD have poor perceptual and motor performance. However, the heterogeneity of children with DCD, and the task differences of specific instruments should be further examined.

Key words: developmental coordination disorder, visual perception, visual-motor integration

PERSPECTIVES ON THE DEVELOPMENT OF COACHING EXCELLENCE: A QUALITATIVE INVESTIGATION INTO PSYCHOLOGICAL FACTORS OF COACHING CONCEPTS OF PROFESSIONAL SOCCER COACHES IN JAPAN

Kitamura, K., Nagayama, T., Saito, S.

Tohoku University, Japan

The purpose of this study was to describe the developmental process of perceptions of coaching concepts of professional soccer coaches in Japan. Participant selection was limited to coaches of professional soccer club in Japan who had accumulated a minimum of five years top league level of coaching experience. Participants were further limited to full-time coaches, defined as having 60% or more of their work allocated to coaching tasks. Six professional soccer coaches in Japan served as participants for this study. Their average age was 46.3 years old, and they had an average of 9.7 years of coaching. In-depth, open-ended interviews were conducted with each coach. Interviews ranged between 60 to 90 minutes, were tape recorded with the permission of the participants. The interviews were systematically transcribed verbatim from audio tapes immediately after the completion of each interview, and total of 549 meaning units were extracted from the data set. The data was decontextualized using an inductive procedure for analyzing unstructured qualitative data (Colt, Salmela, Barra, & Russell, 1993). The inductive analysis process resulted in regrouping these interview transcripts into three categories (recognition of self-change, refinement of coaching skills, and cultivation of players’ mind) and sub-categories (pondering, self-accept, awareness, vision, rationalization, feedback, communication skills, decision making of players, responsibility, and self-coaching).

All of the participants faced a lot of problems and built up their unsuccessful experiences throughout their coaching career. Consequently, they realized the needs of self-change to develop their coaching expertise. Evidence of the coaches’ mental conflicts to the coaching activities with players also surfaced throughout the training and game.

This study found significant agreement between the perceptions of the concepts on how coaches evaluated their coaching activities in relation to performance enhancement of players and how this support affected their development of coaching excellence. The strong relationship between recognition of self-change, refinement of coaching skills, and cultivation of players’ mind indicates that coaches direct themselves to commit to deliberate practice as a way of constructing the coaching mental model.

MOTIVATION FOR SPORT IN ITALIAN COMPETITIVE AND RECREATIONAL ADULTS

Amici, S., Capranica, L.

IUSM, Rome, Italy

Introduction

The study aimed at investigating the motivation to sport participation of Italian competitive and recreational adults in relation to gender, age and level of sport participation.

Methods

The Sport Motivation Scale questionnaire (Pelletier et al. 1995) was administered to 988 subjects (193 female and 300 male competitive swimmers, 194 female and 301 male recreational fitness participants) divided in 2 age groups (25–34 and 35–44 yrs). To test significant differences, a 2(gender) × 2(age) × 2(activity) MANOVA with seven subscales of motivation as dependent variables was applied.

Results

No significant difference emerged for gender. A main effect was found for age (Wilks’ Lambda=7.974= 4.7 <p<.05 np2=.03), with significant effects for Stimulation (F(7,974)=8.2 p<.05 np2=.01) and Amotivation (F(7,974)=11.7 p<.05 np2=.05). The 25–34 yrs showed higher values than competitive athletes. Recreational men showed higher Introjected Regulation and lower Amotivation with respect to their fitness counterpart. While women competitive showed higher Introjected Regulation than men competitive, the opposite picture was observed for fitness participants. Recreational men showed higher Amotivation than women while no difference emerged for competitive athletes.

Conclusion

According with the others study in Italian competitive and recreational adults (De Pero et al. 2003, Amici et al. 2007) gender does not represent a relevant factor to sport motivation. Independently from type of activity younger individuals showed high intrinsic motivation and low external motivation (Brustand,1988). The high Introjected Regulation of competitive women and recreational men indicate that they train to feel in good shape. Moreover, men involved in fitness feel not skilled enough for their training (Deci,1975). Finally, the higher External Regulation of recreational individuals reflects their need for external approval.

TRAINING RELATED BEHAVIOURS AND SELF-TALK DURING COMPETITION IN COMPETITIVE SWIMMERS

Stavrou, V., Galanis, E., Goltsiou, G., Voutselas, V., Hatzigeorgiadis, A.

University of Thessaly, Greece

Although athletes spend most of their time practicing in training, sport psychology research in training settings is scarce. During practice athletes face a number of physical and psychological demands, such as strenuous training and pressure to achieve optimum performance. If athletes are not able to handle these demands in the controlled environment of training, then negative feelings and cognitions might affect their competitive performance during competition. The purpose of the present study was to examine the relationships between training-related behaviours and positive and negative self-talk athletes experience during competition. Participants were 71 competitive swimmers (mean age 16.66 ± 2.75 years, mean competitive experience 7.20 ± .40). Participants completed in training the Training Related Variables Questionnaire (TRVQ; Woodman, et al., submitted), including 3 subscales (distractibility, coping with adversity, and quality of preparation). Subsequently, they completed in three occasions after the conclusion of competitions the Automatic Self-Talk Questionnaire for Sport (ASTQS; Zourbanos, et al., 2007). The questionnaire assesses 2 broad dimensions of self-talk, positive and negative, each including 4 subscales (positive: psych-up, confidence, anxiety control, and concentration; negative: worry, somatic fatigue, disengagement, and irrelevant thoughts). Cronbach’s alpha ranged from .68 to .77 for the TRVQ, and from .83 to .95 for the ASTQS.

Correlations were calculated to examine the relationships between training variables and self-talk for the three competitions. The analysis showed that (a) distractibility had low to moderate negative correlations with positive self-talk (r ranging from -.27 to -.46), and low positive correlations with negative self-talk (r ranging from .11 to .22); (b) coping with adversity and quality of preparation had low to moderate positive relationships with positive self-talk (r ranging from .35 to .36 for coping with adversity, and from .22 to .32 for quality of preparation), and low to moderate negative relationships with negative self-talk (r ranging from -.01 to -.16 for coping with adversity, and from -.14 to -.35 for quality of preparation). Overall, the results show that training habits are related to the content of self-talk during competition. The findings, in one hand stress the importance of adequate preparation and planning in training, and on the other highlight the need of further research to explore issues related to training.

PENALTY-KICK DIRECTION IN SOCCER IS INFLUENCED BY MORE THAN SIMPLY GOALKEEPER POSITION

Pepping, G.J., Dimmelendaal, M.

University of Groningen, Netherlands

Masters and colleagues (2007) showed that a goalkeeper can, by standing marginally left or right of goal centre, bias a penalty taker to kick to the side with the greater area, confirming the idea that penalty-kick direction is influenced by goalkeeper position. Based on the proposal that human decision-making is shaped by perception of affordances, including those of other people (see Mark, 2007) we hypothesised that the goalkeeper’s future action possibilities are captured by more than simply position in the goal, but that the goalkeeper’s posture in the goal captures important informational constraints for penalty kick direction.

In an experimental study we asked ten participants to view 60 slides on a touch screen monitor. In each slide, a figure of a goalkeeper was positioned on the goal line and in the centre of the goal in one of three postures: a neutral goalkeeper posture, a goalkeeper slightly leaning to the left, or a goalkeeper slightly leaning to the right. Participants indicated, as quickly and as accurately as possible, where they would shoot the penalty by simply touching the screen. Results showed an effect of posture on the direction of the penalty, F(2,18) = 403.72, p < .05, partial eta-squared = .98. In the neutral goalkeeper position participants placed 41% of the penalties to the right of the goalkeeper, and 59% of the penalties were placed to the left of the goalkeeper. In the leaning goalkeeper postures on the other hand all penalties were positioned in the direction opposite to that of the goalkeeper’s posture.

In a second experiment we manipulated both the goalkeeper’s posture and its position in the goal. We asked ten different participants to view 420 slides of the three goalkeeper postures positioned at one of seven displacements to the right or left of the centre. Again participants indicated where they would place the penalty by touching the screen. Results showed a main effect of goalkeeper posture and position on the direction of the penalty, respectively F(2,18) = 106.29, p < .05, partial eta-squared = .92, and F(6, 54) = 35.46, p < .05, partial eta-squared = .80, as well as an interaction between posture and position on the direction of the penalty, F(2,108) = 7.32, p < .05, partial eta-squared = .45.

The current study indicates that when deciding where to place a penalty kick footballers take into account more than merely a goalkeeper’s position in the goal or which side to the goalkeeper affords the greater surface area. Rather, in their judgement footballers consider the future action possibilities afforded by the goalkeeper.

PRELIMINARY VALIDATION OF THE PORTUGUESE VERSION OF THE EATING INVENTORY FOR ATHLETES

Palmeira, A., Veloso, S., Falcão, M., Dosil, J.

University Lusófona de Humanidades e Tecnologias and University of Vigo, Portugal

Purpose: The aim of present study was the preliminary validation of the Portuguese version of the Cuestionario de Hábitos Alimentarios del Deportista (CHAD), a Spanish language inventory to measure athletes’ eating behaviors.

Methods: The sample gathered 150 subjects (age M=21.1; SD=5.1 y; 88 females) from different competitive sports (although 70% were gymnasts). The CHAD is composed by 34 items evaluated with a 6 point Likert scale (1- Completely Disagree to 6 - Completely Agree). The original version measures 5 dimensions and was elaborated by Dosil and Dias (2006). The Social Physique Anxiety Scale (Hart et al, 1989), PRELIMINARY VALIDATION OF THE PORTUGUESE VERSION OF THE EATING INVENTORY FOR ATHLETES

Thursday, July 10th, 2008

14:15 - 15:15
Body Image Assessment (Williamson et al, 1989), for females the Drive for Thinness subscale of the Eating Disorders Inventory - 2 (Garner et al, 1991) and for males the Drive for Muscularity Scale (McReary & Sasse, 2000) were also used to gather data for the concurrent validation. In addition the assessment battery included demographic and body status self-reported items. The harmonization method was the translation-retrospection supervised by a three-member jury. Factor analysis, internal consistency, correlations with additional body image constructs and comparative tests between genders were calculated.

Results: We forced the 5 factor structure of the original instrument and obtained a solution with 65.7% explained variance. The dimensions replicated the original factor structure with the following dimensions: i) Weight Gain Anxiety (e.g. If I eat too much I regret it afterwards; 12 items, alpha Cronbach=.92); ii) Body Image Worries (e.g., I'm always thinking about my body; 6 items, alpha=.87); iii) Irritability (e.g., If the coach speaks about weight matters, I feel anxious; 7 items, alpha=.92); iv) Satisfaction/Dissatisfaction with Body Image (e.g., I'm satisfied with my appearance, 5 items, alpha=.79); and v) Dieting (e.g., When the season ends, I keep practicing so that I don't gain weight, 4 items, alpha=.84). These dimensions were positively correlated with the SPAS score (.23<r<.53, p<.005), BSD (.25<r<.46, p<.002), Drive for Thinness (.35<r<.51, p<.001), whilst no correlations with the drive for muscularity were found. Women scored higher in all dimensions of the CHAD (p<.05) with the exception of Satisfaction/Dissatisfaction with Body Image, where no differences were observed. The SPAS and BSD scores were also higher among women when compared to the men athletes (p<.001).

Conclusion: The results show that the preliminary version of the Portuguese CHAD is psychometrically sound, both in construct and concurrent validity. Further analysis should be conducted with confirmatory factor analysis and test-retest procedures. This measure presented a promising tool for screening eating habits among athletes that should help the detection of athletes' maladjustments toward their eating behavior and body image.

VALIDATION AND TRANS-CULTURAL ADAPTATION OF THE CHILDREN'S ATTRACTION TO PHYSICAL ACTIVITY (CAPA) SCALE IN ADOLESCENTS

Ries, F., Romero Granados, S.

University of Seville, Spain

Objectives: The purpose of this study was to adapt and validate the Spanish, German and French translation of the short CAPA scale (Brustad, 1998), in order to facilitate and expand the use of the instrument, so far only available in English and Latin American Spanish.

Background: The original CAPA scale (Brustad, 1993) consists of 25 items and was developed to measure children's interest in and attraction to, physical activity and specifically, to assess their emotional response to anticipated physical activity. Later, Brustad (1998) derived a 15-item scale from the 5 original CAPA subscales (peer acceptance, physical exertion, games and sports, liking of exercise, and the importance of exercise), retaining the 3 best items from each of the subscales and documenting better validity and reliability (alpha = .85-.95). All items were scored in both versions on a 4-point response format using Harter's (1982) structured alternative approach.

Methods: A total of 368 students (14-17 years) from Luxembourg (N=168, fluent in German and French) and Spain (N=200) were recruited into a pilot study in order to check the item comprehension of the translated 15-item CAPA scale and evaluate the psychometric characteristics in each language. In a second study, a sample of 950 students from both countries responded on an adapted version of the same scale.

Results: Using Harter's structured alternative format, internal consistency coefficients did not support strong reliability across the 5 subscales (alpha = .34-.59; overall alpha = .58). A rephrased and restructured 15-item scale increased the Cronbach alpha coefficient up to .94. Correlations among the subscales confirmed the scale's construct validity.

Conclusions: The findings through the psychometric characteristics support the use of the adapted version of the short CAPA scale in Spanish, German and French for assessing adolescents' attraction to physical activity.

EFFECTS OF HYPEROXIC INHALATION ON ENDOCRINE PARAMETERS ASSOCIATED WITH PSYCHOLOGICAL STRESS

Kawada, S., Kobayashi, K., Ohtani, M., Fukusaki, C.
The University of Tokyo, Japan

Background: Psychological stress activates the hypothalamic-pituitary-adrenal (HPA) axis and the sympathetic-adrenal-medullary (SAM) system (1,2). Salivary cortisol (s-cortisol) as a biomarker of the HPA axis, and salivary α-amyrase (s-α-amylase) and chromogranin [s-chromogranin A] as biomarkers of the SAM system have been examined in previous psychophysiological studies. Hyperoxia increases parasympathetic activity (3), indicating that exposure to hyperoxia regulates the SAM system. Therefore, we hypothesized that hyperoxic inhalation regulates the SAM system leading to a suppressed sympathetic activity, including a decrease in s-α-amylase activity and s-chromogranin A concentration. In this study, we investigated the effects of hyperoxic inhalation on the secretion status of psychological stress-induced biomarkers (s-cortisol, s-α-amylase, and s-chromogranin A). Methods: Eight healthy young males (22-24 years) performed a simple mathematical calculation (15 minutes × 2 sets, with a 5-minute interval between the sets). After the task, the subjects inspired either normal air (NA trial) or 100% O2 (hyperoxia; HO trial) for 30 minutes. Salivary samples were collected before (baseline) and after (post-point) the task, and after inspiration of normal air or 100% O2 for 30 minutes (post-30). As control, the subjects remained sat for 65 minutes and inspired normal air without the calculation task, and salivary samples were collected at the same points as the experimental trials. Results: The task caused a tendency to increase in s-cortisol and s-chromogranin A concentrations and s-α-amylase activity at post-point compared with the control. At post-30, s-cortisol concentration did not decrease to the baseline level both with and without hyperoxic inhalation. Salivary chromogranin A decreased to the baseline level at post-30 with and without hyperoxic inhalation. At post-30, s-α-amylase activity in the HO trial decreased to the baseline level. However its activity remained high in the NA trial and the level was significantly higher than that in the HO and control trials. Although the secretion of s-α-amylase and s-chromogranin A showed a tendency to increase after the task, their individual levels did not correlate with each other. Conclusions: These results suggest that hyper-
FOOT TYPE AND ANKLE SPRAIN IN VOLLEYBALL PLAYERS, WHAT RELATIONSHIP? A CASE-CONTROL STUDY

Carvalho, J.

none, Portugal

Ankle injuries are frequent in volleyball players. They might be related to several factors, such as the foot type.

Aims: Determine the prevalence of the foot type and ankle sprains by the foot type, evaluate the functional instability of ankles after sprains according to foot type, observe the changes of foot morphology after the sprain.

Methods: Transversal retrospective case-control study. The sample contain 110 individuals (55 controls IC and 55 cases IC, volleyball players) with a unilateral sprain history. The Viladot classification was used to provide the foot morphology classification using a mirror box, Functional instability was accessed using "Ankle joint Functional Assessment Tool". Results: There weren't differences on foot type between the two groups IC: normal feet (NF) = 44.5%, planus feet (PF) = 14.6%, cavus feet (CF) = 29.1%, CA: NF = 41.8%, PF = 7.3%, CF = 42.7%, p = 0.21). There was a correlation between foot type and ankle sprain, in C sample IC: NF = 47.3%, PF = 18%, CF = 34.5%, CF = 7.018, p = 0.03); no correlation was observed between foot type and functional instability, in both samples, but the sprains of the CA had more instability (C = 22.7 + 3.7, CA = 20.8 + 3.7, p = 0.004). In both samples the majority of the feet were similar to the contra-lateral (C = 72.7%, CA = 63.6%), however, we found a statistically significant difference in group C (injured foot was more planus than not injured foot, C = 25.5%, p = 0.001).

Conclusion: Didn't exist correlation between practice of volleyball and foot morphology. There is a correlation between foot type and sprains on general population, which is not observed in volleyball. Athlete's sprains were more instable, but didn't exist correlation between foot type and functional instability. In Controls injured feet were different from not injured feet, this wasn't observed on athletes sample.
**LOW-VOLUME GRIP EXERCISE TRAINING PREVENTS IMMOBILIZATION-INDUCED DECREASE IN PEAK BLOOD FLOW DURING EXHAUSTIVE GRIP EXERCISE**

Department of Sports Medicine and Science, Japan

**PURPOSE:** To determine whether strength and endurance exercise training once or twice weekly during upper limb immobilization (IMM) preserves muscle blood flow response.

**METHODS:** Sixteen male volunteers participated in the experiment after having been approved by the institutional ethical committee and obtained a written informed consent. They were divided into three groups (Immobilization, IMM-G (n=5); IMM with endurance and strength training IMM+TR1/w of once weekly, IMM+TR1/w-G (n=5); and IMM with endurance and strength training IMM+TR2/w of twice weekly, IMM+TR2/w-G (n=6)). Strength training consisted of intermittent isometric (2 sec on /2 sec off) contractions (70% of maximum voluntary contraction (MVC), 10 times), whilst endurance exercise (EEx) training consisted of contractions with one repetition per 1 sec. at 30% MVC. Non-dominant arm was immobilized with a cast for 3 weeks. Exercise training was performed during IMM once or twice a week. EEx test and MVC measurement were performed before and after IMM. The blood velocity and vessel diameter (D) of the brachial artery were measured using ultrasound Doppler and B-mode methods at rest and immediately after EEx test. Blood flow (BF) was calculated from the blood velocity and D. Changes in BF (ΔBF) were calculated by subtracting resting BF from BF immediately after EEx test.

**RESULTS:** The IMM+TR1/w and IMM+TR2/w were effective for preventing the decrease in MVC (IMM-G: 40 kgw, on average, for pre, 32 kgw for post, IMM+TR1/w-G: 40 kgw for pre, 37 kgw for post, IMM+TR2/w-G: 42 kgw for pre, 44 kgw for post). The IMM+TR1/w and IMM+TR2/w were not effective for preventing the decrease in endurance performance IMM-G: 66 sec for pre, 58 sec for post, IMM+TR1/w-G: 49 sec for pre, 53 sec for post, IMM+TR2/w-G: 54 sec for pre, 66 sec for post). Resting D did not show any significant change pre- and post-IMM for three groups IMM-G: 3.7 mm for pre, 3.39 mm for post, IMM+TR1/w-G: 3.98 mm for pre, 3.94 mm for post, IMM+TR2/w-G: 4.02 mm for pre, 4.09 mm for post). Resting BF did not show any significant change pre- and post-IMM for three groups IMM-G: 73 ml/min for pre, 71 ml/min for post, IMM+TR1/w-G: 83 ml/min for pre, 74 ml/min for post, IMM+TR2/w-G: 89 ml/min for pre, 119 ml/min for post). The IMM+TR2/w was effective for the decrease in ΔBF immediately after EEx test, but IMM+TR1/w was not effective IMM-G: 466 ml/min for pre, 279 ml/min for post, IMM+TR1/w-G: 326 ml/min for pre, 263 ml/min for post, IMM+TR2/w-G: 309 ml/min for pre, 495 ml/min for post).

**CONCLUSION:** Low-volume grip exercise training once weekly during IMM periods was not effective in preserving peak muscle BF, but the training twice weekly was effective.

**THE THERAPEUTIC ROLE OF VOLUNTARY EXERCISE AFTER FLUID PERCUSSION INJURY**

Szabo, Z., Ying, Z., Wu, A., Rada, Z., Gomez-Pinilla, F.

Semmelweis University, Hungary

Brain trauma is associated with long-term effects on cognitive function, which likely reside on the acute events after the onset of the injury such as changes in synaptic plasticity. We designed a study to test the hypothesis that voluntary exercise promotes the recovery after fluid percussion injury (FPI). 28 Sprague Dawley adult male rats were divided into 4 groups (sedinentary-sham, sedentary-FPI, exercise sham, exercise-FPI) to test the validity of our hypothesis. FPI was induced to caudal cortex, which was removed for biochemical assays, including the measurement of proteasome activity and the protein contents of the 20S alpha subunit of proteasome complex, early gene Zif 268, Synapsin I and the level of carbonyl groups. We found that FPI resulted in an increase in proteasome activity which suggests the involvement of protein degrading system in recovery of protein damage induced by FPI. The content of 20S subunit of the proteasome and the activity of the complex changed with parallel fashion indicating that proteasome complex remained relatively intact during injury. The early gene Zif 268, suggested to regulate the specific activity of proteasome, and indeed the activity change of proteasome followed the changes that were measured in Zif 268 content. This underlines the possible regulatory role of Zif 268 on proteasome during traumatic brain injury. Exercise facilitated the recovery of damaged proteins from injured brain since the carbonyl concentration decreased significantly in those rats which could do exercise after FPI. This could be an important mean since increased carbonyl level has a deteriorating effect on brain function. Synapsin I plays a vital role in synaptic plasticity, and our data revealed that exercise significantly attenuated the FPI-associated decrease in Synapsin I content.

The data of the present study suggest that the early gene Zif268 regulated proteasome pathway play an important role in the recovery process of FPI induced brain damage. Our results revealed that voluntary mild exercise could be a therapeutic tool after traumatic brain injury.

**COMPARATIVE ANALYSIS OF MUSCLE STRENGTH IN 13-14-YEAR OLD HUNGARIAN STUDENTS**

Muranyi, E., Ramocsa, G., Hamar, P.

Semmelweis University of Physical Education and Sport Sciences, Hungary

Nowadays more and more harms are threatening our health, as a result of changing lifestyle. It is true mainly for children. Nutrition (malnutrition or obesity, inactive lifestyle) has such consequences the effects of which can be perceived in the changes of body build (morphology), or in the drastic changes of spending leisure time. The initial body carriage problems (loose/incorrect carriage), are being followed by the statement of the differences between the variables when the Sign-probe was used as a statistical procedure. Beside that the calculation of percentage was applied to state the correct execution. As a summary of our results it can be stated that half of the students were able to execute those tests successfully which examined the static strength. A similar result was...
obtained when the dynamic variables were calculated. It proved the supposition that if a divergence, a dysfunction can be obtained in the static of the students, and then it can be observed in the dynamics as well. Hungarian PE special literature examines mainly the dynamics and not enough attention is paid to the static. It means that a harmony would have to be found between the static and dynamic exercises, and the tests investigating dynamic and static muscle strength, because only this way can a true picture be obtained about the functional activity of a child.

**INTRA AND INTER-EXAMINER RELIABILITY OF PECTORALIS MINOR RESTING LENGTH MEASUREMENT, USING THE PALPATION METER**

Carneiro, R., Carvalho, L., Azevedo, D., Andrade, G.

Universidade Federal de Minas Gerais, Pontifícia Universidade Católica de Minas Gerais, Brazil

**INTRODUCTION:** Shortening of the pectoralis minor reduces the posterior tilt and increases medial rotation of the scapula during arm elevation [1]. This has been described as the same kinematics patterns of individuals with impingement syndrome symptoms [2,3]. Objective: To evaluate the intra and inter-examiner reliability of pectoralis minor resting length measurement, using the Palpation meter device.

**MATERIALS AND METHODS:** Subjects: 9 males and 10 females, age range 20.8 ± 1.8, without any complaints or shoulder pain history. Materials: Palpation meter (measurement device) and a screen cover. Procedures: Subjects were asked to relax their shoulders, arms and neck while in standing position. Anatomical references for the attachments of the pectoralis minor muscle were marked [1], and then the pectoralis minor resting length was measured using the Palm device. The collection of the data was made by a second researcher, responsible for uncovering the screen and noting down the data, with the objective of blinding the evaluator. Measurements were taken in three days, with a 48 hours interval between assessments. The first and second test days were conducted by the main evaluator and both measurements were compared to obtain the intra-examiner reliability. The third day was conducted by the second evaluator and data was compared to the second measurement of the first evaluator to obtain the inter-examiner reliability. Data Analysis: An intra-class correlation coefficient test was used. Values of the first and second test days were compared for intra-examiner reliability and values of the second and third test days were compared for inter-examiner reliability.

**RESULTS:** Intra-examiner reliability of the test was .88 (p<0.05) and inter-examiner reliability was .85 (p<0.05).

**CONCLUSION:** Pectoralis minor resting length measurements using the Palpation meter device and this methodology, presents good inter and intra-examiner reliability.

**EXERCISING METHODS FOR FEMALE-STUDENTS WITH VARIOUS FORMS OF VEGETATIVE DYSFUNCTION**

Shklarenko, A., Kovalenko, T., Ulyanov, D.

Volgograd State University, The Slavonic-on-the Kuban State Teacher Training University, Russia

**Introduction.**

The students are a particular social group exposed to numerous harmful health effects due to a specific lifestyle. On entering a university an individual changes his/her social status and behavior, mentality and pattern of study. A student has to strain him/herself both physically and emotionally and needs a lot of stamina, especially in the first years of study. Our research aimed to theoretically prove and work out a differentiated approach to PT-classes for female students with health problems depending on the type of vegetative dysfunction and their physical endurance.

We stated the following research problems:

1. To define the profile of vegetative regulation, cardiovascular fitness and hemodynamics of students with poor health;
2. To practice our method.

**Material and Methods.**

During our research we used the following materials and methods: theoretical analysis and summarizing of scholarly works; cardio-rhythmography; endurance test; anthropomorphic measurements; measurements of blood pressure, circulatory dimensions, monitoring, educational experiment; methods of mathematical statistics.

The subject of our research is the physical education of students of special medical groups in higher education establishments. The research was carried out from 2004 to 2007.

**Results and Discussion.**

Our research has shown up different types of vegetative regulation among women-students: 52.7% have the sympathetic type, 24.5% have the parasympathetic type, and 22.8% have the balanced type of higher nervous activity regulation. These data allowed us to divide the women-students into the groups and to regulate the level of physical activity during the university PT-classes. The students were treated individually, it means that physical endurance and type of vegetative dysfunction of the students were taken into consideration. The work-out for women-students with sympathetic type included steady running in the aerobic regime combined with dynamic exercises. Women-students with parasympathetic type felt better after interval running in the aerobic regime combined with statodynamic exercises. The work-out for women-students with balanced type needs more detailed approach to means and methods of physical education.

**Conclusions.**

The introduction of our method in PT-classes for women-students with health problems allowed us to optimize the processes of vegetative regulation and improve their physical endurance. The number of female-students with low physical endurance decreased from 70% to 10.1%, the number of students with high physical endurance increased from 9.1% to 47.3%.
PHYSICAL REHABILITATION OF YOUNG SPORTSMEN WITH LOCOMOTOR APPARATUS DISORDER

Kovalenko, T., Sklarenko, A., Ulyanov, D.
Volgograd State University, The Slavonic-on-the-Kuban State Teacher Training University, Russia

Introduction.
The problem of children locomotor apparatus disorder is topical all over the world, what’s why the World Health Organization considers diseases of musculoskeletal system as the priority scientific research in the years 2000-2010. Recently osteopathy, desmopathy and soft tissue involvement have become more common among the children who go in for sports. The opinion that our locomotor apparatus was strengthened through exercising used to be commonly accepted but it has been disproved by a number of specialists. Functional deterioration of locomotor apparatus among sportmen can lead to orthopedic trauma and structural diseases of muscles, tendons and viscera internals.

Our research aimed to develop and scientifically prove the physical rehabilitation program for young sportmen with locomotor apparatus disorders.

The topics under discussion are:
1. Locomotor apparatus fitness of 8-12 year-old sportmen doing different sports;
2. The positive effect of our rehabilitation program on the morphofunctional state of locomotor apparatus.

Materials and methods.
The research was carried out for 3 years (2004-2006). There were two hundred and fifty-five 8-12 year-old participants with locomotor apparatus disorders, the residents of Krasnodar Territory.

For making a diagnosis we used the following methods: visual examination, palpation, somatometry and if it was needed X-ray study and ultrasonic investigation.

Results.
A medical rehabilitation program for LAD treatment has been worked out for experimental group of children. This program includes diagnostic monitoring, intensive correction system, stabilization, effect potentiation system, and preventive control.

The intensive correction system of LA disorders including synergetic reflexotherapy and individual therapeutic exercises was proved to be more effective in comparison with therapeutic exercises designed on the basis of the traditional methods of LAD treatment. The vital signs of amelioration are motility of dorsal spine and exercise tolerance of back and abdominal muscles. The gain of LA morphofunctional characteristic in the experimental group of 8-12 year-old children was more significant and speedy than in the control group.

Conclusions.
1. Locomotor apparatus disorders among young sportmen have increased recently. Diagnostics and rehabilitation of young sportmen is one of the major problems of sports medicine.
2. The research proves that the intense LAD rehabilitation program of sportmen is more effective than the traditional corrigent curative gymnastics.

RELATION BETWEEN FORCED VITAL CAPACITY AND THE LEVEL IN SPINAL CORD INJURIES

Piai, F., Gorla, J., Duarte, E., Montagner, P.
State University of Campinas - UNICAMP, Brazil

In spinal cord lesions, the conductivity of the signals through the spinal cord is harmed and, therefore, it compromises the nerved muscle. This causes a deficiency in the respiratory system, which can acquire a restrictive disorder since both the inspiratory and expiratory muscles become compromised as a function of the level and the type of the lesion. This paper aimed to establish a scale which, based solely on the information about the individual’s lesion height, enables one to determine the approximate value of the reduction of the Forced Vital Capacity (FVC), i.e. to know what the percentage of expected reduction in the lung volume is for the harmed individual with respect to the non-harmed individual. The research was conducted on a group of 23 subjects with spinal cord lesion, being 22 male and one female, with average age of 28.5 years (ranging from 20-49 years), sport practicers and non-practicers, without compromised lungs nor pneumonia or recent lung diseases. All subjects were able of performing the tasks required for the examination. The evaluated subjects were divided as follows: Group A, high cervical lesion (C3-C5), 3 participants (13%). Group B, low cervical lesion (C6-C8), 3 participants (13%). Group C, high thoracic lesion (T1-T6), 8 participants (34.8%). Group D, low thoracic lesion (T6-T12), 8 participants (34.8%). Group E, sacral and lumbar lesion (L1-5S), 1 participant (4.4%). In the research, a portable Micro Medical spirometer was used, model Microlab 3500, together with the software Spida V v 4.1, operated by the researcher who is a technician in spirometry, a title which was conceded by the Brazilian Society of Pulmonology and Tisology (SBPT). The exams were analysed by a pulmonologist entitled by the SBPT. Data was gathered only once via the spirometer, according to the norms of the American Thoracic Society (ATS) (1987), after three trials and the highest FVC value was used for the study, according to the reference values by Knudson et al (1983). Within Group A, the average FVC value with respect to the predicted values was 48.3% (ranging from 47-50%). Within Group B, the observed average value was 64.6% (52-80%).Within the subjects of Group C, the average FVC was 75.6% (63-90%) and, at last, within Group D, the average was found at 77% (67-86%). The obtained results showed a direct relation between the reduction in the lung volume for the harmed individual with respect to the non-harmed individual, even with a standard average reduction for each harmed segment. However, within each evaluated segment, there was high amplitude in the obtained values among the participants, suggesting that individual factors, such as anatomical variations in the respiratory system and differences in lesion shape, degree and intensity, yield different ventilation alterations. Moreover, these results also suggest that an individual analysis of each patient is necessary when one wants to determine the spirometric values.
INJURIES ON AMATEUR PRACTITIONERS OF BODYBOARD EPIDEMIOLOGICAL STUDY

Tavares, I., Oliveira, R.
Faculty of Human Kinetics, Portugal

Introduction.
Bodyboard is extremely difficult to evaluate, due to the environment where it takes place. This environment is influenced by a series of factors (the action of the winds, the sea streams, the type of sea and the gravitational action of the moon over the tides). These are all factors that the athlete is exposed to, and determine the conditions in which the practise of this modality occurs.

Purpose.
The main objective was to determine the semi-annual prevalence (Nov/06 - Apr/07) of injuries in amateur bodyboarders and to characterize the pattern of it’s occurrence (distribution by anatomic region and severity; frequency by gender, age, expertise level; the impact of the injuries on the activity and their evolution) for analyse potential associated factors of risk.

Methods.
A cross-sectional, descriptive and retrospective survey, by means of a validated and pre-tested self-completing questionnaire information was collected on the bodyboarder characterization, bodyboard activity and occurrence of injuries. 115 questionnaires were distributed on the beaches where bodyboard is more frequent and we collected 110 full answers (approbation: 96.5%).

Results.
The sample was formed mainly by male bodyboarders (71.8%) males and 28.2% females). The average age was 23.06 ± 5.68 years (12-50 yrs). The largest percentage of athletes (54.55%) had between 19 and 25 years, it is a predominantly young-adult sample. During the 6 months under review, were about 91 injuries. The lower limb was the corporal segment more injured, (37.9%), however, the head was the anatomic region more injured (17.2%). All the injuries occurred during the sessions (100%). Insufficient corporeal heating was the most mentioned cause of injury (48.2%). Expert athletes present an injury risk about 3.26 times greater (OR=3.259; CI=1.423-7461), than beginning or intermediate athletes.

Discussion.
Bodyboard has become an aquatic sport with a demanding increasing level, at the level of development of maneuvers and specific gestures, implying a higher performance and dedication by the bodyboarder. The practice of bodyboard may involve some risks that we need to understand for implementation preventive strategies.

Conclusion.
At least 1 of every 2 bodyboarders on the Portuguese beaches suffered an injury in a 6 months period. The analysis of associated risk factors is important for promote prevention strategies.

EFFECT OF HIGH VERSUS LOW-INTENSITY RESISTANCE TRAINING ON POST-EXERCISE HYPOTENSION IN MALE ATHLETES

Rahimi, R., Sadeghi Boroujerdi, S.
Islamic Azad University of Mahabad, Iran

The purpose of this study was to compare the effects of High versus Low-intensity weight training (HIWT versus LIWT). 85 versus 42.5 % 1RM, respectively, with same lifted load in each session, on the postexercise systolic and diastolic blood pressure response. Ten male bodybuilders with previous experience in WT were evaluated during three non-following days in bench press, biceps curl, military press, and leg press. On the first day, one repetition maximum (1RM) was determined for each exercise, and then 85% and 42.5 % of 1RM respectively were selected as used load in these exercises. On the second day, four sets × six repetitions of each exercise with 85% of 1RM (HIWT) were performed. On the last day, four sets × twelve repetitions of each exercise with 42.5% of 1RM (LIWT) were performed. Rest interval period between the sets and exercises was two-minutes in all sessions. Systolic blood pressure (SBP) and diastolic blood pressure (DBP) were determined before and up to 60 minutes postexercise. Two-way analysis of variance (ANOVA) with repeated measures was used followed by the Scheffe’s post hoc test (P<0.05) to compare SBP and DBP between and within groups. HIWT induced significant reductions in postexercise SBP during all measures, while after LIWT program significant reductions showed only in the 20 and 30 minute. HIWT program lead to significant decreases in DBP in 10 , 20 , and 30 -min, but LIWT program elicited a significant reduction only in 30 -min. It can be concluded that WT program can reduce SBP in postexercise, and it seems the higher load is necessary for that effect to occur. Also WT program with higher load seems to have more effects on SBP than DBP.

SODIUM AND FLUID REPLACEMENT DURING PROLONGED EXERCISE IN THE HEAT MAY BE BENEFICIAL IN PREVENTING THE APPEARANCE OF EXCISE ASSOCIATED MUSCLE CRAMPS

Arnaoutis, G., Giovari, A., Kollia, M., Anastasiou, C., Sidossis, L., Kavouras, S.
Harokopio University, Greece

The aetiology of exercise associated muscle cramps (EAMCs), defined as ‘painful, spasmodic and involuntary contractions of skeletal muscle during or immediately after physical exercise’ has not been clarified.

PURPOSE: To investigate the effects of sodium containing sports drinks consumed during prolonged exercise in the heat (30°C), as a response to the environmental, electrolyte and dehydration theories of EAMCs.

METHODS: Thirteen physically active but not trained males (age 24.5±3.1 yr, height 1.78±0.08 m, weight 77.9±10.4 kg) completed a 3-hour exercise protocol (consisting from 30 min intervals of walking and cycling), a set of calf raises(8x30 repetitions) and 45 min of steep, brisk walking (5.5 km/h, 12% grade), while consuming one of the experimental drinks: HNa (carbohydrate-electrolyte drink containing 36.2 mmol/L sodium); LNa (carbohydrate-electrolyte drink containing 19.9 mmol/L sodium); Wat (mineral water containing <0.3 mmol/L sodium) and Plac (placebo of distilled water with a non caloric and Na containing colour and flavour). The experimental drinks were administered every 30 minutes in the first phase and every 15 min in the third phase to balance fluid losses due to sweating.
RESULTS: HNa and LNa prevented mild hyponatremia (serum sodium below 135 mmol/L) that was observed during Wat and Plac. Plasma volume decline was fully prevented during HNa and LNa, while in Wat and Plac trials a reduction of approximately 2% was observed. None of the volunteers experienced muscle cramping, although four of them reported pre-cramping signs, like muscle stiffness, muscle twitching and irritating pain on the gastrocnemius muscle. Furthermore, three out of these four subjects developed these signs during either the Plac or Wat trial, while the fourth subject developed the same signs during the LNa trial.

CONCLUSIONS: Data suggest that low levels of sodium in the blood may cause pre-cramping signs and eventually lead to the appearance of exercise-induced muscle cramps, during prolonged exercise in the heat.

SHORT-TERM IMMOBILIZATION AND RECOVERY AFFECT SKELETAL MUSCLE BUT NOT COLLAGEN TISSUE TURNOVER IN HUMANS

Christensen, B., Dyrbørg, E., Aagaard, P., Kjaer, M., Langberg, H.
Institute of sports medicine, Denmark

Not much is known about the effects of immobilization and subsequent recovery on tendon connective tissue. The aim of the present study was to analyse the effect of a 2 week period of immobilization and a recovery period of the same length, on the turnover of tendon connective tissue. The microdialysis technique was used for this purpose. Muscle CSA and strength was measured in order to evaluate the design of the study. The cross sectional area (CSA) of m. triceps surae decreased by 6% (p<0.001) and the strength in the immobilized calf muscle decreased by 9% (p<0.05) in relation to the 2 weeks of immobilization. Two weeks of recovery only resulted in an increased CSA (6%, p<0.01), whereas strength remained reduced (p>0.05). No change in Achilles tendon CSA was detected. The systemic concentrations of PINP (serum) and CTx (urine), indirect markers for collagen synthesis and degradation, respectively, were unchanged in relation to 2 weeks of immobilization and subsequent remobilization. Tendon collagen turnover, measured as the peritendinous concentrations of PINP and ICTP (an indirect marker for collagen degradation), was unchanged after the 2 weeks of immobilization. PINP increased significantly (p<0.001) in relation to 2 weeks of remobilization (ICTP not measured).

Immobilization reduced muscle size and strength, while tendon size and collagen turnover was unchanged. Recovery resulted in an increase in muscle size, however, strength was unchanged. Tendon size did not change with 2 weeks of recovery, although collagen synthesis was increased, which could indicate that the tendon experience an increased load during remobilization. Thus, 2 weeks of immobilization is long enough to induce significantly changes in muscle tissue, whereas tendon tissue seems to be more resistant to a short period of immobilization.

THE INFLUENCES OF ACUTE EXERCISE TO LEFT VENTRICULAR DIASTOLIC FUNCTION IN THE ELDERLY - A NONINVASIVE EVALUATION

Nogami, Y., Seo, Y., Ishizu, T., Nogami, J., Sato, K., Taninura, Y., Ajsaka, R.
University of Tsukuba, Japan

Background: With aging, cardiac function especially left ventricular (LV) diastolic function reduces. Furthermore, LV diastolic function tends to decline irrespective of LV systolic function in the elderly. Although attenuated response of LV systolic function to exercise in the elderly has been reported, it is not fully elucidated the influence of exercise to LV diastolic function in the elderly. The purpose of this study was to evaluate the influence of acute exercise to LV diastolic function in elderly men.

Methods: Eleven healthy elderly subjects aged 68.7±4.2 years volunteered to participate in this study. Fifteen healthy young subjects aged 26.5±2.3 years were used as a control. All subjects underwent a symptom-limited incremental exercise on a cycle ergometer using a ramp protocol. Echocardiographic evaluation was performed before exercise, immediately after exercise, and at the 15, 30, 45, 60 minutes after exercise. LV diastolic function was evaluated by using pulsed-wave Doppler echocardiographic indexes: early diastolic mitral inflow velocity (E), E deceleration time (DcT), atrial systolic mitral inflow velocity (A) and their ratio; E/A. Furthermore, early diastolic mitral annular velocity (E') was determined by tissue Doppler imaging. Repeated one-way and two-way ANOVA were used for intragroup and for intergroup comparison. A post-hoc test was done using Bonferroni.

Results: Resting systolic and diastolic blood pressures were significantly higher in the elderly subjects than young subjects (p<0.01). Inspite of normal LV ejection fraction (EF), E/A was significantly lower (p<0.01) and E/E' < 15 ml inferior to that of young subjects (p<0.01, p<0.01). The increase in heart rate (HR), the decrease in total peripheral resistance (TPR) and the increase in LVEF from baseline to after exercise were significantly smaller in the elderly subjects (p<0.01, p<0.01, p<0.01). The decrease in E/A from baseline to after exercise was significantly smaller in the elderly subjects (p<0.01). The increase in E/E' was not significant from baseline to after exercise except immediately after exercise and similar in the both groups.

Conclusion: The present study confirmed that resting LV diastolic function reduced in the elderly. The increase in LVEF with acute exercise in the elderly was smaller than the young subjects probably because increase in HR and decrease in TPR with exercise were smaller in the elderly. Although resting LV diastolic function reduced, further deterioration after acute exercise was not demonstrated in the elderly.

THE RELATIONSHIP BETWEEN MUSCLE STIFFNESS AND ELECTROMYOGRAPHIC RESPONSE OF THE QUADRICEPS MUSCLE DURING REPETITIVE MAXIMAL ISOKINETIC KNEE EXTENSION EXERCISE

Sun, G., Miyakawa, S., Kinosita, H., Shiraki, H., Takemura, M., Mukai, N.
Graduate school of comprehensive human science university of Tsukuba, Japan

The purpose of this study was to investigate changes in muscle stiffness and surface electromyography (EMG) active parameters (mean frequency, MNFHz) throughout 100 repetitive maximal isokinetic knee extension exercise. Methods: Nineteen healthy subjects performed 100 isokinetic knee extensions. EMG signal with surface electrodes were recorded from the vastus lateralis, the rectus femoris and the vastus medialis of the right thigh and peak torque (PT) were measured with biodex for each contraction. The MNF of the EMG were calculated with FFT (Fast Fourier Transform) for each contraction. Quadriceps muscle stiffness of the anterior thigh were measured with knee extended before and after contraction. Results: MNF of each muscle and the PT were decreasing respectively. The MNF of the rectus femoris showed consequently higher correlation coefficients with PT than the vastus lateralis and the vastus medialis. The muscle stiffness for each muscle after exercise increased compared with the stiffness before exercise (p<0.05). There was high correlation the stiffness and the MNF of the rectus femoris(r=0.58, p<0.05). Conclusion: The reduction of MNF and PT showed muscle fatigue during repeti-
live maximal isokinetic knee extension exercise, and there was correlation between them (IMNF and PT) and muscle stiffness. So muscle stiffness would be a land mark for muscle fatigue.

ASSOCIATION OF MUSCLE RELATED FACTOR POLYMORPHISMS AND THIGH MUSCLE CROSS-SECTIONAL AREA IN JAPANESE POSTMENOPAUSAL WOMEN

Zempo, H., Tanabe, K., Murakami, H., Iemitsu, M., Maeda, S., Kuno, S.
Graduate school of comprehensive human sciences, Japan

Background

Share of older women among the Care Needs is larger than older men, account for 70% of Care Needs in Japan. The loss of lower limb muscle mass with age is a risk factor of fall, fracture and physical frailty, often make the Care Needs. There are only a few studies the examination of the genetic factor related to muscle mass in older. However, the previous study showed to explain genetic factor affected 56% for muscle mass in middle aged and older. Therefore, it seems that the investigation of the gene that affect for muscle become profitable information for the older. Moreover, we need to consider the non genetic factor, such as physical activity and nutrition, when consider the relationships between genetic factors and muscle mass.

The primary purpose of this study was to investigate the relationships between muscle-related gene polymorphisms and thigh muscle cross-sectional area in Japanese postmenopausal women.

Methods

One hundred-nine healthy Japanese postmenopausal women (64.1±6.0 years old, 53.0±6.6 kg, BMI=23.2±2.6 kg/m^2) participated in this cross-sectional study. Thigh muscle CSA was measured using magnetic resonance image. alpha-actinin -3 (ACTN3), interleukin-15 receptor A (IL-15RA), angiotensin converting enzyme (ACE) and Akt genotype were determined using real-time PCR with DNA extracted from blood. Daily physical activity was measured using a uniaxial accelerometer for 1 week. Dietary intake was assessed by nutritionist from a continuing survey of food intake by individuals for 3 days.

Results

In ACTN3 genotype, thigh muscle CSA of subjects was significantly difference, in contrast, there were not find a association between IL-15RA, ACE and Akt genotype and thigh muscle CSA of subject. ACTN3 was classified XX (alpha-actinin-3 protein absence) genotype and RR+RX (alpha-actinin-3 presence) genotype by reference to previous study. Despite, there were not significant differences in age, height, body weight, BMI, physical activity and daily protein intake between the groups, the thigh muscle CSA of subjects was significantly smaller in the XX genotype compared with the RR+RX genotype.

Conclusion

We have demonstrated that ACTN3 polymorphism effected on thigh muscle cross-sectional area in Japanese postmenopausal women.

EFFECT OF AEROBIC IN COMBINATION WITH RESISTANCE TRAINING ON THE LEVEL OF LEPTIN FOR ELDERLY WOMEN

Tomoko, I., Shimizu, K., Sakata, Y., Kuno, S., Mesaki, N., Imagawa, S.
Graduate School of Comprehensive Human Sciences, Japan

Introduction: After menopause, the rates of death from the coronary heart disease (CHD), type 2 diabetes mellitus and lipid abnormality have been reported to increase for women. It has been reported previously that regular aerobic in combination with resistance training can improve the blood lipid profile and the body composition in healthy elderly men. Aerobic in combination with resistance training may affect to prevent the disease for elderly women.

PURPOSE: The aim of this study is to investigate the effect of aerobic in combination with resistance training on the adipocytokine, glucose and lipid metabolism in healthy elderly women.

METHOD: Fourteen elderly women (training group=8; control group=6) participated in this study (64.8 ± 4.7 age). Aerobic in combination with resistance training was performed for three times per week in the training group. Aerobic exercise was cycled on ergometers was set at 75% of the targeted heart rate for 30 minutes. Resistance exercise was selected to stress the major muscle groups in the following order (squat; leg extension; leg curls; abdominal crunches; and low back muscle). Plasma leptin, adiponectin, glucose, insulin, insulin resistance (Homeostasis Model Assessment), total-cholesterol, high-density lipoproteins cholesterol, low-density lipoproteins cholesterol, triglyceride, and body composition were measured before and after the training.

RESULT: In the training group, the levels of plasma leptin and the body fat were significantly decreased (p<0.05), and fat free mass significantly increased compared with before training (p<0.05). Those of plasma adiponectin, glucose and lipid metabolism were not changed during 8 weeks training. However, those of plasma leptin and body composition were not changed in the control group compared with before and after the training.

CONCLUSION: The level of leptin was significantly decreased without decreasing body weight. It is suggested that aerobic in combination with resistance training decrease the level of leptin by improving body composition.

EFFECTS OF PHYSICAL ACTIVITY DURING CHEMOTHERAPY TREATMENT - A LONG TERMED INVESTIGATION

J.W. Goethe-University Frankfurt/Main, Germany

Introduction.

Chemotherapy is known as standard medication in palliative cancer care. However, most patients suffer from side effects like immobility and fatigue symptoms. Physical exercise has been recognized as one effective approach to facilitate the coping process of chronic diseases. Therefore the present study tried to evaluate the effects of physical activity on aerobic capacity and quality of life during ongoing chemotherapy treatment.

Methods:

Ten patients (54 +/- 12 yo.) with histological confirmed cancer diagnosis and ongoing chemotherapy participated in this longitudinal study. Quality of life (EORTC: QLC-30) and aerobic capacity were examined before participation in individualized exercise programs. The questionnaire contains 30 items and was scored according to the manual. Scales that were used in this study included the five functional scales, the global health status quality of life scale and the nine symptom scales from the core section of the EORTC QLC-C-30. All subjects performed a graded exercise test on a calibrated cycle ergometer with 3 min stages, an initial power output of 0W and increments of 25W. Breath-by-breath ventilation and beat-to-beat heart rate were monitored by mobile devices (Oxycon Mobile, Jaeger, S810, Polar).
All standardized measurements were repeated after 1 and 3 months. Statistical analyses were conducted using SPSS. Non-parametric testing (Friedman-test) was selected to determine significant differences in cancer quality of life scales and aerobic capacity measures. In all analyses, a P-value < 0.05 was considered statistically significant.

Results:

Results show a significantly enhanced aerobic capacity (VO2max) after 4 (24.09 vs. 26.62 ml x min-1 x kg-1, p<0.01) and 16 weeks (24.09 vs. 27.37 ml x min-1 x kg-1, p<0.05) of exercise training. The analysis of the EORTC-questionnaire demonstrated significant (p<0.05) increases in social (81.6% vs. 88.4% vs. 96.6%) and physical functioning (85.3% vs. 90.6% vs. 95.3%) in relation to the pre-training status. Patients furthermore reported a significant (p<0.05) reduction (20%) of fatigue symptoms after 16 weeks of training.

Conclusions:

Cancer patients are harmed through the explicit side effects of chemotherapy treatment. Physical activity provides an opportunity to be proactive against cancer. Not only a physical enhancement results, also quality of life and social functioning improved with physical activity. Thus, moderate exercise training seems to support the coping process with chemotherapy treatment specific side effects. Currently there are increased requirements to inform patients, physicians and cooperating professionals about the exceptional advantages of physical activity even in the very early stages of cancer treatment. Health platforms, maybe via internet, should be installed to reach and inform the patient shortly after diagnosis and to encourage them, to participate in adequate physical activity right at the beginning of the cancer treatment.

CHANGES IN STRESS AND RECOVERY RELATED TO INJURY IN YOUNG ELITE SOCCER PLAYERS

Brink, M., Visscher, C., Arends, S., Lemmink, K.

University Medical Center Groningen, University of Groningen, The Netherlands

Several studies have described risk factors for injury in soccer players. Andersen and Williams developed a model that focuses on psychosocial factors (1). This model states that psychosocial factors (i.e. daily hassles) contribute to the stress response causing physiological and attentional changes (i.e. increase in muscle tone, distractibility). These changes make athletes more susceptible to injuries. In the present study it was hypothesized that injured soccer players have more stressful events and less recovery related activities.

Thirty-seven young elite soccer players (Mean ± SD. Age (years) 16.5 ± 1.2, Height (cm) 177.0 ± 7.8, Body weight (kg) 66.5 ± 8.7 Body fat (%) 8.5 ± 2.1) participated in this study. Stress, recovery and injury were monitored over one competitive season. The Dutch version of the Recovery Stress Questionnaire for athletes (RESTQ-Sport) was used monthly to assess the stress-recovery state of players (2). The RESTQ-Sport consists of twelve general and seven sport-specific stress and recovery scales. Subjects were asked to indicate how often stressful events and recovery related activities occurred during the last four weeks. The members of the medical staff recorded injuries according to recent recommendations (3). Data were analyzed using multilevel modeling, with RESTQ’s subscales as dependent variable and injury or no injury as factor.

During the study period 163 injuries were reported of which 98 were time loss injuries and 65 required medical attention. The total incidence was 19.25 injuries per 1000 playing hours. In sum, 342 RESTQ’s were completed. Injured soccer players scored higher on the injury scale (p<0.05). No significant differences were found on the other general and sport specific stress and recovery scales.

It can be concluded that, with exception of the injury scale, injured soccer players do not differ in stressful events and recovery related activities. Thus, moderate exercise training seems to support the coping process with chemotherapy treatment specific side effects. Cancer patients are harmed through the explicit side effects of chemotherapy treatment. Physical activity provides an opportunity to be proactive against cancer. Not only a physical enhancement results, also quality of life and social functioning improved with physical activity. Thus, moderate exercise training seems to support the coping process with chemotherapy treatment specific side effects.

EFFECTS OF THREE DIFFERENT WATER TEMPERATURES ON DEHYDRATION IN COMPETITIVE SWIMMERS

Macaluso, F., Di Felice, V., Boscaino, G., Bonsignore, G., Stamponi, T., Farina, F., Morici, G.

University of Palermo and Hospital “Villa Sofia - CTO”, Italy

Athletes perform trainings and races in a wide range of environmental conditions, as cold/hot ambient temperatures, high/low altitudes and high/low relative humidity. Physical activity can induce significant changes in body temperature (core and skin temperature), depending on environmental conditions, clothing/equipment, kind of sport practiced, intensity and duration of the exercise. The present study examined the effects of three different water temperatures (23, 27 and 32°C) on body temperature, fluid balance, performance, leukocyte formula, skeletal and myocardial muscle damage markers in competitive athletes swimming 5 km in an indoor swimming pool.

Nine male competitive swimmers swam 5 km with water at the temperature of 23, 27 and 32°C. Immediately before (Pre) and after (Post) each trial a sample of blood and urine were collected, body weight was recorded, rectal and skin temperature were measured. The rectal temperature absolute variation (Post-Pre) in the 23°C trial was significantly lower than in the 27 and 32°C trials, and the variations between Post and Pre skin temperature in the 23 and 27°C trials were significantly lower than the 32°C one. The Post urine volume output was not significantly different in the three trials, although the variation in urine specific gravity between Pre and Post sampling of the 23°C trial was significantly lower than in the 27 and 32°C ones. Plasma volume increased and the cellular volume decreased in all three conditions. The dehydration percentage was the highest in the 32°C and the lowest in the 23°C trial. There were no significant differences in leukocyte formula percentage and serum markers of skeletal (CPK, LDH) and myocardial (CK-MB) muscle damage in relation to water temperature. In the 27°C trial it was recorded the best chronometric time. Swimming in elevate water temperature without fluid replacement resulted in dehydration, but the 5 km swimming distance was not enough to induce a serious dehydration to impair performance in the competitive swimmers.

THE IMPACT OF L-CARNITINE INGESTION ON PHYSIOLOGICAL, MOTORIC AND SUBJECTIVE INDICATORS OF MUSCULAR REGENERATION AND CELLULAR DAMAGE

Mank, D., Hawener, I., Flacke, J., Reusch, HP., Ferrauti, A., Platen, P.
Ruhr-University Bochum, Germany

Objective: Studies on the influence of carnitine on cellular damage after strenuous eccentric exercise showed attenuated markers of cell disruption suggesting a possible beneficial influence on regeneration and cell protection. The aim of this study was to further investigate the possible influence of carnitine on parameters of cell damage and regeneration.

Methods: 10 healthy subjects (24.8 ± 1.7 yrs) participated in the study. Using a double blinded cross-over design subjects performed 2 times a protocol of 2 runs (a 10 km run plus a 10 x 400m run with 1 week in between in a randomized order). 2 weeks before and during both run protocols subjects ingested either 3 g carnitine (V) or placebo (P) per day in a randomized order with a 2-week wash out period in between. We analyzed capillary actin concentration and creatine kinase (CK) activity as indicators of muscle damage at baseline (after 2 weeks of V or P ingestion prior to any running) and 24 hrs (actin and CK) as well as 48 hrs (CK) and 72 hrs (CK) after each run. Blood lactic acid concentration (La) was measured at rest and directly after the 10 km runs, as well as 5 min after each 400 m run. Jumping performance was determined using a squat and drop jump test before, immediately after and 72 hours after each run. Muscle soreness was assessed using the Visual Analog Scale (VAS) prior to each run and on three consecutive days.

Results: La, jumping performance, and VAS values were unaffected by carnitine intake. CK was lower (p<0.05) at baseline and 24 hrs after the 10 x 400m run series in V as compared to P. No group differences for CK could be detected prior to and after the 10 km intervention. Actin was measurable at baseline in most of the subjects, however remained below the detection limit 24hrs after exercise in some subjects, showing no clear pattern.

Conclusion: The main findings of the investigation include unaffected La increments after short intensive and longer-lasting runs and no effect on jumping performance and on perceived muscle soreness by orally ingested l-carnitine. CK seemed to be slightly reduced after short intensive runs under verum, indicating a possible protective effect on the muscle cells. But as baseline values have already been attenuated under this condition, and we did not control for training loads 2 weeks prior to baseline, the underlying mechanisms are unclear. One possible explanation could be the well described vasodilatative property of l-carnitine resulting in enhanced blood flow and an attenuated activity of the purin metabolism during exercise, leading to a lower production of muscle membrane destructive metabolites. In contrast to some other studies using muscle trauma patients, actin seems not to be usable as a valid and reliable parameter for the determination of muscle damage in healthy sports men and women. Further research is required to investigate the underlying mechanisms causing a possible membrane protective effect of l-carnitine.

STRENGTH TRAINING AND THE MENSTRUAL CYCLE: A PILOT STUDY ON MUSCULAR STRENGTH, MACROSCOPIC AND MICROSCOPIC PARAMETERS

Han, A., Sung, E., Weber, S., Bloch, W., Platen, P.
Ruhr-University Bochum, Germany

Purpose: The menstrual cycle is divided into 2 main phases, the follicular and the luteal phase. Each phase is characterized by a certain profile of different hormones. Menstrual cycle specific regulation of many hormones is not clear so far. This is especially true for the interaction between estradiol, human growth hormone (hGH), and IGF-1, all of them possible anabolic hormones on the level of the muscular cell and therefore important supporting factors during strength training. We, therefore, decided to conduct a pilot study in order to investigate possible different effects of follicular phase-based (FT) versus luteal phase-based (LT) strength training on strength parameters, muscle volume and muscle cell type and diameters.

Methods: Two healthy eumenorrheic women (P1, P2) completed a strength training program for 3 menstrual cycles (approx. 12 weeks). Exercises included biceps curl, triceps press, leg extension, leg curl, calf raise and hip extension. The subjects performed FT with muscle groups of the right side of the body and LT with muscle groups of the left side of the body. FT was organized 4 times a week in the follicular phase and once a week in the luteal phase, and LT was organized 4 times a week in the luteal phase and once a week in the follicular phase. Maximum isometric force (ISOmax) and maximum dynamic force (DYNmax) were measured for each major muscle group prior to, during (5 times per cycle), and after training. Muscle diameters (DM) were measured by means of ultrasound in all respective muscle groups, and muscle fiber composition, fiber diameters and numbers of cell nuclei were analyzed in muscle biopsies from the musculus vastus lateralis of both legs, prior to and after the training program.

Results: Mean ISOmax values of all muscles increased by 29% after FT as compared to 19% after LT. Mean DYNmax values of all muscles increased by 46% after FT and by 38% after LT. Mean DM of all muscles increased by 5.3% after FT and by 3.3% after LT. Analysis of fiber composition revealed unclear results. Fiber diameter, however, showed clear trends: type II muscle fiber diameters increased more after FT as compared to LT. Values were: P1 type Ila: 53/64 um, type Iib: 39/55 um; P2 type Ila: 43/57 um, type Iib: 37/49 um; LT: P1 type Ila: 64/54 um, type Iib: 48/42 um; P2 type Ila: 62/59 um, type Iib: 47/49 um. Type I fibers showed unclear developments.

Moreover, the increase in cell nuclei numbers was higher after FT (P1: +5.4%, P2: +20%) as compared to LT (P1: -19%, P2: +6.5%).

Conclusions: A follicular phase-based strength training showed more pronounced effects on muscle strength as well as macroscopic and microscopic parameters as compared to a luteal phase-based training. This is probably due to the specific hormonal milieu during each phase of the cycle. More subjects have to be included in order to further analyze menstrual cycle specific training effects.

The study was supported by Bundesinstitut für Sportwissenschaft, Bonn (IIA1/070110/08)

REHYDRATION AFTER EXERCISE UNDER HOT ENVIRONMENT: EFFECTS OF BEER VS WATER

Facultad de Ciencias de la Actividad Física y del Deporte. Universidad Politécnica de Madrid. Spain

Introduction.
Beer is characterized for its low alcoholic content and notable amount of low molecular weight maltodextrins, amino-acids, minerals, B group vitamins, anti-oxidants, and carbohydrates. Hence, moderate intake of beer could be an alternative in the restoration of fluid balance after exercise-induced dehydration.

Aim.
To determine the effectiveness of beer intake (660 ml) in restoring fluid balance after exercise-induced dehydration compared with the effect of water intake.

Material and methods.

In a cross-over study design, sixteen healthy male volunteers (age: 21.1 ± 1.4 years, VO2max: 55.9 ± 3.6 ml min kg⁻¹) performed two randomized trials separated by a 3 weeks interval. In each trial the subjects exercised at 60% of maximum aerobic speed in hot environment during 60 minutes (35 ± 1 °C, 60 ± 1% relative humidity). After the exercise bouts, the subjects rest for 2h in a separate chamber at the same environmental conditions and were asked to drink 660 ml of beer plus water ad libitum (trial B+W), whereas in the other trial the participants were allowed to drink only water (trial W). The subjects were weighted before exercise, after exercise and after 2 h of rehydration. Additional measured variables included fat free mass (measured by dual-energy x-ray absorptiometry), percentage of change in plasma volume and thirst scale. Urine volume and fluid intake were collected during the rehydration period.

Results.

A decrease of 2.4 ± 0.3% of their body weight was observed. A decrease in fat free mass and plasma volume occurred after exercise in the heat (all p < 0.001), whereas thirst score increased significantly after exercise in both trials (all p < 0.001). During the rehydration period, there were no differences in the amount of fluid intake between trials (1660 ± 587 vs 1644 ± 620 ml in B+W and W, respectively, p = 0.09). The urine volume was also similar in both trials (281 ± 374 vs 223 ± 245 ml, in B+W and W, respectively, p = 0.70). After two hours of rehydration, the subjects recovered 1.3% and 1.6% of body weight in the B+W and W trials, respectively (p = 0.29). Fat free mass and plasma volume increased significantly after the rehydration period in both trials (fat free mass = 0.09% ± 1.5% vs 1.3% ± 12%, plasma volume = 3.3% ± 5.2% vs 5.1% ± 7.9% in B+W and W, respectively, all p < 0.001) and thirst score decreased at pre-exercise levels.

Conclusion.

The results of the present study suggest that beer could be an alternative effective post-exercise rehydration drink in healthy moderately trained young adults, even under hot environment. Thirst was not enough for stimulating voluntary drinking and recovering full body weight loss. In addition, it is important to highlight that the messages related to the benefits of moderate consumption of alcohol have always been addressed to adult populations.

THE EFFECTS OF EXERCISE INDUCED MUSCLE DAMAGE ON SENSORIMOTOR AND NEUROMUSCULAR PERFORMANCE IN MALES

Tsakiris, A., Gleeson, N., Eston, R., Minshull, C.

University of Exeter, United Kingdom

Optimal functioning of the musculature in a timely manner is paramount to the dynamic stabilisation of synovial joints. It is plausible that exercise-induced muscle damage (EIMD) might be an important determinant of the extent of injury-risk and influence performance capabilities including muscle activation patterning and sensorimotor control at the extremes of the joint’s range of motion. The aim of this study was to assess the effects of EIMD on sensorimotor and neuromuscular performance in males. Peak force, electromechanical delay, sensorimotor performance (force error relative to a ‘blinded’ target) capabilities and descriptive markers of EIMD (perceived muscle soreness, passive hip flexibility) were assessed in ten male subjects (age: 20.9 ± 2.3y; height: 1.78 ± 0.06m, body mass: 72.3 ± 7.4kg [mean ± SD]) prior to and at 0.5h, 24h, 48h, 72h following a damaging exercise protocol incorporating six sets of 10 isokinetic eccentric contractions of the ipsilateral knee flexors. Neuromuscular and sensorimotor assessments were completed at 30 degrees of knee flexion. Results showed that while performance capabilities remained constant in the control period and contralateral control leg, the EIMD intervention provoked reduced performance of the involved leg compared to pre-intervention levels in peak force (35.7%: 259.2 ± 69.8 N versus 166.7 ± 45.1 N [pre- versus post-48h], F(4,36) = 3.3, p <0.05), passive hip flexibility (22.5%: 0.268 ± 0.083 m vs. 0.205 ± 0.064 m [pre- vs. post-72h], F(4, 36) = 10.9, p <0.001), electromechanical delay (52.7%: 55.1 ± 5.2 ms vs. 84.0 ± 5.9 ms [pre-versus post-48h], F(4,36) = 6.5, p <0.01) and sensorimotor performance (5.8%: 10.3 ± 3.7% vs. 6.1 ± 5.9% [pre-versus post-24h], F(4,36) = 5.9, p <0.05). Performance capabilities had not recovered significantly 72 hours after the damaging protocol. The EIMD-related sensorimotor and neuromuscular performance deterioration was prominent for 72 hours and was sufficiently large to raise concerns about a commensurate loss of capability for rapid and dynamic stabilisation of synovial joints during episodes of threat from injury.

PHYSICAL ACTIVITY AND MENTAL HEALTH IN AN ELDERLY COHORT

Bucchi, C., Hinrichs, T., Burghaus, I., Trampisch, T., Klaaßen-Mielke, R., Endres, H., Lungenhausen, M., Platen, P.

Ruhr-University Bochum, Germany

Objective:

The aims of this study were: 1. To assess the prevalence of self-reported depressive symptoms in an elderly German cohort and 2. to investigate associations between self-reported physical activity and self-reported depressive symptoms in this cohort. Methods:

In a monitored prospective cohort study [German epidemiological trial on ankle brachial index, getABl], 6880 unselected patients >65 years were followed up by 344 representative primary care physicians in Germany since November 2001. In the 5-year follow up, 2120 patients (median age 76; 70-94 years; 53.7% women) of the cohort were interviewed about their level of physical activity (defined as activity of moderate intensity for at least 30 minutes per session; 1: no activities or active for less than once per week; 2: active for 1-3 times per week, 3: active for >3 times per week).

The 15-item geriatric depression scale (GDS-15) was used to measure self-rated depressive symptoms. The following questions of the GDS-15 have been analysed: Are you basically satisfied with your life? (GDS1), Do you feel that your life is empty? (GDS3), Are you in good spirits most of the time? (GDS5), Do you feel happy most of the time? (GDS7), Do you think it is wonderful to be alive now? (GDS11) and Do you feel full of energy? (GDS13). Every single item allows splitting the cohort into two groups: people who answered yes (1) and people who answered no (0). The Wilcoxon two-sample test was used for every item to reveal significant differences in activity level between Y and N. Only persons who answered the respective questions were included in the analyses. In all cases these were more than 95% of the patients.

Results:

57.4% of patients reported a high activity level (level 3), 23.2% an intermediate activity level (2), and 19.4% reported to be inactive (1). 94.1% of patients were basically satisfied with their lives, 8.4% felt that their life is empty, 91.7% were in good spirits most of the time, 88.6% felt happy most of the time, 91.2% thought that it is wonderful to be alive now and 80.3% felt full of energy. Significant differences in activity...
Twenty-nine basketball teams of the 1st and 2nd regional division participated in this investigation. A valid self-reported questionnaire was used to determine demographic data, sports specific injuries and potential risk factors in relation to AKP.

Methods:

The study was carried out in the context of an international hockey tournament (4 Nations Cup 2008) in Argentina. 18 elite female field hockey players (2 goalkeepers (G), 5 defenders (D), 6 midfield players (M) and 5 forwards (F)) of the German Field Hockey Women’s National Team were recruited for this study. Prior to the tournament individual maximal heart rates (HRmax) and the maximal oxygen consumption (VO2max) were measured using a treadmill run-test to exhaustion. Heart rate was monitored continuously during 4 matches of the tournament using the Polar® Team System.

Results:

VO2max for the different positions were: G: 47.07 ± 1.3 ml/kg, D: 50.1 ± 3.0 ml/kg, M: 50.5 ± 3.4 ml/kg and F: 46.4 ± 2.0 ml/kg. There was no significant difference between the positions D, M and F (p> 0.05). Even if the mean heart rate values are expressed as percentage of maximum individual heart rate, there are no differences between the positions (p> 0.05). Two-way ANOVA revealed no significant changes in mean heart rates in the progress of the tournament.

Conclusion:

The present study confirms the results of a previous investigation of heart rate profiles of the German Women’s National Team at the 4 Nations Cup 2006 (Franke et al., 2007). Field hockey is determined by high physiological demands for all field players independent of their position. A more detailed view at the physiological factors that determine position specific hockey performance is necessary to optimize tournament preparation. Especially position specific patterns in motion frequency and changes in repeated-sprint-performance over consecutive games should be observed in detail. Changes in heart rates could not be observed during the tournament as a possible measure of fatigue.

PREVALENCE AND ASSOCIATED RISK FACTORS OF ANTERIOR KNEE PAIN IN BASKETBALL PLAYERS USING A SELF-REPORTED QUESTIONNAIRE

Aerts, I., Cumps, E., Meeeusen, R.
Vrije Universiteit Brussel, Belgium

Background

Sports involving running, jump-landing maneuvers and sudden decelerations are at high risk for anterior knee pain (AKP) [1]. AKP is suggested to encompass all pain-related problems of the anterior part of the knee and is a common overuse injury in basketball [2]. Data on prevalences and associated risk factors of AKP in basketball are limited [1].

Objective

The objective is to determine point, lifetime and 1-year prevalence and associated risk factors of AKP in basketball in Flanders in both men and women.

Design

A cross-sectional study was set up.

Setting and participants

Twenty-nine basketball teams of the 1st and 2nd regional division participated in this investigation. A valid self-reported questionnaire was used to collect demographic data, sports specific injuries and potential risk factors in relation to AKP.

Methods

Eventually, 201 subjects (86 female and 115 male) participated and were asked to fill in a self-reported questionnaire. Prevalences and 95% Confidence Interval (CI) were calculated to analyse differences between divisions and gender regarding AKP. A logistic regression was used to predict the probability of occurrence of AKP given certain risk factors. The most significant independent variables identified in the univariate stage of analysis were then entered into a multivariate logistic regression equation. Odds ratios (OR) with 95% CI were reported for the multivariate analysis. Level of significance was set at 95%.

Results

The self-reported 1-year prevalence of AKP was 56%. Most common pathologies were Patellar Tendinopathy (26.8%) and Patellar Femoral Pain Syndrome (11.3%) (CI 95%).

Male basketball players were significantly more prone to AKP compared to their female counterparts and male players of the 2nd regional division significantly sustained more AKP in comparison with the 1st regional division whereas in female, the 1st regional division significantly sustained more AKP. Other factors such as age, length, BMI, gender, level of play, were not significantly related to AKP in basketball. Players who played with high-top basketball shoes were 3 times less likely to sustain AKP (OR = 0.38 [95% CI:0.18-0.85]).
Conclusion

High-top basketball shoes could have an influence on the prevention of AKP. These results are promising in the prevention of AKP in basketball players but further research on this topic is necessary.

THE EFFECTS OF PHYSICAL ACTIVITY ON VISFATIN, GHRELIN AND APELIN LEVELS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

Aristotle University of Thessaloniki, Greece; Academy of Athens, Greece

Objective-Aim: Growing evidence support the beneficial effects of physical activity on cardiovascular (CVI) system. Novel members of adipocytokines such as visfatin, ghrelin and apelin have recently emerged as CV risk factors strongly related with adverse events. The aim of this study was to determine the influence of physical activity on traditional and novel CV risk factors in patients with type 2 diabetes mellitus (T2DM).

Methods: A total of 98 individuals (30 males, 68 females) with T2DM, already receiving antidiabetic medications (metformin), but with poor glycemic control (HbA1c>6.5%) participated in this study. The mean age and the mean duration of T2DM were 61.33±5.58years and 4.92±2.6 years, respectively. All the patients were overweight (BMI>25kg/m2), without any diabetic complication and none was receiving lipid lowering treatment. Physical activity was evaluated according to the kcal/min expended and the weekly frequency of exercise, using a valid questionnaire. Physically active patients were considered those who reported non-occupational physical activity > once/week (at least 30 min/time). According to the above criteria patients were stratified as active (n=24) or sedentary (n=74). Clinical parameters: body-mass index (BMI), waist-hip ratio (WHR), blood pressure (BP) and biochemical parameters: fasting plasma glucose (FGP), Hba1c, total cholesterol, HDL, LDL, triglycerides, fasting insulin, insulin-resistance index (HOMA-IR), hsCRP, visfatin, ghrelin and apelin were determined. For statistical analysis we used Student’s independent t-test and linear regression analysis (p<0.05).

Results: Concerning anthropometrical characteristics, glycemic profile (FGP, Hba1c), lipid parameters and apelin we did not detect significant differences between active and sedentary patients (p>0.05). In comparison with sedentary group, active group showed lower levels of hsCRP (1.87±0.52mg/L vs 3.01±1.33mg/L; p=0.008), fasting insulin (10.07±4.21mU/L vs 12.99±5.18mU/L; p=0.033), HOMA-IR (5.92±3.91 vs 7.6±±3.62, p=0.038), visfatin (9.51±5.21ng/ml vs 27.4±17.4ng/ml; p<0.001) and ghrelin (8.05±3.02ng/ml vs 11.43±3.07ng/ml; p=0.033) levels. In the linear regression analysis after adjustment for age, sex and BMI the aforementioned differences between active and sedentary diabetic patients remained significant (p<0.05).

Conclusions: Physical activity suppresses inflammatory milieu, along with beneficial effects on novel CV risk factors, indicating an alternative cardioprotective mechanism in patients with T2DM.

Supported by the European Social Fund and National Resources-PYTHAGORAS II. N.P.E. Kadoglou was granted by the Alexander S. Onassis Public Benefit Foundation.

EFFECT OF POST-EXERCISE HEAT TREATMENT ON ECCENTRIC CONTRACTION-INDUCED MUSCLE DAMAGE AND MUSCLE SORENESS IN OLDER PEOPLE

Saga, N., Ogura, Y., Ichinoseki-Sekine, N., Naito, H., Katamoto, S.
Institute of Health and Sports Science & Medicine, Juntendo University, Japan

For older people, it is important to establish safe and effective strength training strategy. Recent studies suggested that heat treatment at one day before eccentric contractions could inhibit muscle damage and muscle soreness after eccentric contractions. The mechanisms are still unknown but the inhibitions might be associated with an induction of heat shock proteins. Moreover, heat treatment immediately after eccentric contractions may increase muscle blood perfusion and promote recoveries from muscle damage. The purpose of the present study was to clarify the effect of post-exercise heat treatment on eccentric contraction-induced muscle damage and muscle soreness in older people.

Sixteen untrained older male and female subjects (64 ± 4 yrs) volunteered to participate in this study. They were randomly assigned to Con (n = 8) or Post-H (n = 8) group and were asked to perform 30 repetitions of maximal isokinetic eccentric contractions (ECC, 10 reps x 3 sets) of non-dominant elbow flexors at angular velocity of 30 °s-1 by means of isokinetic dynamometer. Immediately after ECC, the Post-H group underwent a microwave hyperthermia treatment (150 W, 20 min) to the same arm. Muscle soreness, serum creatine kinase activity, serum insulin-like growth factor-1 concentration, range of motion of elbow joint, upper arm circumference and maximal isometric strength were assessed for 4 days after ECC. As the results, the range of motion of elbow joint of Post-H group was significantly greater than that of Con group (P < 0.05), although there were no differences in the other markers of muscle damage and soreness between Con and Post-H group. These results suggest that a heat treatment immediately after ECC on skeletal muscles could be effective to suppress an increase of muscle stiffness after ECC in older people.

ROLE OF PHANTOM AND T2C IN TEAM SPORTS

Massuça, L., Fragoso, I., Barrigas, C.
Faculty of Human Kinetics, Technical University of Lisbon, Portugal

Every now and then the Lentiini Combined Method has been used instead of the original Phantom Method to study the sportmen proportionality. Therefore the aim of the present study was (1) to compare these two methods; (2) to test the Lentiini Combined Method in 34 (N) male handball players, aged 23.65 ± 4.76 years, of two different teams participating in the Portuguese Professional Handball League. The anthropometric measures were taken in accordance to ISAK as described in Fragoso & Vieira (2005). by a group of anthropometrists accredited by ISAK (International Society of the advance of Kinanthropometry). Microsoft Office Exel 2007 and SPSS 15.0 for Windows were used to analyze the anthropometric data. The statistic methods used were descriptive statistic, T-student test, ANOVA one-way and a post-hoc test (LSD). The results showed: (1) the Lentiini Combined Method normalized the data pulling the results closer to the mean Z ratio.
values; (2) the proportionality constant of 170.18 of the Phantom Model emphasizes the heterogeneity of the samples when height is a competitive advantage; (3) allows similar statistical results; (4) the use of the present technique reduces the complexity of the proportional calculations.

RESISTANCE TRAINING IN THE TREATMENT OF THE METABOLIC SYNDROME: A META-ANALYSIS
Strasser, B., Schobersberger, W.
University of Health and Life Sciences, Austria

Background: Aerobic endurance training is generally recommended for people with diabetes mellitus type 2 (T2DM). Resistance training (RT) has been shown to improve muscle strength in both healthy elderly individuals and individuals with chronic disease and improve insulin-stimulated glucose uptake in patients with impaired glucose tolerance or manifest T2DM. Objectives: The purpose of this systematic review is to evaluate randomized controlled trial (RCT) data on the effects of RT on the metabolic clustering in patients with abnormal glucose metabolism. Search strategy: 13 RCTs were identified through MEDLINE and EMBASE from January 1990 to December 2006. Selection criteria: We included all RCTs comparing RT with a control group in patients with abnormal glucose regulation. Data analysis: Weight mean differences between the post-intervention values of the intervention and control groups were used to analyze the size of the intervention effects. All data were analyzed with a software program (Review Manager 4.2.10) of the Cochrane Collaboration. Main results: Glycated hemoglobin was reduced by 0.5% HbA1c with RT I:0.5%. HbA1c WMD, 95% confidence interval (CI) -0.59 to -0.43. This is both clinically and statistically significant (P < 0.00001). Fat mass was reduced statistically significant by 3.0 kg with RT I:3.04 kg WMD, 95% Cl -3.73 to -2.35, P < 0.000001). A RT intervention resulted in a significant lowering of plasma TG by 11.45 mg/dl, total CHOL by 3.07 mg/dl, LDL-C by 11.05 mg/dl, and systolic blood pressure (SBP) by 6.57 mmHg compared with the controls, but there was no significant difference between groups in HDL-C and diastolic BP. Conclusions: This meta-analysis shows, that RT is contributing to decreasing major risk factors for the metabolic syndrome, such as obesity and insulin resistance and should be recommended in the management of T2DM and metabolic disorders. This study confirms that RT does not increase BP, as it was once thought, and might even have potential benefits on resting systolic BP. Improved glycemic control, decreased fat mass, improved blood lipid profiles and decreased BP are important for reducing microvascular and macrovascular complications of people with IGT or T2DM.

THE BENEFIT OF STRENGTH TRAINING ON ARTERIAL BLOOD PRESSURE IN PATIENTS WITH TYPE 2 DIABETES MELLITUS MEASURED WITH AMBULATORY 24-HOURS BLOOD PRESSURE SYSTEMS
Strasser, B., Haber, P., Cauza, E.
Medical University Vienna, Austria

Background: To give a better representation of blood pressure (BP), while patients are engaging in their usual activities, an ambulatory 24-hour BP monitoring (ABPM) has substantial appeal. ABPM provides automated measurements of brachial-artery pressure over a 24-hour period and provides a highly reproducible circadian profile. The purpose of this investigation was to evaluate the effect of strength training (ST) on BP in patients with type 2 diabetes mellitus (T2D) and to obtain new and important information on BP profiles over 24 hours by using an ABPM. Material and Methods: We recruited ten patients (mean age: 59.7 ± 7.3) from our Diabetes Department who participated in a 4-month systematic ST program on three non-consecutive days of the week. The ST program consisted of exercises for all major muscle groups. The numbers of sets for each muscle group were systematically increased from 3 at the beginning of the program to 4, 5 and finally 6 sets per week at the end of the program. The ABPM equipment (oscillometric Model Mobil-O-Graph® CE 0434) was applied before and after 4 months training period. Routine HbA1c levels were measured using standard techniques. All subjects performed a cycling test to measure maximum oxygen uptake (VO2peak) and maximum workload (Wmax) before and after the training period. Maximal strength was determined by one repetition maximum (1RM) in kg for the bench press, bench pull and leg press exercises, using the Concept 2 Dyno®. Results: Analysis of the pooled day and night time data showed a significant reduction of mean arterial BP (from 93.8±19.2 to 90.6±14.3 mmHg; p<0.01) after 4 months ST (-3.4% mmHg). VO2peak (p<0.05), W max (p<0.05), 1RM for all exercises, using the Concept 2 Dyno®. Results: Analysis of the pooled day and night time data showed a significant reduction of mean arterial BP after 4 months of ST, measured with the ABPM system. In conclusion, these results suggest that ST may not only increase muscle strength, but also decrease BP and perhaps the risk of future CVD development.

ANKLE INSTABILITY AMONG IRANIAN ELITE PROFESSIONAL ATHLETES
Akbari, M., Tadibi, V.
Razi University of Kermanshah, Iran

Objective: Football, basketball, and wrestling are very popular sports in Iran. However, comprehensive information about the prevalence of injuries among professional athletes in these sports is rare. Therefore, the purpose of this study was to examine the prevalence of ankle instability in elite professional Iranian football and basketball players as well as freestyle and Greek-Roman wrestlers.

Methods: 229 male athletes with an average of 23 years old who were invited to the Iranian national training camp (freestyle wrestlers, N=58; Greek-Roman wrestlers, N=68; football players, N=61; basketball players, N=62) during 3 years, participated in this study, voluntarily. Anterior drawer test and tilt test were used to assess ankle instability and mortise view X-ray was performed to confirm clinical diagnosis.

Results: The results showed that the prevalence of the ankle instability was 8.2%, 5.9%, 14%, and 7.3% among free style Wrestlers, Greek-Roman Wrestlers, football players, and basketball players, respectively.

Conclusion and discussion:
The prevalence of ankle instability among Iranian elite professional athletes is relatively high. The prevalence of this chronic injury in football is higher than Basketball and Wrestling, it could be because of higher percentage and intensity of impacts and trauma in football. Strengthening and flexibility exercises; ankle joint protection; and correct diagnosis, treatment and rehabilitation by acute ankle injuries, could prevent this chronic impairment.

PLASMA LIPOPROTEIN AND ADIPONECTIN LEVELS BEFORE AND AFTER DIET/EXERCISE PROGRAM IN OBESE GIRLS

Lac, G., Ben Ounis, O., Elloumi, A., Zbidi, A., Amri, M, Tabka, Z.
BAPS, Univ Clermont, 63177 Aubiere Fr. and Physical Lab, Univ Med Ibn el Jazzar, 4000 Sousse, Tn., France

Introduction.
Several studies indicate that obesity is a major independent risk factor for cardiovascular disease. In this survey, we studied the effects of three interventional programs: diet restriction (D), individualized exercise training (E) and diet plus exercise (D+E) on body weight, metabolic parameters and adiponectin, in obese adolescent girls.

Methods.
The longitudinal intervention study of a 2-month D (500 kcal/day), E (90 min at Lipox max point -intensity of maximal lipoprotein oxidation as determined by indirect calorimetry,- 4 days/week) and D+E (combination of D and E) programs was performed in 18 obese girls (Age 13.2 ±0.3, BMI = 30.4 ± 3.2). Body weight, body mass index (BMI), body fat, waist circumference, homeostasis model assessment (HOMA-IR) index, fasting levels of cholesterol, lipoproteins and circulating adiponectin, were measured in all subjects before and after programs.

Results.
After the program period, in obese subjects of D+E group, body weight (73.1±9.5 vs 78.9±10.8 kg), body fat (27.1±6.6 vs 33.7±4.2 kg), waist circumference (91.1±7.8 vs 96.8±5.4 cm), HOMA-IR index (2.5±3.7 vs 4.5±2.2), total cholesterol (3.82±0.56 vs 4.48±0.49 mmol/l), low-density lipoprotein cholesterol (2.11±0.23 vs 2.79±0.22 mmol/l) and TC/HDL-C ratio (3.21±0.19 vs 4.31±0.42 mmol/l) were significantly lower, and high-density lipoprotein cholesterol (1.19±0.16 vs 1.04±0.09 mmol/l) and adiponectin (3.4±1.6 vs 2.2±1.1 mg/ml) were higher than in either R or E groups. Diet/exercise improved the ability to oxidize lipids at exercise (crossover point: + 18.5 ± 3.4 % Wmax; p<0.01, Lipox max: + 89.7 ± 19.7 mg/min; p<0.01). In D+E group, significant correlations were found between changes in body weight and adiponectin and between changes in TC/HDL-C and Lipox max.

Conclusions.
These findings show that the association of a diet restriction with an individualized exercise training at Lipox max point is necessary to improve simultaneously weight loss and the metabolic parameters. This kind of intervention may be the optimal approach for the prevention and management of childhood and adolescence obesity and the decline of cardiovascular risk factors present in this population.

THE STATE OF MIND DURING PUTTING AND RECOVERY: CAN HEMISPHERIC ASYMMETRIES SHOW DIFFERENCES?

Reinecke, K., Baumeister, J., Weiss, M.
University of Paderborn, Germany

Purpose: There are several investigations about hemispheric asymmetry using the EEG in the preparation period of a motor task to show event-related differences depending on skill level. Less is known in sports sciences about the hemispheric variations of different states such as activation and recovery measured continuously. In order to examine if those variations in central activation patterns can be detected by an asymmetry score a putting-recovery-paradigm with expert and novice golfers was accomplished.

Methods: Nine male expert golfers (25.4±3.9 years; 84.3±8.5 kg; 188.3±3.8 cm) and nine male novice golfers (24.6±3.4 years; 82.6±3.1 kg; 184.3±7.2 cm) volunteered in the study. The experts were characterized with a handicap of 7.2±7.1; 8.0±3.9 years of golf experience in comparison to the experts.

Results: Beside a significant better performance in the expert golfers (p<.001) there were no significant differences in the asymmetry scores depending on skill level. Statistical analysis showed rather a main effect in condition for Theta F3:F4 (p<.05), Alpha 2 C3:C4 (p<.01), Alpha 1 T3:T4 (p<.01) and Beta 1 T5:T6 (p<.05) and an interaction in time x condition for Alpha 1 P3:P4 (p<.03) as well as an interaction in condition x group for Beta 1 P3:P4 (p<.05).

Conclusion: These findings suggest that hemispheric activation during golf putting is not influenced by skill level. In contrast different activation states can be detected by an asymmetry score. Differences in the asymmetry score from performance to recovery are discussed as changes in verbal-analytic and visuo-spatial demands. A decreased ratio from putting to recovery at the temporal electrode positions (T3 T4) in the frequency band Alpha-1 is supported by known decreased visuo-spatial demands in the recovery phase. How ever, using this analyse method it remains unclear how the spectral power at every single electrode position develops from putting to recovery. In summary, the asymmetry score represents a manageable method to give a survey of the state of mind and thereby the way golfers are engaged during putting and recovery.

SAFETY MEASURES IN GOLF - THE ACTUAL SITUATION CONCERNING ACCIDENTS (INJURIES AND DAMAGES) AS REVEALED BY A QUESTIONNAIRE SURVEY OF GOLF COURSES A POSSIBLE MEASURES TO PREVENT THEM

(1)St.Marianna University, (2)Tokyo University, (3)Aichi Mizuho College, (4)Toyama University, (5)Musashino Art University, (6)Ewha Women’s University, (7)Meiji University, (8)Tokai University, Japan

Objective.
We have identified the actual situation concerning accidents and emergency medical services in golf course in the last time through questionnaire survey we sent to more than 2,400 Japanese golf courses during the 21 years. This time, in order to survey the safety situation in Australia district golf courses, we distributed questionnaires to 543 golf courses in "Tokai and Kiriki" district.

Method.
The survey was performed between April 2005 and March 2006. Six questions were as follows: 1) Frequency of ambulances dispatched to the golf courses in a year. Reasons for calling an ambulance 2) Established cooperative arrangement with neighboring hospitals Distances to recommended hospital departments and travel time 3) Emergency medical care available at the golf course and crisis control system. 4) Annual incidence or accidents among golfers.

Results.
(Ambulance calls) Out of 673 golf courses, 102 replied. The response rate was 15%. With respect to the month, there were requests in January (10.7%), April (7.6%), May (15.5%), June (6.9%), June in May (7.6%), June in June (10.7%), in July (16.1%), in August (26.9%), in September (7.6%), in October (8.4%). 14 in November (10.7%), 19 in December (14.6%), respectively. These results indicated that ambulance calls were most frequent in July and June in all regions.

(Emergency medical care system) Concerning emergency medical care procedures at golf courses, 41 golf courses (31.5%) said that "cooperative arrangements with a given medical institution are in place", while 89 courses (68.4%) replied that they had "no fixed cooperative arrangements". About half of the golf courses did not have an established system for cooperating with a given medical institution in case of an emergency. Looking at practical emergency care procedures in the case of an emergency on the golf courses, 62 golf courses (47.6%), the majority had a designated member of staff who would be expected to take charge. 66 courses (50.7%) did not. Seventy-seven 36 courses (27.6%) held training courses for their staff in emergency care, but 81 courses (62.3%), the majority, provided no emergency training.

(Accidents to golfers) Accidents to golfers involving golf balls and clubs had been experienced at 69 golf courses (53%) and had not been experienced at 61 (46.9%). 60 golf courses (46.1%) had experienced accidents due to falls and slips, while 69 (53%) had not. There were 3 accidents resulting in death at 3 golf courses (2.3%) last year. Since the golf courses had been in operation, there had been 36 fatal accidents in total.

Golf is not so physically demanding for middle aged golfers who are receiving sufficient exercise. For this reason they will habitually play additional other sports if they want to improve more score and skill level. This study clarified that middle aged golfers who habitually engage in additional other sports considered golf to be good for their health.

INJURIES ON GYMNASTS: EPIDEMIOLOGICAL STUDY AT PORTUGUESE NATIONAL LEVEL
Reis, M., Rêgo, F., Oliveira, R.
Escola Superior de Saúde de Alcoitão, Portugal

Introduction.
Gymnastics, as a very demanding sport, both physically and psychologically, leads to a bigger injury predisposition for athletes. To determine the annual prevalence of injuries in competitive gymnasts (Trampoline, Acrobatics, Rhythmic and Artistic Gymnastics), at a national level, during the 2005/2006 season; and to characterize its incidence pattern, severity and associated risk factors. This epidemiological knowledge during the practice of gymnastics will allow the development of adequate strategies for injury prevention and the management of risk factors.

Methodology.
A cross-sectional, descriptive and retrospective survey was implemented, through a self-answer questionnaire that was validated and tested. Information was collected in regard to the general athletes' characterization, the practiced sport and the number of sustained injuries. A total of 991 questionnaires were sent to 38 gym clubs throughout the country, with a response rate of 35.2%.

Results.
150 athletes sustained injuries with an annual prevalence of 43.0%, from a sample of 349 gymnasts (21 clubs of national level), with a very young age (average 13.34 yrs). Injuries are more frequent in artistic gymnastics (62.7%), than in Acrobatics (45.6%), and Trampoline or Rhythmic gymnastics (36.2%). The lower limb was the most injured body region (49.6%), in particular the knee, ankle, toe and fingers. Almost four out of ten of the injuries showed recurrence or chronic behaviour. The level of practice with combination of technical elements was the biggest cause for the injury. Gymnasts 15 years and older, with larger amounts of practice time and higher training loads, present a bigger risk for an injury (p<0.05).

Discussion.
The results are comparable with other studies at international level and suggest a high injury risk during the practice of gymnastics. They point towards the need for the continuous intervention of physical therapists. Also, they alert health professionals and coaches to be aware of the risk factors that are associated with the injury incidence. The analysis of associated risk factors is important to promote better prevention strategies.

CHANGES IN SOME ANTHROPOMETRIC, CIRCULATORY AND BLOOD PARAMETERS AS A RESULT OF ANABOLIC-ANDROGENIC STEROID ABUSE IN STRENGTH-TRAINING SPORTSMEN
Boyadjiev, N., Nikolova, J., Muletarov, S.
Medical University of Plovdiv, Bulgaria

Today professional and non-professional athletes abuse anabolic androgenic steroids (AAS) to enhance performance and also to improve physical appearance. Anabolic steroids are wide spread among bodybuilders. AAS are taken orally or injected, typically in cycles of weeks or months. There are many studies on the hazard effects of the AAS abuse (1,2,3).

The aim of this study was to investigate the changes in some anthropometric, circulatory and blood parameters which occur as a result of anabolic-androgenic steroid abuse in elite bodybuilders on national and international level.

One of the best Bulgarian bodybuilding team (n=10) was investigated. The study was performed from October (at the beginning of the preparatory period) to March (at the beginning of the competition period). During this six-month period the following anthropometric, circulatory and biochemical parameters were measured twice: body mass and BMI, 4 skinfolds, the circulatory response during incremental workload (100W/3 min, 150W/3 min, 200W/3 min), blood cholesterol (CHOL), HDL-cholesterol (HDL), triglycerides (TG) and the liver
In the examination of human back pain disorders it can be helpful to use biomechanical devices to find characteristic patterns in bipedal standing.

The videorasterstereographic Formetric®-System is known as gold standard for back shape analysis and reveals parameters that describe posture characteristics like sway back, bent slightly over or normal posture and even posture deviations to the left or right side. On the other hand foot pressure distribution patterns should be associated with characteristics of human standing and can be measured on a pressure platform (Pedoscan®).

A sample of volunteer back pain patients (n=185, 116 females, age 49.6 years (+/-14.3), height 1.68 m (+/-0.07), weight 68.1 kg (+/-12.4); n=185) were examined in normal upright standing by means of back shape analysis (Formetric). The volunteers were examined first in normal upright standing by means of foot pressure distribution (Pedoscan) and immediately after-vards in a positive way: foot pressure analysis serves some extra information in analysis of spine shape and posture by means of videorasterstereography.

We conclude that there is no statistical evidence for any correlation between the posture analysis devices: foot pressure distribution is plane) and R = 0.21 and R square = 4%, SEE = 7.01.

A multiple regression for the pedobarographic parameters shows following coefficients R = 0.24 and R square = 6%, SEE = 4.03 (frontal rotation (forwards-backwards) correlates with trunk inclination: C = 0.19 either (p=.145).

The results are expressed as mean ± SEM (n), of ADULT (AD), OLD (OLD) and OLD-TRAINED (OLD-TR) animals. In summary, these preliminary results indicate that exercise (moderate training) induces a stimulation of the adherence (AD 36.7 ± 8.2 [3]; OLD 45.8 ± 10.1 [6]; OLD-TR 83.3 ± 12.9 [6]; AD vs OLD-TR p<0,05) and chemotaxis (AD 35.3 ± 4.3 [7]; OLD 53.9 ± 13.7 [7]; OLD-TR 129.2 ± 13.1 [7]; AD vs OLD-TR and

**POSTURE ANALYSIS BY MEANS OF PEDOBAROGRAPHY AND VIDEORASTERSTEROGRAPHY: BIVARIATE AND MULTIPLE CORRELATION ANALYSIS**

Schroeder, J., Mattes, K.

University Hamburg, Germany

In the examination of human back pain disorders it can be helpful to use biomechanical devices to find characteristic patterns in bipedal standing.

The videorasterstereographic Formetric®-System is known as gold standard for back shape analysis and reveals parameters that describe posture characteristics like sway back, bent slightly over or normal posture and even posture deviations to the left or right side. On the other hand foot pressure distribution patterns should be associated with characteristics of human standing and can be measured on a pressure platform (Pedoscan®).

A sample of volunteer back pain patients (n=185, 116 females, age 49.6 years (+/-14.3), height 1.68 m (+/-0.07), weight 68.1 kg (+/-12.4)); n=185) were examined in normal upright standing by means of foot pressure distribution (Pedoscan) and immediately after-vards in a positive way: foot pressure analysis serves some extra information in analysis of spine shape and posture by means of videorasterstereography.

The volunteers were examined first in normal upright standing by means of foot pressure distribution (Pedoscan) and immediately after-vards in the same manner by means of back shape analysis (Formetric). The relative foot pressure distributions anterior-posterior resp. mediolateral (%)served as dependent variables for Pedoscan. Pelvis tilt, pelvis rotation, trunk imbalance, trunk inclination and vertebral side-deviation as well as rotation (rms, max right, max left) were taken for back shape analysis (Formetric).

Bivariate (Pearson-correlation, Spearman-correlation and contingency coefficient) and multivariate analysis (multiple linear regression, fixed factors) were calculated to examine correlation and prediction capability.

The mediolateral sway in the foot pressure distribution correlates significantly (p<0.05) with trunk imbalance: r = 0.15 (rs = 0.13). That means an explanation of variance of 2%. The anteroposterior sway in the foot pressure distribution correlates significantly (p<0.05) with trunk inclination: r = -0.15 (rs = -0.12). That means an explanation of variance of either 2%. There are no other statistically significant correlations between foot pressure variables and back shape parameters. Classified results (+/0/-1) lead to an analysis of contingency coefficients. There are no new findings. For the frontal plane the pressure distribution (right-left) correlates with trunk imbalance: C = 0.19 (p= 0.141). For the sagittal plane pressure distribution (forwards-backwards) correlates with trunk inclination: C = 0.19 either (p=0.145).

A multiple regression for the pedobarographic parameters shows following coefficients R = 0.24 and R square = 6%, SEE = 4.03 (frontal plane and R = 0.21 and R square = 4%, SEE = 7.01).

We conclude that there is no statistical evidence for any correlation between the posture analysis devices: foot pressure distribution is independent of posture parameters by means of back shape analysis.

In a positive way: foot pressure analysis serves some extra information in analysis of spine shape and posture by means of videorasterstereography.

**MACROPHAGE FUNCTION IN OLD RATS SUBMITTED TO A MODERATE AEROBIC TRAINING**

Vaisberg, M., Meneguello-Coutinho, M., Costa Rosa, L.

Federal University of São Paulo, Brazil

Disorders of immune function are one of the reasons why elderly people are more prone to infection and cancer, and why these diseases are more difficult to control. An effective method for knowing, preventing or retarding age-related decline in immune function would have impact on clinical and public health. It is well known that moderate physical exercise could have a positive influence in the immune response, so an appropriate regular regimen of moderate exercise might help elderly people to preserve immune function. Macrophages play a crucial role in immune response, as first line defense and act through several mechanisms destroying bacteria, parasites, viruses and tumor cells. Considering the importance of macrophage for the immune response, the possible positive influence of exercise in this cell, we evaluated function of macrophages obtained from elderly rats submitted to a moderate exercise training.

Adult rats (AD), 2 - 4 months, were kept without exercise. The old rats, 15 - 18 months, were divided in two groups, the first one (OLD) without exercise and the second, submitted to aerobic swimming training (OLD-TR) for six weeks. Macrophages were obtained from the intraperitoneal cavity of the rats and we determined macrophage functions by the study of phagocytic, adherence and chemotaxis capacity and hydrogen peroxide and nitric oxide production.

The results are expressed as mean ± SEM (n), of ADULT (AD), OLD (OLD) and OLD-TRAINED (OLD-TR) animals. In summary, these preliminary results indicate that exercise (moderate training) induces a stimulation of the adherence (AD 36.7 ± 8.2 [3]; OLD 45.8 ± 10.1 [6]; OLD-TR 83.3 ± 12.9 [6]; AD vs OLD-TR p<0,05) and chemotaxis (AD 35.3 ± 4.3 [7]; OLD 53.9 ± 13.7 [7]; OLD-TR 129.2 ± 13.1 [7]; AD vs OLD-TR and
OLD vs OLD-TR p<0,05), improving macrophage function in old rats. We also found increased hydrogen peroxide, umol / hour x mg protein-1 (AD 15.9 ± 2.2 (4); OLD 16.9 ± 2.5 [7]; OLD-TR 56.3 ± 7.5 [5]; AD vs OLD-TR and OLD vs OLD-TR p<0.05) and nitric oxide production, uM (AD 43.8 ± 4.3 [6]; OLD 41.6 ± 6.2 [6]; OLD-TR 76.7 ± 12.6 [7]; OLD vs OLD-TR p<0.05) in old trained rats. These changes in macrophage function can help the immune system to cope with bacterial infection and tumor development in elderly subjects, and exercise can be an effective method for preventing or retarding age-related decline in immune function.

MACROPHAGE GLUTAMINE METABOLISM IN OLD RATS SUBMITTED TO A MODERATE AEROBIC TRAINING

Vaisberg, M., Meneguello-Coutinho, M., Costa Rosa, L.
Federal University of São Paulo, Brazil

It is well known that moderate physical exercise have a positive influence in the immune response, so an appropriate regular regimen of moderate aerobic exercise might help to preserve immune function in the elderly. Macrophages play a crucial role in immune response, acting as first line defense and destroying bacteria, parasites, viruses and tumor cells through several mechanisms. Considering the functions of macrophage in immune response and the fact that glutamine metabolism is a very important source for energy and for synthetic activity in immune cells, we evaluated glutamine intermediary metabolism of macrophages obtained from elderly rats submitted to a moderate aerobic exercise training.

Adult rats (AD), 2 - 4 months, were kept without exercise. The old rats, 15 - 18 months, were divided in two groups, the first one (OLD) without exercise and the second, submitted to aerobic swimming training (OLD-TR) for six weeks. Macrophages were obtained from the intraperitoneal cavity of the rats and we determined glutamine metabolism through glutamine consumption, profile of CO2 production by radiolabelled glutamine (Decarboxylation) and Glutaminase maximal activity.

The results are expressed as mean ± SEM (n), of ADULT (AD), OLD (OLD) and OLD-TRAINED (OLD-TR) animals. The results obtained indicate that moderate exercise do not induce alterations in the glutamine consumption (nmol / hour x mg protein-1: AD 1.40 ± 0.35 [7]; OLD 0.97 ± 0.21 [15]; OLD-TR 0.43 ± 0.08 [6]) and glutamine decarboxylation (nmol / hour x mg protein-1: AD 4.28 ± 0.70 [15]; OLD 2.39 ± 0.52 [7]; OLD-TR 1.69 ± 0.17 [6]). The study of Glutaminase maximal activity showed a decrease of the maximal activity in OLD rats and increase in OLD-TR rats (umol / minute / mg protein-1: AD 6.70 ± 2.15 [14]; OLD 3.90 ± 0.74 [7]; OLD-TR 13.98 ± 2.39 [5]; AD vs OLD and OLD vs OLD-TR, p<0.05). The increase in Glutaminase maximal activity could reflect a possible raise in glutamine use, explaining the increase in macrophage and immune functions from animals trained in a schedule of moderate aerobic exercise.

THE PREVALENCE OF MENSTRUAL DISORDERS AMONG ELITE BOSNIAN FEMALE ATHLETES

Medical Faculty University of Banja Luka, Bosnia and Herzegovina

The Female Athlete Triad refers to interrelation among low energy availability, menstrual dysfunctions and bone mineral density. Objectives: To examine the prevalence of menstrual dysfunctions, as a cardinal sign of the Triad, in 84 Bosnian elite athletes and non-athletes control.

Method: Group of athletes was comprised of 34 ball-game players (basketball and handball-National league champions), 27 athletics (17 national team short and long race runners) and 23 dancers, aged between 14 and 25. The control group comprised 31, similarly aged girls, not engaged in any sports activity. We used very detailed questionnaire to determine menstrual profile. Definitions of menstrual disorders (primary amenorrhea, secondary amenorrhea, oligomenorrhea and delayed menarche) were in accordance to ACSM Position Stand. The Female Athlete Triad 2007 [1].

Results: The prevalence of primary amenorrhea was significantly higher in the group of athletes (12/84) than in control group (10/31). The highest prevalence of primary amenorrhea was found in group of athletics girls (8/27). Menstrual irregularities, secondary amenorrhea and oligomenorrhea were reported in 9 of 84 and 11 of 84 athletes, respectively. Five secondary amenorrhoeic and eight oligomenorrhoeic were in athletics (runners) group. No menstrual disorder recorded in control, non-athlete group. The mean age of menarche was substantially delayed (p<0.05) in group of athletes (13.34 ± 1.3) compared to control group (12.73 ± 1.2).

Conclusion: Menstrual irregularities were more frequent in group of Bosnian elite female athletes than in control and the highest prevalence was in runners group.

EFFECTS OF HEAVY RESISTANCE-TRAINING IN WHEELCHAIR ATHLETES

Turbanski, S., Rauwald, I., Schäfer, L., Schmidtbleicher, D.
University of Frankfurt/Main, Germany

Introduction
In several studies with wheelchair athletes endurance training was analyzed, whereas in most experiments forearm ergometer exercise was used. In contrast, little is known about strength training in subjects with spinal cord injury (SCI), especially in high performance athletes. Accordingly, the aim of this study was to evaluate the effects of upper body heavy-resistance-training in wheelchair athletes.

Methods
Sixteen male subjects participated in this study - eight with SCI and eight healthy physical education students conversant with strength training. The subjects participated in an eight-week programme consisting of heavy-resistance exercise performed twice per week. Each training session consisted of 10 to 12 repetitions and 5 sets. All exercise sessions were individually supervised. Subjects’ performances were tested three times: before starting the eight-week program, after finishing the training program and one week afterwards. Movement speed was analysed in a smith machine by measuring maximal velocity and maximal acceleration of the barbell. Maximal strength and rate of force development were assessed by measuring force-time curves in isometric condition. Moreover, we evaluated one repetition maximum (IRM) and Strength endurance (repetitions with a weight representing 60% of the individual IRM). Furthermore, we tested 10m-sprinting performance in wheelchair athletes.

Results
Overall, both groups achieved very similar results. In all parameters we measured an improved performance in post-testing - in wheelchair athletes as well as in physical education students. But the level of significance (<=0.05) was not reached in all pre-post comparisons.

In most strength and power parameters wheelchair athletes show a tendency to a higher profit from the strength training used in this study. But using analyses of group differences only the comparison of effects on rate of force development showed a significant advantage for wheelchair athletes (p=0.01). In 10 m-sprinting performances we found no improvement due to strength training.

**Discussion**

Our data indicate that the effects of heavy resistance-training on strength and power properties in upper extremities are similar in wheelchair athletes and physical education students. In contrast to hitherto assumptions about minor adaptation capacities to training exercises in SCI-patients our study showed clear adaptations to strength training in athletes with SCI. Some wheelchair athletes participating in this study had a spinal cord injury at the level of the cervical vertebrae leading to impairments affecting functional abilities of upper extremities. Nevertheless, they showed strong improvements in nearly all strength and power parameters due to heavy resistance-training.

In conclusion, we suggest that heavy resistance training should be of increasingly importance in wheelchair sports to enhance performance in competition and in daily life activity.

**ANALYSIS OF PSYCHOPHYSIOLOGICAL CONDITIONS OF YOUNG ATHLETES INCLINED TO USING ALCOHOL AND DRUGS**

Petrova, E., Evseev, S., Karotkova, A.

Saint-Petersburg Federal Research Institute of Physical Culture, Russia

**Introduction.** Express-analysis of tendency to using alcohol and drugs for athletes is an important practical and social task. The most common tests are being done using blood analysis, but this approach is quite complicated for everyday sport activity.

**Method of study.** Electro Photon Capturing Analysis (EPC) based on Gas Discharge Visualization (GDV) technique [1] allows measuring the stimulated by electromagnetic field electron and photon emission of human skin. Testing takes 5-7 minutes for a person and can be made in any premises, including training and competition facilities.

**Results.** 120 patients (98 men and 22 women) suffering from chronic alcoholism were studied compared with more than 600 athletes of different levels in sports with high endurance. Averaged age was 24 +/- 6 years. Computer analysis of data using image and artificial intelligence analysis allowed to reveal a set of features of the measured parameters specific for young people inclined to using alcohol and (with high probability) drugs. A set of pathological changes in the psychophysiological condition of athletes using alcohol was found.

The following EPC parameters were correlated with other clinical features:
1. high coefficient of stress in EPC (97 %) was corresponded to high clinical psychology stress (in 98 % of cases);
2. weak pictures with high background; energy deficiency and misbalance of the head zones (96 %) was corresponded to polyneuropathy (75 %);
3. misbalance with energy deficit (90 %) was corresponded to myocarditis anemia (44 %);
4. absence of ECP signal and strong misbalance (84 %) were corresponded to gastritis, enteropathy, hepatitis, cirrhosis (40 %);
5. misbalance. energy deficit with rings on the 4th fingers (64 %) was corresponded to liver increase and dystrophy, pancreatitis (62 %);
6. strong outbursts and many blocks (86 %) were corresponded to myopathy, contraction of musculoskeletal system (70 %).

**Conclusion.** The EPC technique can take a unique position in express-analysis of athletes health and psychological state. This opens broad perspectives for deep scientific research for the developing of new practical technologies.

INHIBITORY RESPONSE ABILITY IN CHILDREN WITH DEVELOPMENTAL COORDINATION DISORDER: A PSYCHOPHYSIOLOGICAL STUDY OF THE POSNER PARADIGM
Tsai, CL, Hsu, YW, Wu, SK, Chiu, HH.
National Cheng Kung University, Taiwan
Purpose: The purpose of this study was to identify and compare attentional, decisional, and motor processing stages of brain activity, as revealed by event-related potentials (ERPs) concerning with deficient inhibitory response ability in children with developmental coordination disorder (DDC) and typically developing children.

Methods: Behavioral performance and ERPs measures were recorded and compared during a variant of the Posner paradigm in 12 typically developing children and 18 DDC children screened with Movement Assessment Battery for Children (Movement ABC). All children reacted to visual targets preceded by a spatial cue.

Results: Children with DCD had significantly longer reaction time than typically developing children whatever the cue-target combination, as well as an elongated interval between the N2 ERPs and the motor response. Children with DCD showed significantly slower N1 latency and smaller P3 amplitude evoked after the target stimuli. Finally, the anticipatory process reflected from the slow negativity (contingent negative variation/readiness potential: CNV/RP) that preceded the target was significantly weak in the DCD children.

Conclusions: These results demonstrated deficits in inhibitory control and abnormalities in brain processes during the performance of a visuospatial attention shifting paradigm in children with DCD.

Key words: developmental coordination disorder, event-related potentials, Posner paradigm

TRAINING TIME AND REST-ACTIVITY ANALYSIS IN NEW YORK CITY MARATHON ATHLETES
Calogiuri, G., Montaruli, A., Roveda, E., La Torre, A., Carandente, F.
University of Milan, Italy
Training can represent an important synchronizing factor that influence the circadian system (1). Exercise can be a strategy to mitigate the problems associated with transmeridian travel. Aim of this study is to verify if the adjustment of circadian rhythm induced by a training program, carried out before a transmeridian flight, can reduce the jet-lag symptoms.

Eighteen volunteers (13 males + 5 females) flew from Milan to New York and back, in occasion of the New York City Marathon, 14 of them participated to the marathon.

Individual training programs were planned for all of the 14 athletes. For a month before the flight, the athletes carried out their training divided. E (Evening), 9 athletes who carried out a training during the evening (19:00-21:00), M (Morning), 5 athletes who carried out a training during the morning (07:00-09:00). Training schedule: at least 3 times a week of 1 hour or more running training sessions (50-60% VO2max). Before the flight, the 2 groups trained for 5 consecutive days with the same intensity, in New York they all carried out the training in the morning. A third group, C (Control), was composed by 4 non-athletes who didn't trained before the flight and didn't participate to the marathon.

Rest-activity monitors were recorded by Actigraph for 3 days before the flight Milan-NewYork (PRE), for 24 hours during the first day in New York (NY1) and during the second day in New York (NY2). The data were analyzed using the actigraph software for the activity and sleep analysis. Activity analysis appraises the activity average score and the cosine peak. The analysis pointed out that activity levels in the M group are higher in New York (NY) than in Milan (PRE), while in the E group are lower. In the C group, activity levels don’t change in NY respect to Milan and are lower than in the M and E group. The before flight cosine peak values are statistically significant different between athletes training in the evening (h 16.19) and in the morning (h 12.07) in PRE data but not in NY1 and NY2. Sleep analysis, carried out to appraise Movement and Fragmentation Index (MFI), demonstrated statistically significant differences between groups M, E and C. In each group, the after flight MFI values were calculated as a percentage of the before flight MFI. In the C and M groups the MFI increases after the flight, while in the evening group the MFI decreases.

In E group the evidence of decreased activity in New York, compared to PRE data, can be explained by the fact that the evening trained subjects had a better sleep quality respect to the morning trained athletes who showed an increased activity levels in NY. Further confirmation of this findings is done by MFI index: it confirms an objective better rest after a EW flight for the subjects that trained in the evening before the travel.

Key words: developmental coordination disorder, event-related potentials, Posner paradigm

GENDER DIFFERENCE IN IRONMAN TRIATHLON PERFORMANCES
Lepers, R.
University of Burgundy DIJON, France
Introduction: The gender difference in endurance performance has received considerably attention in recent decades but most of studies have focused on running (e.g. 1, 2). Physiological and morphological gender differences such as percentage body fat, oxygen carrying capacity and running economy may be responsible for gender difference in running performance. Less information is available on gender differences in swimming (3) and cycling on level terrain (4) when the body does not act against gravity. The gender difference in triathlon however, has received little attention and is poorly understood. Triathlon represents an interesting model because gender differences can be analysed for three endurance disciplines separately and also collectively. The aim of the present study is to examine the gender difference in swimming (3.8 km), cycling (180 km), running (42.2 km) and overall performances at the Hawaii Ironman Triathlon of elite males and females.

Methods: Average swimming, cycling, running and overall time performances of the top 10 males and females at the Hawaii Ironman Triathlon were analyzed from 1981 to 2007.
Results. Hawaii Ironman Triathlon overall performance time of both males and females decreased rapidly from 1981 and then plateaued to present day. The average gender difference in total time for the Hawaii Ironman Triathlon was 12.8 +/- 1.4 %. Average gender difference in time for swimming (10.5 +/- 3.1 %) was significantly lower compared with differences for cycling (P<0.05, 12.8 +/- 2.1 %) and running (P<0.01, 13.4 +/- 3.0 %).

Discussion. Since the appearance of the Hawaii Ironman Triathlon in 1981, elite male and female triathletes improved their performances in the three disciplines. However from late 1980’s, swimming, cycling, running and overall performances plateaued in both males and females despite improvements in training, equipment, and nutrition strategies. Gender difference in time performances in the three disciplines remained relatively constant during the last 25 years. The reduced gender difference in time for swimming compared with cycling and running may be explained by morphological (body fatness) gender differences. In addition, greater leg muscle mass and aerobic capacity in males compared to females may represent an advantage during cycling and running. Gender differences in the Hawaii Ironman Triathlon total performance, is unlikely to change in the future due to the biological gender difference.

ACUTE AND CHRONIC EFFECTS OF CIGARETTE SMOKING ON OXIDATIVE STRESS IN TAEKWONDO ATHLETES
Lu, HK, Lee, HC.
Sport Science Research Center, Taiwan
The purpose of this study was to examine the oxidative stress of smoking on Taekwondo athletes. Sixteen volunteers Taekwondo athletes were recruited from 2003 Taiwan National College Games were divided into non-smoking group (n=8) and smoking group (n=8). The subjects of smoking group must be a habitual of smoker for over one year. Subjects of smoking group were asked to smoke a cigarette immediately after competition. Blood sample were obtained before and after competition. The results showed that malondialdehyde (MDA), superoxide dismutase (SOD), glutathione peroxides (GPx), creatine kinase (CK), and the lactate dehydrogenase (LDH) concentrations were no significant differences between groups before and after competition. It was found that all of these values were out of the normal range compared to normal population. It is concluded that there were no acute and chronic effects of smoking on oxidative stress in Taekwondo athletes. This might be a high oxidative stress background before competition.

EFFECTS OF 12 WEEKS BADMINTON TRAINING ON HEMATOLOGICAL INDICATORS, MORPHOLOGICAL CHANGE OF ERYTHROCYTES, AND MUSCLE DAMAGES
Song, W., Park, KS., Jun, TW., Chang, H.,, Seo, DI., Park, JY., So, WY.
Seoul National University, Korea, South
The purpose of this study was to investigate the effects of 12-weeks badminton training on hematological indicators, morphological changes of erythrocytes, and muscle damages. Thirty-five healthy middle-aged women volunteered for this study and participated in the badminton exercise for 1hr a day at 60~70% intensity of HRH(Heart Rate Reserve) 4 times per week. Blood samples were collected pre-exercise, immediately post-exercise and recovery 1hr in antecubital vein before and after training. RBC (Red Blood Cell), WBC (White Blood Cell), CPK(Creatine Phosphokinase) and LDH(Lactate Dehydrogenase) levels were increased significantly and these changes were continued after 12-weeks training. Hb (Hemoglobin) and Hct(Hematocrit) levels were not changed by a bout of exercise and 12-weeks training. ESR (Erythrocyte Sedimentation Rate), PBS (Peripheral Blood Smear) morphology and ammonia levels were increased significantly by single bout of exercise. However, these changes were not detected after 12-weeks training. Briefly, although the reduction of CPK, LDH levels were not found, reduction of PBS morphology, ESR and reduced amount of ammonia levels were detected, which are considered direct indicators as hemolysis. These results demonstrate that the magnitude of hemolysis were reduced by 12-weeks exercise training.

THE INFLUENCE OF INGESTION GLUCOSE BEFORE GRADED EXERCISE TO EXHAUSTION ON SALIVA IGA CONCENTRATION IN HYPOXIA AND NORMOXIA ENVIRONMENT
Lin, HS., Chang, CK., Fang, SH., Wu, CL.
Taiwan Sport University, Taiwan
Purpose. Exercise and environment stress might induce immune system responses. The study was to examine the effect of glucose drink before exercise in hypoxia and normoxia environment on saliva Iga concentration. Methods: Four male college students completed 4 experimental trials. Subjects were asked to ingest either glucose drink (75g/250ml) or placebo drink 30min before exercise on a cycle ergometer either in the hypoxia or normoxia environment. The exercise intensity initiated from 75W and increased 25W every 3 min until volitional fatigue. The hypoxia environment was set at 15%O2 in a normal baric hypoxia chamber. Saliva samples were collected for 2 min at fasting, before exercise, post exercise and 1 hour post exercise. Results: There were no significant differences in saliva Iga concentrations and saliva flow rate between trials. Conclusions. The current data suggested that saliva Iga concentrations did not affect either ingesting carbohydrate or graded exercise to exhaustion in hypoxia environment.

MAGNETIZATION TRANSFER CONTRAST MR IMAGING OF PATELLAR CARTILAGE UNDER SIMULATED WEIGHT BEARING
Kudo, H., Yamaguchi, T., Mukai, N., Miyanaga, Y., Kuno, S., Miyakawa, S.
Oyama Sports Medicine Clinic, Japan
Introduction
Magnetization transfer contrast (MTC) is an imaging method which creates issue contrast in a different manner as T1 and T2 relaxation time by the exchange of magnetization between macromolecular protons and bulk water, via cross relaxation or chemical exchange. Therefore, it may be beneficial to evaluate articular cartilage using MTC because it has abundant macromolecules, and its function should be specified by macromolecular protons. The purpose of this study was to evaluate the quantitative effects of MTC under weight bearing within the patellar cartilage.

Methods
This study comprised five healthy volunteers and 10 knees. MR imaging was performed with a 0.2T MR imaging system with a knee coil. Gradient recalled echo (GRE) and GRE-MTC sequences to obtain transverse axial images of patellar cartilage were performed to all subjects for 90sec. GRE sequence was TR=500msec, TE=14msec, FA=30deg. The off-resonance sinc pulse was set at a frequency offset of 1.2KHz from the free proton resonance with a duration of 10msec and an amplitude of 12.7x10-6T as preparation for MTC images. GRE and GRE-MTC images were obtained with and without weight bearing. The volunteers performed 15kg simulated weight bearing using special device in the MR machine. The quantitative analysis of patellar cartilage was performed with Ms/Mo between with and without weight bearing. Ms/Mo was calculated as follows: Ms/Mo = SNR with MTC / SNR without MTC, where SNR is signal-to-noise ratio.

Results
Medial and lateral facet of patella cartilage had mean Ms/Mo of 0.90±/-0.03 and 0.89±/-0.05, respectively, before weight bearing. The Ms/Mo of lateral facet with simulated weight bearing decreased by 0.83±/-0.05 and recover by 0.89±/-0.05 and 0.9±/-0.06 at rest after weight bearing (0&8min). On medial facet, Ms/Mo also changed by 0.87±/-0.05, 0.88±/-0.05 and 0.88±/-0.04. However, these changes were not significant (p>0.05).

Discussion/Conclusion
We investigated the quantitative effect of MTC in patellar cartilage to evaluate the influence of weight bearing. The Ms/Mo in patellar cartilage slightly changed between with and without weight bearing in healthy subjects. This result suggests that water content or hydrate states within patellar cartilage changed by weight bearing. The MTC technique would be a promising method to elucidate the effect of weight bearing on articular cartilage.

MOUNTAINBIKE INJURIES IN WORLD-CUP AND RECREATIONAL ATHLETES
Vogt, L., Thiel, C., Himmelreich, H., Pralle, H., Banzer, W.
J.W. Goethe-University Frankfurt/Main, Germany

Introduction
Within the disciplines of bicycling, the popularity of mountain-biking has increased the most. Despite the rising sales and growing numbers of participants, little is known about the discrepancy between typical injuries associated with this sport in world-class and recreational athletes. Therefore the present study investigated the incidence and frequency of injuries in moutainbike sports among competitive and recreational athletes.

Methods
In a retrospective study mountain-bike athletes were interviewed by means of a standardized questionnaire with regard to sports injuries and damages within the previous two years. The study was carried out in the context of world cup racings (Austria, Spain, Switzerland) and public sporting events (Germany). An injury was defined as one preventing the athlete from at least 1 day of mountain biking. In addition subjects were requested to describe the situation that led to the accidents and the protective equipment regularly used. The evaluation of time relative injury-rate was carried out under consideration of class and competition discipline.

Results
Overall 75% of the distributed questionnaires returned completed by 107 World-Cup (39 female, 67 male, 23.1y) and 134 recreational athletes (17 female, 117 male, 27.4y). Approximately 80% of the World-Cup and about 50% of the recreational athletes reported at least one severe injury. World-Cup downhill athletes (1.08 injuries/1000 h) show a more than doubled time-related injury-rate in comparison with Cross-Country athletes (0.39 injuries/1000h). Injuries of the lower (47% vs. 35%) and upper extremity (40% vs. 41%) show comparable prevalence for competitive and recreational cyclists. In the group of recreational athletes open wounds dominate, competitive athletes demonstrate a significant higher fracture-rate (p<0.01). Within the World-Cup athletes head injuries stand out (n=40).

Conclusion
Although World-Cup participation does not result in essential injury-increase, the downhill discipline is characterized by a higher injury risk. Presumably in view of the performance orientation, there is a higher degree of risk readiness. Despite the riding performance and the obligatory safety equipment a remarkable number of bone and head injuries results. In recreational athletes injury preventive measures should address personal factors like risk readiness and anticipation of certain risk situations, and improve the acceptance of protective wear.

A PROPOSAL TO IMPROVE THE MEASUREMENT OF RELATIVE AGE EFFECT IN SPORT
Delorme, N., Raspaud, M.
Université J. Fourier - Grenoble 1, France

Recently, a growing body of research has considered the relationship between athletes’ month of birth and their achievement at the highest level of practice. These studies are based on the concept of ‘relative age effect’ (RAE). This term refers to the difference in age between children in the same age group. Thus, although a child born in January is 11 months older than a child born in December of the same year, both children are grouped in the same age category in an age-based system with January 1st as cut-off date. The RAE has been viewed as discriminating against players born late in the competition year. Basically, differences between children who belong to the same age category but who differ in age up to almost one year could result either in a volunteer dropout of the youngest players, or in an official selection of the oldest players to participate to high level training. Those two phenomena are likely to facilitate an elite career for older players. Among elite adults, this process is reflected by a similar
imbalance in players’ birthdates distribution, with an over-representation of players born during the months following the cut-off date, and an under-representation of players born during the months preceding it. In the literature, the presence of the RAE is determined by testing whether there is a difference between the expected theoretical number of players and the observed number. The theoretical number being calculated from the national population from which the sample of players is taken. This implies therefore that, a priori, we postulate that the distribution of licensed of a particular sport’s dates of birth is the same as the one of the national population. Indeed, apart from some very rare exceptions, the future elite players come from the population of licensed. In order to have a true discrimination, the distribution of the licensed player’s population must be identical with the distribution of birth among the global population of the country. Nevertheless, this assumption has never been verified yet. Using data from the whole French basketball licensed players (n = 443,711), we found a statistically significant RAE.

Those results indicate that the traditional method to evaluate and interpret the RAE cannot always be effective and introduces bias in the conclusions on the phenomenon. Indeed, in the case of French basketball, an unequal distribution already exists among the whole of licensed. In order not to introduce bias into the analysis of the RAE, it is proper to take as the expected theoretical distribution, all licensed rather than the global population of the country studied.

If an unequal distribution already exists among the whole population of players, it is normal by mimicry that one finds it again among elite players. Taking into account the global population of the country, one could be led to hastily conclude that there was discrimination due to the system of recruiting to professional pathways.

ALCOHOL USE, ALCOHOL-RELATED PROBLEMS, PSYCHOLOGICAL HEALTH, AND SPORT PARTICIPATION IN HONG KONG CHinese ADOLESCENTS

Maxwell, J.
University of Hong Kong, Hong Kong

Recently, there has been growing concern about the alcohol drinking habits of adolescents involved in sport, relative to their non-sporting peers. Lorente, et al. (2004) for example, demonstrated that participation in sports (particularly team sports) was associated with increased alcohol consumption in a sample of French teenagers. Similar results have been reported in other Western populations (e.g., Peretti-Watel, Beck, & Legleye, 2002), but none have focused on Eastern populations in which attitudes to alcohol use and sport participation may be very different. Thus, one of this study’s primary aims was to examine the relationship between sport participation and alcohol use in a sample of Chinese adolescents.

Adolescents (N = 1081), from nine secondary schools in Hong Kong, completed a battery of questionnaires examining behavior, health, and beliefs, in classroom settings. The sample was cross-sectional and represented a wide social range. The data were collected as part of a larger study investigating the social behaviors and psychological health of Chinese adolescents. All participants completed a Chinese language version of the Social and Health Assessment (Weissberg, et al., 1991) in normal (quiet) classroom settings and gave informed consent prior to completing the questionnaire pack. A trained research assistant clarified the meaning of questions when necessary.

Contrary to previous research in Western populations, no difference was found between high and low sport participation for alcohol use. Both groups demonstrated equally low alcohol index scores that suggested relatively low levels of alcohol consumption (i.e. no more than one or two drinks in the past thirty days). Despite the low levels of alcohol use, sport participation was associated with binge drinking and alcohol-related problems were more frequent in the high sport participation group, and high alcohol intake was associated with increased probability of alcohol-related problems. Adolescents were more likely to be drunk, get involved in fights, and be arrested if they frequently participated in sport. This finding is novel and suggests that negative reactions to alcohol use may vary with frequency of sport participation. Greater frequency of alcohol use was correlated with pro-aggressive beliefs and poorer psychological health. Girls tended to report poorer psychological health than boys. Boys believed that aggression was more acceptable than did girls.

A SURVEY ON BREACHES OF MANNERS AMONG JAPANESE GOLFERS -COMMENTS OF GOLF COURSE MANAGERS

Kita, T., Horie, S., Yoshihara, S., Ymamoto, T.
(1)Tokai University, (2)St.Marianna University, (3)Musashino Art University, Japan

[Introduction]
The R&A Golf Rules declare the importance of etiquette and manners as the “spirit of golf” at the beginning of Chapter 1. The rules also state that those who have acted in a way considered as a serious violation of etiquette should be expelled from the game as a penalty according to Article 33-7. In light of these facts, this study was conducted to clarify the current status of golfers’ observance of etiquette and manners, which should indicate their essential quality. More specifically, a questionnaire survey was conducted among golf course managers across the country to have them answer two questions: “Does a breach of manners often occur these days?”, and “If so, what does such a breach involve?”

[Methods]
A questionnaire was mailed to 1,893 golf courses in Japan. Responses were collected from 902 courses (response rate: 47.6%).

[Results]
The answer “A breach of manners often occurs these days” accounted for 80.8%, and the total number (M.A.) of breach cases was 1,236 (cumulative). The collected responses were all categorized and summarized. The most common behavior mentioned as a breach included “slow play” (25.0%), “violation of the dress code” (21.0%), followed by “not repairing divots and ball marks” (10.8%), “filtering of cigarette butts and waste” (9.9%), “not repairing the bunker” (5.3%), “smoking during the game or in a non-smoking area” (4.9%), “driving the golf cart onto the fairway or in a reckless manner, breaking or overloading the cart” (2.8%), “cancelling at the last minute or without notice in the case of rain” (2.4%), “being late for the start time” (2.3%), “shooting into the preceding group” (2.3%), “golf manners in general” (1.8%), “using cell-phones during the game or in a prohibited area” (1.5%), “not repairing the turf” (1.1%), “individual practice on the
A total of 193 people responded to the questionnaire (14.5% response rate).

It was found that 72.5% of the commercial sports leaders had some qualifications. “Fitness Leader” of the Japan Health Promotion & Fitness Foundation was the most common qualification, followed by “Fitness Practice Leader” of this foundation, “C-class Instructor” and “CPR” of the Japan Red Cross Society, “Swimming Teacher” of the Japan Sports Association, “NSCA-CPT” of NSCA Japan, “Teacher’s Licenses of Health and Physical Education of Secondary Schools” of the Ministry of Education, Culture, Sports, Science and Technology, “ADI” (Aerobic Dance Instructor) of the Japan Aerobic Fitness Association, “Sports Programmer” of the Japan Sports Association etc. In addition, more than half of them (53.9%) answered that they were going to obtain some qualification in the future.

MARKETING AT SPORTING GOODS SHOPS IN JAPAN -RELATIONS WITH AGE OF OWNERS AND NUMBER OF EMPLOYEES-

Horie, S., Kita, T.
Tokai University, Japan

Introduction

In recent years, the Japanese sporting goods retailing industry has been suffering economic slowdown (Matsushita,1998). We previously presented the current status of sporting goods shop management in Japan and its challenges (Horie,et al.,2006)(Kita,et al.,2006). This study was intended to characterize the marketing strategies of sporting-goods stores in Japan based on the age of owners and number of employees.

Methods

From the 17,949 retail sporting goods shops listed in Japan, 880 shops were selected at random for this survey. Survey period was June 1 through August 31,2005. The questionnaire was delivered by mail and responses were collected by mail. Responses were collected from 180 sporting goods shops (percentage of respondents: 20.5%). All data were analyzed using unpaired t-tests. All in cases p<0.05 was considered statistically significant.

Results

The major findings are shown below:

Owners aged 49 or younger revealed a significantly higher rate of using "posters" as a means of advertisement than those aged 50 or older. (p<0.05) Owners aged 49 or younger showed a significantly higher rate of using the "Internet" as a means for market research than those aged 50 or older. (p<0.05) Owners aged 50 or older demonstrated a significantly higher rate of not conducting market research than those aged 49 or younger. (p<0.01) Owners aged 49 or younger revealed a significantly higher rate of using "others" as a means for market research than those aged 50 or older. (p<0.01) Owners aged 50 or older showed a significantly higher rate of emphasizing the "trend of leisure" as a standard for stock composition than those aged 49 or younger. (p<0.01) Owners aged 49 or younger...
demonstrated a significantly higher rate of answering that they would “increase the volume of stock procurement” as a measure for profit increase than those aged 50 or older. (p<0.01) Shops with 30 or more employees were noted to show a significantly higher rate of using “newspapers” for market research. (p<0.01) A comparison of shops per number of employees identified significant differences in the rates of using “newspaper leaflets” (p<0.01) and “direct e-mails” (p<0.05) as a means of advertisement. It is our future task to conduct more focused, in-depth research based on these results.

THE ROLE OF THE SPORT AND PHYSICAL EDUCATION IN THE CONTEMPORARY SOCIETY FROM THE GLOBALIZATION PHENOMENON VIEW POINT

Mihailescu, L., Mihailescu, N., Macri, A., Butnariu, M., Mihai, I., Cajanu, F., Valcu, B.
University of Ploesti, Romania

Introduction
From the overall view point, in the 58/5/2003 Resolution of the U.N.O. it is said that: sportive activities represent an ideal field to promote and develop the motivation and self exceed of the individual; sport represents an opportunity of each individual to evaluate himself, sport facilitates each person to become the only responsible for his own future, and give it a mean; sport will be the mirror of life, with the perspective of the human continuity, the tolerance and understanding for a world with universal values of peace, friendship and collaboration.

Content, methodology
All the activities proceed all over the world in 2005 on the occasion of The International Year of Physical Education and Sport Concept promotion, and after, emphasized the contribution of the two activities in order to achieve the U.N.O. objectives for development. The decree of the international year created the unique opportunity to convince the political and social area the power / role of the sport to capture the attention and to rally the individuals, organizations, communities and common public to accomplish objectives.

We conceived our approach as an applicative and sociological research, materialized in answers to the following questions:
- who has the responsibility to promote the Physical Education and Sport valences?
- which are the objectives concerning the professional training of the domain specialists in order to comprise the benefits of the Physical Education and Sport in social life?
- what is the trend of the domain in the globalization politics?

Conclusions
- promotion responsibility belongs to the domain specialists, all the specialists from other domains that serve physical education and sport domain: teachers doctors, psychologists, sociologists, nongovernmental and governmental institutions for sport and those with competence in physical education and sport area;
- the objectives of the professional training are reflected in the globalization concept, where all the social life domains will be approached from their universality perspectives;
- the reflection in social plan is materialized in the strategy of changing the battle field to the ground field.

FAIR PLAY AND GLOBALIZATION IN SPORTS

Atalay, A.
Marmara University, Turkey

In our age, what are understood from globalization are reduced functions of national governments, disappearance of the borders and most importantly free circulation of the capital in the international arena without encountering any obstacles. As a result of these, the materialist world-view displaces all manners of humane constituents in the whole world and in all areas of the culture. Besides, considering the identity issue and the loneliness of human beings of our age, sports is not an apparent reality, instead it can be called “image producing”. These socio-cultural changes have removed the contents of Fair Play concept which is an Olympic ideal. Concepts like peace, brotherhood/sisterhood, sportsmanship, friendship, compliance with the rules, not taking advantage of the opponent’s disadvantage, joy of playing with the opponent instead of defeating replaced the greed of money and profit, professionalism, doping, trade, politics, total circulation and rating concerns and trade marking. Also as a result of multi-national companies’ interference in the sports arena, winning at the cost of whatsoever, getting more profit, competing against others instead of themselves, being superior, etc. has replaced the fair play manner radically. Ideology of globalization in the direction of sport has lost it’s characteristics of being a demonstration of peace, brotherhood/sisterhood, and friendship. China being the host of 2008 Olympics where huge violations of human rights are seen, displays how globalization negatively affected the Olympic soul. Because, China with a population of 1 billion 250 thousand, whets the sports industry’s appetite. Globalization is not only causing the fair play manner to be sacrificed for economic profits sake, but also as signs the nationalism to the use of market economy. Globalization endangers the “start equity” in sports at the beginning. In this context, fair play concept should be considered in a macro level, instead micro. Considering fair play in a micro level means to abstract the sports from its economic dimension. In this perspective, fair play concept should be considered as pluralistic, instead of particularistic. Considering fair play in a pluralistic manner will play a significant role in removing inhuman exploitation in sports industry. To permit sports indus-
try workers to organize themselves into a labor union, not to keep workers salary low, to comply with daily working hours are important provisions for the operator of sports industry. The consumers of the sports industry also have important responsibilities. Sports consumers should make sure that products or services that they get are produced under social conditions.

**EDUCATION AND WELFARE PROVISION IN PROFESSIONAL FOOTBALL ACADEMIES IN EUROPE: SOME SOCIOLOGICAL COMMENTS**

Platts, C., Smith, A.  
*University of Chester, United Kingdom*

In the wake of England’s failure to qualify for the 2008 European Championships in Switzerland and Austria, an abundance of ex-players, managers, ex-managers and journalists have clamoured to offer their thoughts and ideas on the reasons behind the seemingly poor qualifying campaign. In this regard, some critics have pointed towards the shortcomings of the professional football academy system in England at producing the necessary talent, suggesting that the English academy system should take on the form of the academy systems around the world, particularly those in Europe. This paper, therefore, seeks to examine how these wider European developments are impacting upon the day-to-day operations of professional football academies in England, and especially the educational and welfare provisions young players receive therein. In doing so, the paper provides a comparative analysis of English and other European professional football academy systems.

**“PROMOTING GIRLS’ SPORTS PARTICIPATION” - A QUESTION OF POWER AND NORMALISATION**

Svender, J.  
*The Swedish School of Sport and Health Sciences, Sweden*

Sport is an essential identity-producing arena and gender is a crucial part of the identities shaped and formed there. Previous research claims that the relationship between women and sport appears to be more problematic than that between men and sport, since sport is still discursively positioned as a masculine practice. In Sweden, being a member of the sports movement is almost as common for girls as for boys. More than two out of every three boys and every other girl between the ages of 7 and 15 is a member of a sport club. The sports movement is considered to be a significant institution for socialisation - not the least gender construction.

Regarding gender as something that is produced and enacted through discourses, prompts an investigation into the discourses that form, and are formed by, the practice of sport. Inspired by feminist Foucauldian theory, the aim of the research is to analyse the discursive construction of “girls” in a large-scale government initiated sports project. Local sport clubs were in this context encouraged to work with projects that “promoted girls’ sports participation”, for which they could apply money. Project applications written by sport clubs in three traditional male-dominated sports constitute the empirical material of the study. The study’s central questions, as well as the analytical ones, are: what does “promoting girls’ sports participation” mean; what is to be done and why? How are girls portrayed and what kinds of girls are targeted in the projects?

The analysis shows that girls and their participation in sport are portrayed in a rather homogenous way: girls are something “special”, and that so far their participation in these male dominated sports has been limited. This seems to motivate a separation of girls and their sports from “ordinary” activities, which implicitly means activities for boys.

Using Foucault’s concept of normalisation, distinguishing girls by accentuating their specialty make sense. Forming categories and ascribing them certain characters, interests and competences, in the way it is done in sports projects, makes these projects - and the sport itself - possible and meaningful. But in practice, this normalisation could be a way of governing and disciplining individuals in certain directions, i.e. a form of modern power, in Foucault’s words. One consequence of normalisation is that projects aiming at “promoting girls’ sports participation” target certain girls and the resulting category of girls is attributed certain features. The group of girls is thus stereotyped and homogenised; something that limits the possibility of alternative and flexible identities and makes other types of girls invisible. From a feminist point of view, these are crucial issues.

**THE ASSESSMENTS OF SPORT MANAGEMENT STUDENTS’ VIEW TOWARDS THE RELATIONSHIP BETWEEN SEX ROLE STEREOTYPES AND REQUISITE MANAGEMENT CHARACTERISTICS**

Alay, S., Kocak, S., Karakılıç, M.  
*Gazi University, Turkey*

The purpose of this study was to explore undergraduate female students’ assessments towards relationship between sex role stereotypes and requisite managerial characteristics. 194 undergraduate female sport management students were participated in this study.

Turkish version of Schein Descriptive Index (Schein, 1973) was used to evaluate undergraduate female sport management students’ view about sex role stereotypes and requisite managerial characteristics. The instrument has three forms containing the same descriptive terms and instructions, except that one form asked for a description of women in general (Women), one for a description of men in general (Men), and one for a description of successful middle managers (for this study, this form asked for a description of successful middle sport managers). The ratings of the descriptive terms were made on a 5-point scale, ranging from 1 (not characteristic) to 5 (characteristic) with a neutral rating of 3 (neither characteristic nor uncharacteristic).

Participants filled out only one form of the index. The index was given to 194 female sport management students at their regular class hours. Completed questionnaires were included in the study.

Intraclass correlation coefficients from two randomized-groups analysis of variance technique was used to determine the degree of similarity between Men and Mid-level Sport Managers, and between Women and Mid-level Sport Managers. The classes (groups) were the 92 descriptive items. The same procedure was applied for each of the four grade levels to learn if grade levels moderate these relationships. Pearson Product correlations were computed to determine the linear relationship between the mean ratings among four grade levels.

The results of ANOVA and the intraclass correlation coefficients indicated that there was a significant resemblance between the ratings of Men and Mid-level Sport Managers ($\rho = .82$, $p < .01$) and Women and Mid-level Sport Managers ($\rho = .84$, $p < .01$).

Also, there was a significant resemblance between the mean ratings of Men and Managers ($r’$grade1= .80, $r’$grade2= .83, $r’$grade3= .79, and $r’$grade4= .83, $p < .01$), and Women and Managers ($r’$grade1= .82, $r’$grade2= .85, $r’$grade3= .86, and $r’$grade4= .80, $p < .01$) in terms of
grade levels. Pearson Product correlations were computed to determine the linear relationship between the mean ratings among the four grade levels. 

The results revealed that successful middle sport managers are perceived to possess characteristics, attitudes, and temperaments more commonly ascribed to women in general than to men in general by the subjects. There are resemblances between the ratings of Men and Mid-level Sport Managers and between the ratings of Women and Mid-level Sport Managers among female sport management students, and also among grade levels. It might be concluded that sport management female students do not view any gender differences regard to requisite managerial characteristics in terms of sex role stereotypes. As a conclusion, female sport management students perceive management as a unisex profession.

DESIGN OF A SOCIO-EMOTIONAL QUESTIONNAIRE FOR YOUNG SOCCER PLAYER

Gómez, P., Benito, P., Duran, J., Noya, J.
Technical University of Madrid (UPM), Spain

To carry out the first step of any research, which is no other than the approach to the question or the identification of a need, we have taken into account the illusion which day by day can be seen on a football ground. The need is no other than improve the approach of plans to help young footballers from big team’s football base.

Sometimes sport success or failure, due to certain abilities, is based on particular factors related, to begin with, the personal and familiar surroundings, and secondly, the condition in which he develops his preparation. This factors can have a huge influence on the sports performance and development, and also on the future elite sportsman evolution (Donohue, Miller, Crammer, & Cross, 2007; Holt & Tom, 2006; VanYperen, 1995). Garcia and collaborators go a step further, pointing that the surrounding conditions are as crucial as the genetic factors (Garcia, Campos, Lizaur & Bablo, 2003).

Among all the requisites which determine that a young sportsman plays on the main division, only and not always aspects as technical-tactical, physical and psychological could be controlled. On the other hand the socio-emotional aspects which we believe are as important as the above named are ignored. Consequently, the purpose of this work is to design a tool that detects and controls the socio-emotional factors that could influence the young footballer’s progression on sports.

Following the identification of the need, the current project tries to cover it specifying and controlling these parameters traditionally forgotten. Therefore, we have prepared a socio-emotional questionnaire of 42 items which inform us of the player’s social environment and his ability to handle the problems on such an environment. The questionnaire is comprised by the following dimensions:

1. Social class.
2. Family Relationship.
3. Relationship with the coaching staff.
4. Relationship with teammates.
5. Relationships with friends or peers.
6. Relationship to the school environment.
7. Partner Relationship.
8. Stress.
10. Emotional Intelligence.
11. Moral development.
12. Type of residence.
13. Public/Spectator

EXPERIENCING OF PAIN AND INJURY AMONGST PORTUGUESE PROFESSIONAL FOOTBALL PLAYERS

Pimenta, N., Pinheiro, C.
Instituto Superior da Maia, Portugal

Modern sport is characterized by a growing competitiveness which according to Waddington and Murphy (1992) is associated with an increasing politicization and commercialization of sport. However this competitiveness has significant health cost for athletes, more precisely in the form of pain and injuries resulting in overuse and recurrent injuries that through time can become permanent. Athletes are enmeshed in large networks of interdependency thus being interdependent with a large number of people (such as coaches, medical staff, supporters, club boards and other players). This will probably compel them to act in ways that “they would not act except under compulsion” (Elias, 1980: 102). Since they are involved in multipolar relationships athletes feel constrained to continue practicing and competing independently of their physical condition. According to Waddington (2006) athletes with time come to accept pain and injuries as something normal and a part of the life of an athlete.

The main goal of this paper is to examine the experiences of pain and injuries of Portuguese football players. It was also our intention to understand why they continue practicing and competing while injured. The data was gathered through semi-structured interviews. Eight Portuguese professional football players were interviewed (three of them played in Liga de Honra and five played in Superliga). The interviews after being transcribed were submitted to content analyses.

All players mentioned that they had, at least once, played while in pain and injured. They mentioned taking pain-killing injections in order to continue playing for the good of the team. Due to their direct or indirectly interaction with other members that belong to the club structure, players refer that those members try to encourage them to play and practice with pain and injuries. In many cases the players are the ones who try to pressure the medical staff and the manager to continue playing in spite of pain and injuries and being physically...
diminished. They feel compelled to play due to the nature of their profession. Amongst the reasons to continue playing while in pain or injured is the fear to lose their place in the team, which may have repercussions upon their contracts. The discourse of our interviews is in accordance with what the literature mentions to be a normal practice at this level of competition. There is a latent ‘culture of risk’ which tends to normalize playing and practicing while in pain or injured, which can have important long term health risks for the athletes.

YOUNG PEOPLE AND FREE TIME: REPRESENTATIONS AND PRACTICES

Pereira, A., Moreira, M.
Polytechnic Institute of Viseu - Higher Education School, University of Trás-os-Montes and Alto Douro, Portugal

Free time constitutes a central issue in the social dynamics sphere which shapes the contemporaneity of young people Larson & Seeperssad, 2003). The attitudes and behaviour shown during this time are determinants in defining their education and development (Marshall et al., 2004; Parr & Lashua, 2004). The purpose of this study was to identify young people’s representations of free time, to study the activities carried out during this time and examine the implications for their education. The study was carried out on 70 young people attending 9th year in state schools in Aveiro and Coimbra using semi-structured interviews. The technique used for data analysis was content analysis. (Strauss & Corbin, 1998). The elaboration of the categories had been defined a priori and a posteriori. (Bardin, 1977). The computer programme of qualitative data analysis QSR NVivo 7 was used in coding the transcripts of the interviews.

Free time is the personal time which is left in the use of the individual. It is the time when the values of the activity are those of the individual and not the ones of the group. (Parr & Lashua, 2004). Free time is defined as a personal pleasure which is not public (Parr & Lashua, 2004). Free time is the time which the individual has when he can do what he wants to do. Free time is a personal task which is not imposed by the group (Parr & Lashua, 2004). The individual can choose what he does in his free time (Parr & Lashua, 2004). Free time is the time when the individual can follow his own desires and not the desires of the group (Parr & Lashua, 2004). Free time is the time when the individual can do what he wants to do (Parr & Lashua, 2004).

Most of these free time activities are unstructured, carried out in the absence of adults, who coordinate and orientate them. The predominant activities are watching TV, computer usage (video games) / Internet, sport, and listening to music. The main reasons for these activities are fun and the development of new skills, which are carried out alone, with friends, with family and in the community. These trends should be considered by families, schools and other responsible institutions in order to adjust their multiple forms of intervention, taking into account young people’s interests, but following formative and educational principles.

ATP AND WTA WORLD RANKINGS: A STUDY OF THE TOP PLAYERS TENNIS LONGEVITY
Teixeira, M., Barros, C.
Universidade de Évora / Instituto Superior de Economia e Gestão, Portugal

This paper analyses the duration of top tennis players’ careers using data from the Association of Tennis Professionals (ATP) on male top players from 1973 to 2007 and from the Women’s Tennis Association (WTA) from 1998 to 2007. To do so, several hazard models are adopted to take into account the recurrences observed when the same player is reclassified top player. The results show that the most important factors are the player’s total career prize-winnings, singles matches won and the individual’s height, in addition to the number of recurrences registered at the top of the rankings. Furthermore, gender plays a role. We also find some evidence that US players have longer careers than European and Australian players. The policy implication is derived.

PHYSICAL EDUCATION AND FOLK DANCES COURSE IN VILLAGE INSTITUTES CURRICULUM IN TURKIYE
Çelik, V., Bayrak, C.
Anadolu University, Turkey

The struggle to solve the problems of the country through educational institutions existed both before and after Republic period. The so-called educationist’s project Village Institutes were founded to substitute for traditional establishments. The principles of new concept of education were different from these of the traditional, which was an extension of the revolution launched by superstructural factors. When the first Turkish Government was founded during The War of Independence (1919-1922), education was one of the primary issues to receive attention. The renovation and modernization of Turkey’s educational system was planned to be carried out by considering our own social and cultural features. The problems about education were not neglected even in most critical periods of the war. After the victory the founders of the new country were naturally able to make more energetic efforts to improve Turkey’s much neglected educational system. One of these enormous effects is exactly the experience of Köy Enstitüleri (The Village Institutes). This project has been reflected the revolutionary character of the Republican Reforms. The teaching philosophy these institutes has been described on the basis of learning by doing.

21 Institutes were founded in different regions in Türkiye for developing rural areas. Village Institution Curriculum was prepared by Türkiye ministry of education in 1943. Courses were configured three main titles in the Village Institution Curriculum. These were Agriculture Courses and Practices, Technical Courses and Practices and General Information Courses. Physical Education and Folk Dances Course was one of the courses in General Information Courses. This course was took placed four years and 184 hours in Village Institution Curriculum.

Village Institutes founded in 1937 was closed down in 1954. 17.341 teachers, 8.675 educators and 1.599 health officers were trained until 1954 when Village Institutions were closed. So many poets, authors, researchers and educators were graduated from these institutions. The Model of Village Institution has been accepted as a great gift not only for this nation but also for the world education. UNESCO has proudly stated that Village Institution is an education system being an example for all the developing countries. In this research as well, the content, objects and applied dimension of Physical Education and Folk Dances Course which is one of the courses in the Village Institution Curriculum and the effects of this course that have on students in that period will be analyzed with the relations done one to one. For this purpose, prepared a interview form and had interviewed Village Institution graduates who have lived in Eskiehir.

ABUSED ATHLETES’ PERCEPTIONS OF THE COACH-ATHLETE RELATIONSHIP
Stirling, A., Kerr, G.
University of Toronto, Canada

The coach-athlete relationship is often one of the most important and influential relationships experienced by a young athlete (Gervis & Dunn, 2004). While coaches may have many positive influences on young athletes, emerging literature also indicates problems of abuse. In fact, recent research indicates that athletes are not immune from experiences of physical, sexual, and emotional abuse (Kirby & Greaves, 1996; Stirling & Kerr, 2007). Furthermore, the power of the coach is thought to be a contributing risk factor in abusive relationships (Bringer, Brackenridge, & Johnston, 2001). The purpose of this study therefore was to investigate abused athletes’ perceptions of the coach-athlete relationship. More specifically, we were interested in abused athletes’ perceptions of the power held by the coach, and the influence of this power on an athlete’s experience of abuse. Semi-structured interviews were conducted with 9 athletes who had experienced at least one form of abuse; 4 retired elite female gymnasts and 5 retired elite female swimmers. Consistent with previous research, the participants reflected upon the significant power held by the coach over the athlete. The findings contributed to existing literature by revealing specific ways in which the coach’s power influenced the athletes’ experiences of abuse and their ability to report incidences of maltreatment. These findings are discussed and recommendations are made for abuse prevention and future research.

COMPARISON OF SCORING IN THE 2004 ATHENS OLYMPIC SINGLE AND DOUBLE TABLE TENNIS

Barmaki, S., Gharakhanlou, R., Khazani, A., Kaseb, F., Ziaee, N.

The aim of the present research was the comparison of scoring by defensive and offensive tactics and techniques, and also studying the importance of defense and the role of service points in world-class table tennis. The collected data for this research is related to 172 table tennis players who participated in the 2004 Olympic Games. This data was collected through information that was given to Iran’s table tennis representatives. Based on this, the points gained using different tactics and techniques by male and female athletes were studied and compared. Results show that 34% of points were gained through offensive techniques and tactics (after 3 shots were played), 33% through defence and counterattacking, 25% through the third shots and serving, 8% through other shots in sing table tennis, so those show that 38% of points were gained through defense and counterattacking, techniques and tactics, 31% through offensive (after 3 shots were played), 24% through the third shots and serving, 7% through other shots in double table tennis. The same results where achieved for the top 4 players. Also there was significantly in defensive tactics in and counterattacking techniques in sing table tennis of top 4 players of men than women (p<0.05). No significant differences were found in other items between women and men groups (p>0.05).

Based on these statistics, coaches and players should strongly consider the defensive tactics and serving techniques along with the effective offensive tactics in order to reach world-class success.

THE SOCIAL ASPECTS OF THE POPULAR RUNNING RACES OF THE CITY OF CURITIBA/BRAZIL

Stanganelli, P., Gonçalves, M.
Curitiba City Hall - SMEL and Catholic University - Brazil, Brazil

Introduction.
Curitiba is a city located in the south of Brazil with 1.800.000 inhabitants. Since the 70s this city has public policies aiming to the improvement of quality of life of its population through special programs which include sports and leisure activities. One of the programs has been the promotion of running races in a regular basis annually for the city athletes and general public as well. The races occur always on Sunday mornings and the course is 10 km long and the participants must be over 16 years old. There are also races with shorter distances for participants aging from 12 to 16 years old. This kind of running races is a democratic way to stimulate participation of the individuals considering they come from different age-groups and technical backgrounds and all of them share the same event held in the streets of Curitiba providing the runners a chance to circulate through many sceneries of the City.

Objectives.
The objective of this study was to know some social aspects related to the participants registered in the races promoted by the Sport and Leisure Department of the city of Curitiba-Brazil.

Methods.
A ten questions questionnaire was applied to the runners. A sample of 200 runners answered voluntarily the instrument in events held in 2006 and in 2007.

Results.
The results showed that 77% and 33% of the runners were male and female, respectively. 49% of them run regularly for less than five years and 31% is involved in this type of activity to maintain their health. 41.5% train regularly in the streets of the city and 26.5% in the streets of Curitiba providing the runners a chance to circulate through many sceneries of the City.

The results showed that 77% and 33% of the runners were male and female, respectively. 49% of them run regularly for less than five years and 31% is involved in this type of activity to maintain their health. 41.5% train regularly in the streets of the city and 26.5% in the streets of Curitiba providing the runners a chance to circulate through many sceneries of the City.

Conclusion.
According to the results it seems that the popular races represent a process of social inclusion since by running regularly they could obtain and keep healthy benefits from this sport as well as they have to keep in mind some sport values such as knowing new people and competing against them in a fair play basis. Through the popular races and based on the concepts involved in this kind of event it is possible to state that this sport could be understood as a manifestation of the popular culture.

PETROPOLIS SPORTS AND LEISURE PUBLIC POLICIES-ANALYSIS OF THEIR IMPACT ON THE FORMATION OF CITIZENSHIP AND THE DEVELOPMENT OF THE POPULATION

Farjalla, R.

The subject of the survey are the public policies carried out by the City of Petrópolis, State of Rio de Janeiro, Brazil, aiming at utilizing sports and leisure as a means to promoting citizenship and population development. With the objective of beginning a process of enhancing access of the less favored to leisure, sports and other activities in schools, several projects were forwarded in that connection. Thus a new era began of expressive modifications of the picture heretofore observed. However, the system was lacking in evaluation methodologies - very much needed in order to provide valuable information as to the efficiency and the effectiveness of said policies.
2) the accuracy of choice in what regards the cultural, social, economic and financial return of the investment made in the field;
3) the equipment and facilities engendered by the new practices;
4) the improvement in the population’s quality of life, especially in what refers to health. The research began in 2005. The qualitative and descriptive methodology used was the application of the classical questionnaire to one hundred children - Tubino (2006). The analysis granted by the gathered information lead us to the perception that the present situation - after the rendering of the new policies, starting in 2001 - was some aspects (qualitatively, for instance) 60% superior to the previous one. The universe covered comprises 60,000 students of 67 municipal schools.

PROMOTION OF TALENTED ATHLETES IN CHINESE COMPETITIVE SPORTS

Miao, J.
Institute of Physical Education, China

Within Chinese competitive sports, the athletes are classified into three different categories: The first class athletes, the second and the third class athletes.

The term First Class Athletes refers to the members of the national team and the big teams of the provinces and towns. Second Class Athletes are they who have had a certain base of training and who are considered to be future top athletes.

Third Class Athletes are gifted, young, developing athletes who exercise in leisure sport clubs.

There are several ways of recruitment and promotion in the Chinese system of competitive sports.

First of all it is practiced at normal schools and universities. Sports is the one of the most important subjects at school, right after foreign languages.

Athletes who are very good at school and who are noticed by the teachers can change school and go to a particular school which promotes athletes.

Very talented athletes go to special sports schools (so-called leisure sport schools or colleges of physical education for youths) or join the province- or national teams.

The aim, which is to be achieved here is to train the young athletes for competitive sports in a different environment from normal schools. In the colleges of physical education the syllabus of the other subjects is not as important as the interests of the competitive sports but a reduced curriculum is certainly provided by the schools.

PP-TT01 Training and Testing 1

ANTHROPOMETRIC AND FUNCTIONAL PROFILE OF YOUTH TALENT VOLLEYBALL PLAYERS

Simões, M., Soares, J.
Instituto Politécnico de Viana do Castelo, Portugal

The central objective of this study was to identify the anthropometric and functional profile of male youth volleyball players. In addition, we intended to find the anthropometric and functional profile of volleyball players depending on the specific position played in the competition.

The sample was composed of 50 athletes, 19 belonging to the Youth National Team and 31 athletes who have not been selected, aged between 15 and 17 years. The study took place on the following factors in performance:

1. Anthropometrics—were made 24 measurements body, including, in addition to height and weight, length, diameter, perimeters and folds of adiposely subcutaneous;
2. Body composition and somatotype;
3. Functional tests were performed to assess the explosive strength of the upper and lower members, the maximum strength of the lower limbs, aerobic endurance, speed and the strength of speed.

The results showed statistically significant differences among the athletes selected and not selected in functional and anthropometric variables. The functional variables, including the reach (of attack and block), the maximum strength of the lower limbs and anaerobic power, showed a greater power of discrimination of the groups regarding the anthropometric variables. The analysis of profiles depending on the specific position showed that the setters and liberos presented profiles similar among themselves but quite distinct from attackers, especially those opposites and central players.

The data suggest the existence of anthropometric and functional distinct profiles in the selected athletes comparatively to the not selected ones and of a differential between the diverse played specific functions in the competition.

CHRONOTROPIC RESPONSE IN EXERCISE-TRAINED ADULTS WITH DOWN SYNDROME

Vilhena de Mendonça, G., Duarte Pereira, F.
Human Movement Faculty, Lisbon Technical University, Portugal

Introduction
Recently, Guerra, Llorens & Fernhall, (2003) found that sedentary Down-syndrome (DS) individuals had chronotropic-response-index (CRI) values indicative of true chronotropic-incompetence compared to healthy controls. It is not known if there are differences between the CRI of exercise-trained DS adults and that of healthy controls.

The main purposes of this study were to: (1) examine the influence of long-term exercise training on the CRI of DS individuals, and (2) compare the CRI of DS participants with that of healthy controls in response to a graded-exercise-test (GXT) at pre and post-training periods.

**Methods**

Ten male DS participants (33.0 ± 6.6 yo) and nine paired matched controls (32.7 ± 8.0 yo) were included. All DS participants performed a pre- and post-training treadmill GXT. The control group functional capacity was determined at a single occasion for comparison purposes with the DS at baseline and after training. The DS group underwent a 28-week ergometer exercise intervention consisting of two sessions (40 minutes/week, 60-85% peak oxygen uptake - VO2peak).

**Results**

At pre-training period the groups differed (p< 0.05) for: CRI (DS, 0.90 ± 0.09; controls, 1.04 ± 0.07), VO2peak (DS, 22.18 ± 3.80; controls, 25.28 ± 3.83), 51.85 ± 7.67 ml kg-1 min-1, HRpeak DS, 147.30 ± 19.71, controls, 183.66 ± 4.25 bpm, time on the GXT (DS, 12.20 ± 0.56, controls, 15.73 ± 0.71 minutes) and HR increase (IDS, 76.40 ± 0.73, controls, 115.11 ± 3.98 bpm).

Following training, DS participants improved (p< 0.05) their VO2peak and time on the GXT by 27% and 8%, respectively. There were no improvements for CRI or HRpeak following the exercise intervention. However, after training, there were no differences for CRI between DS participants and that initially obtained for controls (DS, 0.98 ± 0.15, controls, 1.04 ± 0.07, p< 0.272).

**Conclusion**

At baseline results show that, DS participants presented a lower chronotropic response to exercise in comparison to controls. Additionally, in opposition to the control group, DS individuals were in the upper limit of pathological CRI values.

Long-term exercise training was effective for eliciting a positive training effect after 28 weeks of continued exercise adherence. On the other hand, neither the CRI nor peak heart rate increased after training. However, opposing to baseline, the post-training CRI values of DS and controls were similar, suggesting a trend for normalization of the chronotropic response. Therefore, despite its inefficacy in eliciting significant intra-group CRI improvements, the exercise regimen attenuated the differences between DS and control participants initially found at baseline. Thus, our results suggest that, despite presenting lower peak HR than controls, exercise-trained DS adults are not chronotropically incompetent.

**CONTRIBUTIONS OF SELECTED FUNDAMENTAL FACTORS TO ATHLETICS PERFORMANCE IN ADULT INDIVIDUALS WITH MENTAL RETARDATION**

**Franciosi, E., Guidetti, L., Gallotta, M., Emerenziani, G., Baldari, C.**

*Istituto Universitario di Scienze Motorie, Italy*

Regular physical activity is encouraged as being important for preventing diseases and promoting physical and emotional well-being for individuals with Mental Retardation (MR) (Fragala-Pinkham et al, 2005; Carmeli et al, 2005), but it is well known that people with MR exhibit poor fitness performance on standard fitness tests (Graham and Reid, 2000). The Aim of this study was to determine the contributions of selected fundamental factors to the athletics performance in adult individuals with MR.

Thirty-two trained athletes with MR (20 males and 12 females, age range 20-45 years, MR levels: 7 Mild, 3 Moderate-Mild, 8 Moderate, 4 Moderate-Severe, 8 Severe and 2 Profound) were recruited. The athletes’ performance was assessed using the official results in an Individual Athletics Championships. The athletes could take part in one or two competitions selected within one of the two ability levels: Level I (60m, 300m, 400m in walking, Standing Long Jump, and Vortex Throw) or Level II (100m, Shot Put, and Long Jump). The fundamental factors included anthropometric measurements (height, weight and %body fat), flexibility assessed by Sit and Reach test, standing balance assessed by Flamingo test, muscular endurance assessed by Push-ups and Sit-ups tests, leg muscular strength assessed by Standing Long Jump test, cardiovascular endurance (VO2max) assessed by Step test and coordination assessed by Timed Get-Up and Go test. Stepwise regression analysis was used to identify the contribution of these selected fundamental factors to athletics performance.

This study showed that in Level I the leg muscular strength and height had significant contributions to 60m (81%), the leg muscular strength and lower %body fat had significant contributions in vortex throw (70%). The coordination, lower %body fat and flexibility had high significant contributions in Standing Long Jump performance (90%). Within Level II, the leg muscular strength and a lower MR level had significant contributions in 100m (85%). Lower weight had high significant correlation in Long Jump scores (P<0.01). Lower age and cardiovascular endurance had high significant contributions in Shot put (98%). It was possible to predict the efficiency of athletics performance in Level I by leg muscular strength, flexibility and coordination. In Level II, cardiovascular endurance and anthropometric measurements were especially important to improve athletes’ performance. All these selected fundamental physical factors should be addressed in athletics training for adult individuals with MR.

**BEHAVIOUR OF TOP FOOTBALL COACHES DURING GAMES**

**Macedo, A., Sequeira, P.**

*High Institute of Science Education, Odivelas, Portugal*

**Introduction**

Research of the behaviour of Football Coaches during a Football games, through observation, is a way to help the development of the coaches education. We think that the context (the game) plays an important role in this matter. The purpose of this study is to find out the differences between male and female coaches behaviour during football games.

**Methods**

Research of the behaviour of Football Coaches during a Football games, through observation, is a way to help the development of the coaches education. We think that the context (the game) plays an important role in this matter. The purpose of this study is to find out the differences between male and female coaches behaviour during football games.
Our sample was composed by 6 Football Coaches (3 male and 3 female), 18 football games from the 2006/2007 and 2007/2008 season. We observed 3 games from each coach. The games were video taped. The results from the observation were based on the total game. We used the SOTA observation system (18 categories).

Results
We compared the behaviour of the Football Coaches during the games by gender. There are significant differences between female coaches in 3 categories: Between male coaches we also found significant differences in 5 categories. Finally, when we compared by gender we found significant differences in only 3 categories.

Discussion/Conclusion
Concerning the results we identified that observation is the behaviour predominant between female coaches during the games. We also identified that female coaches behaviour during the football competitions is less interactive then the males behaviour, but in other hand they give more pressure to their athletes.

EFFECT OF INTERMITTENT NORMOBARIC HYPOXIC EXPOSURE ON PERFORMANCE IN HYPOXIC AND NORMOXIC ENVIRONMENTS

Amon, M., Debevec, T., Keramidas, M., Pisot, R., Simunic, B., Kounalakis, S., Mekjavic, I.
Jozeft Stefan Institute, Jamova 39, ljubljana, SI-1000, Slovenia; and *Science Research Centre, University of Primorska, Garibaldijeva 2, SI-6000 Koper, Slovenia

Introduction: Intermittent hypoxic training has been shown to markedly enhance performance (Hellemans, 1999, Rodriguez et al, 1999, 2000, Harlin, Hellemans, 2007).

Aim: Investigate the effect of intermittent normobaric hypoxic exposure (IHE) on aerobic performance and endurance in hypoxic and normoxic conditions.

Methods: Eighteen male subjects were assigned to either a Control (N=9), or an experimental (IHE, N=9) group. Both groups participated in a 4 week training programme comprising endurance training on a cycle ergometer five days weekly. During each one hour training, the work rate was maintained such that the heart rate was at a level corresponding to that observed at 50% of peak power output (PPO) determined prior to the onset of the training under normoxic conditions. In addition, the experimental group conducted IHE one hour prior to the onset of each training session. During IHE, subjects inspired a hypoxic breathing mixture for 5 min, followed by 3 min of breathing a normoxic mixture. A total of seven such intermittent exposures were conducted. During each hypoxic exposure, the fraction of oxygen in the inspired gas mixture was regulated to maintain a blood oxygen saturation (SaO2) of 80%. Before (PRE), during (PER), upon completion (POST), and 10 days after the training period (AFTER) we evaluated maximal aerobic capacity (VO2max) and PPO under normoxic and hypoxic (FO2=0.12) conditions. We also conducted blood analyses and tests of pulmonary lung function. Endurance performance was reflected in the time the subjects were able to sustain a work rate equivalent to 80% normoxic PPO on a cycle ergometer, under both normoxic and hypoxic conditions.

Results: To maintain SaO2 at 80% during IHE, the FIO2 during IHE was progressively decreased during the course of the training, such that it was 0.12S in week 1, 0.115 in week 2, 0.105 in week 3, and 0.09S in week 4. No significant differences were observed in the normoxic VO2max, endurance performance, pulmonary lung function, and basic haematology in the PRE and POST trials in both groups. There was a significant improvement in the hypoxic VO2max for the IHE group, but not the Control group.

Conclusion: Under the conditions of the prevailing study, IHE may improve performance at altitude, but not at sea level conditions.

THE PHYSIOLOGICAL RESPONSE TO CYCLING-RUNNING SUCCESSION IN YOUNG AND PROFESSIONAL TRIATHLETES

Diaz, V., Peinado, A., Zapico, A., Alvarez, M., Benito, P., Calderon, F., Morencos, E.
Universidad Politécnica de Madrid, Spain

INTRODUCTION
The performance during the running sector of the cycling-running succession in triathlon has been suggested to be helpful in the detection of talented triathletes, even more important than VO2max.1)

Thus, the aim of this study was to compare the cardiorespiratory response during a cycling-running trial of high level triathletes of different age, ir order to establish standards of performance for young triathletes.

MATERIAL AND METHODS
Six professional triathletes (G1, 23.8 ± 5.6 years; 71.2 ± 8.7 kg, 180.0 ± 8.8 cm) belonging to the Spanish National Triathlon Team and nine elite young triathletes (G2, 15.2 ± 0.8 years, 60.8 ± 6.2 kg, 173.7 ± 6.4 cm), selected by the Spanish Triathlon Federation as the best in their category (under 16), participated in the study.

Experimental protocol consisted of two trials performed in random order. In trial 1 (C-R) subjects completed a 30 min cycling at 3.5 W/kg on a cycle ergometer. Immediately after, subjects run 3000m as fast as possible on a 400m track (7.5 laps). Trial 2 (R) consisted of running 3000m as fast as possible. All cardiorespiratory variables were measured with a portable metabolic system (Jaeger Oxycon Mobile) and oxygen costs (OC) was calculated each 400m using the formula of di Prampero (2).

Aim: Investigate the effect of intermittent normobaric hypoxic exposure (IHE) on aerobic performance and endurance in hypoxic and normoxic conditions.

A Student t-test for independent samples was used to examine the differences between the two groups of subjects. Significance was set at p<0.05.

RESULTS
The OC for the G1 subjects was always lower than that for the G2 subjects, but not significantly so; neither were any differences seen between the OC values for the two tests. The G1 subjects took 1.2% longer to complete the running component of the C-R test than to complete the R test (591.2 ± 25.8 vs. 584.6 ± 30.4 s), compared to 3.7% longer for the G2 subjects (669.1 ± 23.8 vs. 645.5 ± 15.8 s). This loss of performance was only significant for the younger subjects.

DISCUSSION
The C-R tests was associated with an acute cardiorespiratory response in the younger athletes (G2) that was not seen in the professionals (G1). This explains the loss of performance seen in these younger competitors in terms of the time to complete the run and the mean speed maintained.

It is possible that the G1 subjects had a better adapted cardiorespiratory response given the longer accumulation of specific training over their sporting lives, certainly it has been shown that training in cycling-running blocks improves performance (3, 4).

Finally, this study provides a performance profile of elite triathletes for the cycling-running trial and shows that young competitors who want to compete at international level must achieve times of under 600 s in the post-cycling running component under the present C-R test conditions.

CONCURRENT ANAEROBIC ASSESSMENT ON 14-15 YEARS- OLD MALE BASKETBALL PLAYERS

Carvalho, H., Figueiredo, A., Vasco, V., Gonçalves, C., Malina, R., Philippaerts, R., Coelho e Silva, M.
Faculty of Sports Sciences and Physical Education, University of Coimbra, Coimbra, Portugal

Basketball, as many team sports, is characterised by short burst, predominantly anaerobic. Despite major children and adolescent participation in game sports, data reporting concurrent anaerobic performances during growing years is lacking. The present study examines the relationship between two field tests and a laboratory test (using a cycle-ergometer) to assess anaerobic performance on male 14-15 years-old basketball players.

The sample included 50 male basketball players (15.2 ± 0.5 years) classified in the stages 4 and 5 of pubic hair. All the subjects took part in a total of 3 tests performed either in the field or in the laboratory: the 30-s Wingate anaerobic test (WanT), 7-sprints test (7-sprT) (Bangsbo, 1994) and 140-m basketball shuttle run (140-mShtT). The latest consists in running a shuttle run from a baseline to marks at 5, 8, 14, 22, 28 and 30 m. Photoelectric cells were used to measure total time. Relations between the anaerobic tests were evaluated using Pearson correlations. Significance level was set at p<0.05.

The best sprint of the 7-sprint test showed the highest correlation with the 140-mShtT (r=+0.68, p=0.01). Results also showed modest correlations between field and laboratory tests, specially when WanT peak power (PP) and mean power (MP) were expressed in their absolute values. The association between 140-mShtT and the laboratory test increased when PP and MP were expressed per unit of body mass (r=+0.71, p=0.01, for PP; r=+0.71, p=0.01, for MP).

The 7-sprint test is modestly correlated with the 140-meter shuttle run and poorly related to Wingate test. Overlapping variance between field test and Wingate outputs are no more than about 50% for the 140-meter run. The magnitude of the association increases while expressing mean and peak anaerobic power per unit of body mass. The contribution of concurrent anaerobic test on the discriminant analysis of basketball players per competitive level and age-group, controlling for maturational status and past sport experience would be of interest.

THE GAME INDICATORS ASSOCIATED WITH TEAM SUCCESS IN THE LAST TEN MINUTES OF BALANCED HANDBALL MATCHES

Teles, N., Volossovitch, A.
Technical University of Lisbon, Portugal

Introduction
Sport game experts identify the last minutes of close matches as their critical moment (Bar-Eli, et al, 1992; Sampaio, et al, 2004). Thus, the reliable analysis of performance of this game period helps the coach to recognize the players’ actions and behaviour patterns that related to team’s success. The purpose of this study was to identify the set of relevant game indicators which distinguish winning from losing teams in ten last minutes of balanced matches.

Methods
The sample consisted of 16 balanced semi-finals and final matches from the 2003, 2005, and 2007-Men’s World Championships, as well as 2004 and 2006-Men’s European Championships of Handball (drawn and extended matches were not considered). The point differences in last ten-minute period were always below 5 points. 55 performance indicators were registered per ball possession in each match.

The test of Mann-Whitney was used to identify significant differences between winning and losing teams in last ten minutes in observed matches.

Results
It was noted that frequencies of the most of performance indicators were similar for winning and losing teams. The significant differences between winning and losing teams were found in nine variables that could be associated with the final result of the matches: break through goals (p=0.013); goals scored in position play (p=0.01); positional play shots efficiency (p=0.003); goals scored in fast break (p=0.045); fast break frequency (p=0.001); fast break efficiency (p=0.001); attack duration (p=0.02); goalkeeper defences (p=0.024); goalkeeper efficiency (p=0.022).

Discussion
As expected, the findings of this study revealed the more efficient play of winning teams in positional attack and goalkeeper actions during the last ten minute of match. It was registered that successful teams had longer ball possession comparatively with defeated teams. The losing teams, trying to recover from disadvantage, used more attempts and scored more goals in fast breaks.

Evidently, the summarized data are not sufficiently informative for explaining the team’s success or failure in the balanced games, but this data can be useful for describe the play profile of the team. In any case it’s necessary to consider the temporal and score evolution in the match, as well as opposition relationship between playing teams.

DRIBBLING AS PREDICTOR OF FUTURE SOCCER PERFORMANCE

Huijgen, B., Elferink-Gemser, M., Visscher, C.
University Medical Center Groningen, Netherlands

To reach the top in soccer, technical skills are of extreme importance. The current study focuses on the development of dribbling with quick changes of direction, since this is recognized as a central component in the development of professional players (Malina et al. 2005; Reilly et al. 2000). To predict long-term success within a group of talented youth soccer players, longitudinal tracking is needed. The goal of the present study is to reveal whether the technical performance characteristics of dribbling and the factors underlying this technical skill have power for predicting future professional soccer players.

A total of 134 talented soccer players from soccer schools in the Netherlands age 14-18 were tested, 237 measurements were performed. The players tested are currently 20 years or older and are classified into their current playing level: professional (N=31), semi-professional (N=54) or non-professional (N=54) players. The Shuttle Sprint and Dribble Test was used to measure the development of dribbling performance in a longitudinal study over 5 years. The test consisted of a maximal sprint of 30 m while dribbling a soccer ball (Lemmink et al. 2004). The 30 m sprint has three 180° turns, measuring the acceleration of soccer players. Anthropometrics (height, weight, and body fat percentage), and training characteristics were assessed. Longitudinal changes in dribbling were investigated using the linear-mixed model procedure in SPSS.

The fixed part of the multilevel model contains a different intercept term for the current playing level (semi-professionals + 0.07 seconds and non-professionals + 0.17 seconds compared to professionals). The multilevel age-model showed better performance of the current professional players compared to the current lower level players at age 15, 16 and 17 on the Shuttle Dribble test (p < 0.05). The age-model was significantly improved by including lean body mass and total practice hours per week, both having a positive effect on dribbling performance.

Although soccer performance can be divided into many multidimensional performance characteristics (Elferink-Gemser et al., 2004), the current results showed that dribbling performance in youth can be an useful tool for identifying the best players for the future. Current professional players outscored current semi- and non-professional players in dribbling during adolescence, especially from age 15-17. More lean body mass and extra practice hours positively influence dribbling performance. The Shuttle Dribble test illustrated to be a good predictor for future playing level.

EFFECTS OF PILATES TRAINING ON BLOOD MARKERS OF OXIDATIVE STRESS

Iggnjatovic, A., Radovanovic, D., Dondur, S.

Faculty of Pedagogy, University of Kragujevac; Serbia, Serbia and Montenegro

INTRODUCTION: Muscular exercise increased production of free radicals and other forms of reactive oxygen species. The risk of oxidative stress with exercise depends on exercise intensity and the participant's state of training. Pilates is a system of over 500 controlled exercises that engage the mind and condition the total body. It is a balanced blend of strength and flexibility training that improves posture, reduces stress and creates long, lean muscles without bulking up.

AIM: This study examined the effects of 12 weeks pilates training on selected markers of oxidative stress in young women.

METHODS: Seven young women (mean±SD: age 24.7±3.7 years, body height 1.61±0.5 m, body weight 54.9±8.3 kg, body fat 11.1±5.2%) participated in the study. Blood samples, collected at rest before and after twelve weeks pilates training, were analyzed for the determination of selected markers of oxidative stress (lipid peroxidation byproduct malondialdehyde MDA, enzyme catalase CAT, carbonyl and sulphydryl group assay for determination of modified proteins and total antioxidant status TAS). The results were statistically evaluated by the Wilcoxon Signed Ranks Test.

RESULTS: An important finding in present investigation is that CAT increased significantly after 12 weeks (plasma CAT median 13.4 IU/L-1 pre vs. 34.56 IU/L-1 post, p<0.05). There were no significant changes in erythrocyte MDA (median 13.22 µmol/L-1 pre vs. 14.42 µmol/L-1 post, p>0.05), sulphydryl group (median 281.46 µmol/L-1 pre vs. 242.64 µmol/L-1 post, p>0.05), carbonyl group (median 1.2 µmol/g-1 of proteins pre vs. 1.31 µmol/g-1 of proteins post, p>0.05), and TAS (median 69.1% pre vs. 64.7% post, p>0.05).

CONCLUSIONS: This data suggest that 12 weeks pilates training increase the activities of CAT. Also, it can be concluded that pilates training program did not have other effects on oxidative stress levels in young women.

CONTROL AND MONITORING IN TRIATHLON: A STUDY OF THE ATHLETE'S SUBJECTIVE SELF PERCEPTION AND LOAD TRAINING

Leite, G., Borin, J., Amauri, S., Andries Junior, O.

University Nine of July, University Methodist of Piracicaba, Brazilian Confederation of Triathlon, State University of Campinas, Brazil

Monitoring load training and tiredness subjective self perception, as well as effort taken, is crucial at the training process in many different sports. In triathlon studies which relate prescribed stimuli and subjective answer referred by the athlete are not common. The main objective of this study was to verify the relationship among indicators of training load and tiredness subjective self perception in triathlon. Triathlon - long distance, category of athletes aged from 25 to 29 years old (the athlete was 27 years old, 181 cm, 74.6 kg, Body Fat percentage 8.8) 2007 Brazilian's male champion training was evaluated during five weeks - 69 sessions of training, at the following variables: daily training duration in minutes, tiredness subjective self perception throughout a scale adapted from Borg (1982) and effort taken during every single session; and, following Foster (1998) proposal, intensity, media of weekly load, weekly total load, monotony, and strain were quantified. In order to analyze variation existence, and data relationship, descriptive measures of centrality and dispersion, and Pearson's correlation coefficient (r) (p<0.05) were used. Principal results point out to a variation of the daily training duration quantified in minutes (167.1±59.3 min), and tiredness self perception measures before (11.6±0.8), and after (13.3±0.7) daily training. Variables quantified by Foster's (1998) method also presented a variation during the period, as intensity (3.8±0.2), media of weekly load (619±93.6), and weekly total load (4335±655), monotony (2.15±0.4), and strain (9316±2070). It is highlighted that the correlation coefficient of intensity and self perception of tiredness before and after training, respectively r = 0.93 and r = 0.99, for p<0.05, demonstrates that tiredness after the most intense trainings had risen. To monitor tiredness subjective self perception seems to help the understanding of the relationship stimuli/pause of the analyzed training, as well as being a helper on identifying alteration at intensity and load variables, important indicators to not have other effects on oxidative stress levels in young women.

A FIELD TEST TO EXHAUSTION FOR VO2MAX DETERMINATION OF SOCCER PLAYERS

Gatterer, H., Faulhaber, M., Burtscher, M.

University Innsbruck, Austria

The maximum oxygen uptake (VO2max) is one of the main variables to evaluate the cardio-respiratory fitness of an individual (1). In many sports a highly developed VO2max is prerequisite for good performance. This was also shown in soccer, where studies have demonstrated that player with a higher VO2max cover greater distances, complete more sprints, chose an enhanced average work intensity, and have an enhanced average aerobic energy contribution during match play (2,3). Because the determination of VO2max of an entire team is very time and equipment expensive, its regular use is rather uncommon. Therefore, the aim of this study was to evaluate the validity and the practicability of a 600 m run to exhaustion for VO2max testing of soccer players.

Six healthy young male soccer players (age: 18.2±0.4years, height: 180.8±6.8cm, weight: 72.2±7.6kg) of the national youth training centre participated in the study. Each subject performed a field test to exhaustion (after warm up subjects run two laps on a soccer pitch. The speed was continuously increased by means of self-assessment (0.5 lap at 50%, 0.5 lap at 70%, 0.5 lap at 90% and 0.5 lap at 100% of self estimated maximal performance capacity). If exhaustion was not achieved, subjects had to continue running maximally until complete fatigue and an incremental treadmill test (after 10 minutes at 6 km/h, the test started with a speed of 9 km/h (inclination 1%). The velocity was increased by 1 km/h every 1 minute until exhaustion). During each test oxygen uptake (VO2), ventilation (VE) and heart rate (HR), via chest belt, were measured with a portable spirametric-telemetric device (Oxycon mobile). In the 3rd minute after cessation of work, blood lactate concentrations (La) were determined.

There couldn't be detected any significant differences between the two tests except for the Lamax (p=0.001). During the tests the subjects achieved a VO2max of 58.3±3.7 and 57.5±3.7 ml/min/kg, a VEmax of 143.2±23.7 and 138±17.3 l/min, a HRmax of 187±4 and 190±6 b/min and a Lamax of 10.7±1.5 and 7.9±1.6 mmol/l for the field and the treadmill test.

The results indicate that a 600 m run to exhaustion could be adequate for VO2max determination of soccer players. The recorded small intra-individual differences could entirely be explained by the day-to-day variability of VO2max determination and the measurement variability due to the device. The higher values of La during the field test can be explained by the different protocols. During the field test the maximum intensity is reached faster and held for a longer period of time so that anaerobic processes were more stressed. Even if the test results are very promising more work has to be done to draw firm conclusions. However, if confirmed, this test could be a simple tool for exercise testing in soccer.

AMERICAN WOMEN’S COLLEGE WATER POLO: A TECHNICAL AND TACTICAL ANALYSIS OF THE CENTRE FORWARD ROLE

Lupo, C., Tessitore, A., King, B., Capranica, L.
University Institute of Motor Sciences, Italy

Introduction
Women’s water polo became an Olympic sport at the 2000 Sydney Olympic Games. Despite its short history, women’s water polo evolved quickly in many countries of Europe, Australia, and United States. At present, women’s water polo has accomplished a huge evolution where players’ technical and tactical abilities need to be specific according to the different roles. Recently, the analysis of elite men’s water polo matches showed that centre forwards perform intense and all-out actions (Smith, 1998), determining the majority of exclusion faults during man-up actions, and the highest number of goals (Lupo et al., 2007). Since there is a lack of information regarding women’s water polo, the aim of this study was to analyze the technical and tactical aspects of women’s water polo centre forwards during American college matches.

Methods
A notational analysis of 7 water-polo matches played during the NCAA 2007 championship was performed from DVD recordings. The actions were classified as even-play, counter attack, and woman-up play (including penalties) situations, considering their relative goal outcome. Furthermore, during even-play, the technical and tactical aspects of the centre forwards were analyzed according to the occurrence of the following indicators: goal, shot with no goal (out, save, posts, goalkeeper and field player bouncing, and corner), exclusion achieved (including penalties), steal ball, bad pass to and from the centre, and offensive faults. To assess the test-retest reliability, prior to the study the observer scored a single match twice, each observation separated by 7 days, showing no difference between observations.

Results
The frequency of occurrence of even-play, counter attack, and woman-up play actions was 80.3±5.3%, 6.2±4.4%, and 13.5±4.7%, respectively. The relative picture for goal scoring was 42.4±22.9%, 9.9±9.9%, and 47.8±24.8%, respectively. The centre forwards concluded 45.2±9.6% of the even-play actions. Only regarding the centre forward indicators, goal=10.6±6.9%, shot with no goal=18.6±8.1%, exclusion achieved (including penalties)=24.0±7.1%, steal ball=15.9±7.5%, bad pass to the centre forwarder=12.3±8.7%, bad pass from the centre forwarder=15.2±2.5%, and offensive fault=17.1±9.8%. Centre forwards also determined 63.2±22.1% of the exclusion (and penalty) faults.

Conclusions
The present data show that women’s American College water polo is substantially influenced by the centre forward role, especially for the achieving of several exclusion faults from which follow woman-up actions, the most advantageous playing situation to score a goal.

FIELD TESTS OF THE FLEXIBILITY OF LOWER EXTREMITY: RELIABILITY STUDY

Bozic, P., Pazin, N., Planic, N., Berjan, B., Cuk, I.
Faculty of Sport and Physical Education, Belgrade University, Serbia, Serbia and Montenegro

Objectives:
Pre-seasonal flexibility testing has been commonly used to identify intrinsic risk factors of sport injury, as well as the capacity for the efficient movement performance. Unlike the laboratory tests of flexibility, the reliability of the field tests of flexibility has not been evaluated yet. The purpose of this study was (i) to evaluate the reliability and relationship among the most commonly applied field tests that was designed to assess flexibility of lower extremities, and (ii) to examine their concurrent validity.

Methods:
Physical education students (n=84) were familiarized and tested by two raters on three occasions (one familiarization and two testing sessions) performed one week apart in order to establish the intra-trial and test-retest reliability of the selected tests assessed by different measurement methods. In addition, one out of five participants was tested simultaneously both by means of a 3D kinematics analysis system and by means of standard field devices (kinantropometry, ruler and protractor) in order to assess the concurrent validity. The following tests were evaluated: Leg Raise in a Supine Position, Hip Abduction Test, Single-Legged Knee Bend, Sideward Leg Splits, Sit and Reach, Sideways Leg Splits and Lengthwise Leg Splits.

Results:
All tests demonstrated a high intra-trial reliability (Intraclass correlation coefficient, ICC=0.88-0.97). The corresponding within-subject variation (CV) ranged between 1.2 and 3.5%. A one-way ANOVA revealed non-significant differences among three trials. Test-retest reliability proved to be moderate to excellent (ICC=0.57-0.94, CV=2.0-6.7%) and the differences between the test and rated were below the significant level (p>0.05). Relationship among the tests was moderate to strong (r=0.44-0.94). When compared with objectively measured by the 3D system, the concurrent validity of field methods for estimation of flexibility was high (r=0.84-0.99).

Conclusion:
The findings suggest that the simple and effective field tests of flexibility of lower extremity based on using inexpensive equipment could be both reliable and valid. Therefore, the findings support their use as a pre-season screening tools for athletes. The obtained strong relationships among the tests also suggest that the routinely applied test batteries could be based on very few tests of the flexibility of lower extremity.

PHYSIOLOGICAL CHARACTERISTICS OF ELITE BRITISH JUNIOR AND SENIOR RUGBY LEAGUE PLAYERS

Sykes, D., Twist, C., Foster, C.

University of Chester, United Kingdom

Whilest studies have previously reported physiological characteristics for Australian sub-elite junior and senior rugby league [RL] players (Gabbett, 2002), no study to date has investigated whether differences exist between elite junior and senior players. Therefore, the aim of this study was to investigate the physiological characteristics of elite British junior and senior RL players. A total of 254 elite junior [u13, n=27; u14, n=49; u15, n=78; u16, n=53] and senior [n=47] players from a professional RL club attended one field testing session at the start of pre-season. Players were categorised as forwards (n=96), backs (n=87) or pivots (n=71). Anthropometric measurements included standing stretch stature, body mass (BM) and the sum of four skinfolds (SKF). In addition, 0-10 m static acceleration and a multi-stage fitness test (MSFT) were performed in an indoor venue on a non-slip surface. Momentum over 0-10 m was also calculated as the product of velocity and BM. Data were analysed using two-way [position x age] ANOVA with Tukey’s post hoc test. Standing stretch stature, BM and SKF were measured at angular velocities of 90°.s⁻¹ (1.57 rad.s⁻¹). Sprint performance (5 meters), agility (T-test), kick performance [Professional Sports Radar] and vertical jump performance (squat jump and countermovement jump; Ergojump device) were also evaluated. Descriptive statistics were determined for the three age levels considered. Coefficient of correlation was calculated by Pearson product-moment correlation coefficient. The level of significance was set at 5%. SPSS 15.0 was used in all analyses.

Results: (1) We observed an increase of peak torque of knee extensor muscles of the dominant leg with age [U-14: 165.5±33.8; U-16: 197.8±28.6 and U-18: 208.5±37.2 N/m]. (2) Hamstring/quadriceps ratios of the dominant leg were U-14: 49.5±8.5, U-16: 51.5±8.7 and U-18: 50.8±8.4%. (3) Pearson correlation test showed a positive and low correlation between the peak torque of the extensor muscles and the kicking ball velocity (r=0.22, p=0.03), and 5 meters speed (r=0.27, p<0.001). A positive and moderate correlation was observed between the peak torque of the extensor muscles and agility (r=0.40, p<0.001), squat jump (r=0.44, p<0.001) and countermovement jump (r=0.40, p<0.001).

Conclusions: These results provide evidence that peak torque of the extensor muscles of the knee is associated with agility and vertical jump performance.
RELATIONSHIP BETWEEN TETHERED SWIMMING FORCES AND FRONT CRAWL AND BUTTERFLY PERFORMANCES

Morouço, P., Soares, S., Vilas-Boas, J.P., Fernandes, R.
*University of Porto, Faculty of Sport, Porto, Portugal

A review of the specialized literature about tethered swimming shows that it is scarce the number of studies conducted over other swimming techniques than front crawl. Additionally, most studies were developed using partially tethered swimming. Except Magel (1970), no butterfly stroke characterization was found. Yeater et al. (1981) studied the relationship between mean tethered force and mean velocity for front crawl, backstroke and breaststroke using fully tethered swimming. Those authors got a positive correlation between mean force and velocity for front crawl and no evidences were shown for the same relation for breaststroke and backstroke. The purpose of the present study was to correlate the mean force obtained in a 30 s maximum tethered swimming test with the mean velocity obtained during a 50 m maximum intensity front crawl and butterfly swimming test. Subjects were eleven male volunteers of the Portuguese National Absolute Team.

Six swimmers (179.3 ± 12.1 cm and 73.6 ± 6.2 kg) performed a 50m front crawl swimming test at maximal intensity, and other five swimmers (179.1 ± 7.37 cm and 74.0 ± 9.47 kg) performed butterfly stroke. All swimmers were specialists on the technique swam. Tests were performed on a long course swimming pool. For the 30 s tethered swimming test, swimmers were attached by a non-elastic cable to a strain-gauge (Globus, Italy).

Mean velocity values obtained for front crawl was 1.86 ± 0.06 m.s-1 and 1.78 ± 0.09 m.s-1 for butterfly stroke. Average force assessed was 1218 ± 13.71 N for front crawl and 103.5 ± 21.8 N for butterfly. Complementarily, a positive and significant correlation was found between mean tethered swimming force and mean velocity, either for front crawl ($r = 0.922$, $p < 0.01$), as well as for butterfly technique ($r = 0.933$, $p < 0.01$). Obtained data seems to indicate the possibility of the mean force obtained through a 30 s fully tethered swimming test predict the mean velocity correspondent to a 50m front crawl ($r = 0.004$ tethered force + 1.318), corroborating the findings of Yeater et al. (1981) and butterfly swimming events ($r = 0.004$ tethered force + 1.358).

INTRA AND INTER-EXAMINER RELIABILITY OF THE ADAPTED PHYSICAL ACTIVITY BED FOR EVALUATION AND TRAINING OF TERMINAL SHOULDER FLEXION STRENGTH

Carvalho, L., Carneiro, R., Azevedo, D., Andrade, G.
*Universidade Federal de Minas Gerais, *Pontifícia Universidade Católica de Minas Gerais, Brazil

INTRODUCTION: The forward shoulder posture is related to the Impingement Syndrome because it narrows the subacromial space. People with this posture pattern benefit from the terminal shoulder flexion exercise. Objective: To evaluate the intra and inter-examiner reliability of the isometric test for terminal shoulder flexion maximum strength.

MATERIALS AND METHODS: Subjects: 9 males and 10 females, age range 20.8 ± 1.8, healthy. Materials: Adapted physical therapy bed with a guide arm with vertical handles and a dynamometer support. Procedures: Subjects performed warm-up exercises consisting of 15 minutes.

RESULTS: Intra-examiner reliability of the test was .98 ($p<0.05$) and inter-examiner reliability was .96 ($p<0.05$).

CONCLUSION: The isometric test for terminal shoulder flexion in prone position using these equipments and methods shows excellent results for both intra and inter-examiner reliability in a sample of healthy young individuals. This test may be used both as a form of physical evaluation and training control of isometric terminal shoulder flexion.

PHYSIOLOGICAL PROFILES OF YOUNG ELITE ATHLETES OF DIFFERENT DISCIPLINES

Haegle, M., Sperlich, B., Nitsch, S., Zinner, C., Wahl, P., Suhr, F., de Mareés, M., Engelmeyer, E., Mester, J.
German Sport University, Cologne, Germany

INTRODUCTION: Much is known about the physiological demands, which are needed to be competitive in endurance sports at elite level. Although there is accordance about the importance of a basic endurance ability in many sports, there is much less data available which describe the physiological profiles of athletes of team sports or sports with mainly technical character (e.g. Judo, Fencing, Basketball). Because of increased numbers of competitions and training sessions, in these sports a high endurance level is required as well. Not only competing but rather a high ability to recover is essential to be competitive at international level. Furthermore the risk of injuries is reduced while continuous attention can be maintained during activity and immune system is stabilized. Due to this lack of data, the capturing of physiological profiles of athletes of different sports is essential to develop training strategies and to filter weaknesses in performance. Therefore reliable parameters for aerobic endurance capacity (lact threshold, VO2peak) were measured.
the current literature only 10.8% of our tested athletes barely strike this endurance capacity level. Due to the fact that coaches in technical or team related sports have limited time periods to develop endurance capacity, time saving strategies like high intensity training should be accounted for training regimes.

**DISCUSSION:** Considering there exist different test protocols to detect VO2peak, a mean value of 60ml/kg/min is the average found in published literature of international competing athletes. According to this literature only 10.8% of our tested athletes barely strike this endurance capacity level in comparison to international successful athletes. This level of 4.0 m/s was achieved by 27% of the athletes in this investigation. Due to the fact that coaches in technical or team related sports have limited time periods to develop endurance capacity, time saving strategies like high intensity training should be accounted for training regimes.

**COMPARISON OF AEROBIC ENDURANCE CAPACITY IN MEMBERS OF SPECIAL FORCES AND SOCCER PROFESSIONALS**

Haegele, M., Sperlich, B., Nitsch, S., Zinner, C., Wahl, P., Suhr, F., de Mareés, M., Engelmeier, E., Mester, J.

*German Sport University Cologne, Germany*

**INTRODUCTION:** Although members of special forces of Military or Police have eminent duties and responsibilities there is few knowledge of the physiological demands of that profession. Although all members of these forces should be regarded as professional athletes, much of the training regime is not specific with regard to their goals and is influenced more on practical experiences than on scientific findings. In comparison, soccer players at elite level have several coaches being responsible for different physiological components (e.g. strength, endurance). Furthermore, possibilities to ensure a fast recovery and medical services are available to prevent injuries. On the other hand members of special forces are struggling with injuries in many cases. These are mostly fatigue related and consequences of physiological overload. To avoid fatigue related injuries, a high endurance capacity level will be preventive. Due to the fact, that soccer training as well as training for member of special forces include technical and tactical aspects, the time available for endurance training is limited in both of these groups. The aim of this study was to define the aerobic endurance capacity of the members of a special forces and of professional soccer players.

**METHOD:** 38 male volunteers of Police special force (mean value for height and weight: 183.6±5.6cm, 82.5±7.3kg) and 22 male professional soccer players (184.3±6.0, 81.2±6.1) were tested. In order to detect the thresholds at 2 and 4 mmol/l (V2, V4) on a treadmill, all subjects performed a step test (start: 2.8m/s, increase: 0.4m/s, duration of step: 5min, incline: 1%). Oxygen uptake (VO2) and Respiratory Exchange Ratio (RER) was recorded by an open spirographic device (ZAN 600).

**RESULTS:** Mean values for velocities at lactic concentrations of 2 and 4 mmol/l, as well as VO2peak were 3.4±0.3m/s, 3.8±0.2m/s and 56.7±4.8ml/kg/min. Maximal values during the step test were 3.7m/s, 4.2m/s and 65.4ml/kg/min. Mean values for soccer players were 3.3±0.5m/s, 3.9±0.3m/s and 54.7±7.1ml/kg/min. Maximal values were 3.7m/s, 4.2m/s and 65.3ml/kg/min.

**DISCUSSION:** The results show similar data for V2, V4 and VO2peak for the police men as well as for the soccer players although the training concept is different. In soccer training normally a volume oriented training is chosen whereas in special forces a high intensity training (strength & endurance training) is exercised in many situations. Although the training in special forces includes other time consuming aspects than physical training such as mission tactics and simulation, handling weapons and individual tasks (e.g. first aid), a high intensive training shows similar results than professionally organised training with soccer players. The collected data help to understand the physiological demands in very different situations such as police tasks and soccer and to find background variables for performance.

**LACTATE AND VO2-KINETICS DURING TRAINING AND MATCH IN TABLE TENNIS: CONSEQUENCES FOR EXERCISE**

*German Sport University Cologne, Germany*

Table tennis (TT) has developed to a global sport. Especially young TT-players face an increasing amount of training, matches & travelling. From this focus, a high endurance level plays a beneficial role for fast recovery and increased concentration during stress situation. For developing endurance performance it is vital to quantify the metabolic demands during TT training and matches in order to develop strategies for the training process. The mere analysis of lactate concentration (Lac) before and after training will not quantify the energetic demands during a complete training session or match. Close monitoring of Lac, heart rate (HR) and oxygen uptake (VO2) are favourable. The aim of the study was to determine metabolic energy demands during intensive and moderate training as well as during match in order to develop strategies for training process. **METHOD:** Lac, HR, VO2 and ratings of perceived exertion (RPE) in 8 juvenile subjects (15±1yrs, 71.4±10.9kg, 182±9cm) were measured during three special training sessions (TS, 82±13±4:09 min) and during an international match simulation (15:13±4:09 min) with three sets. The three TS were planned by a German Junior National Coach with either a technical/moderate emphasis or high intensive TT-specific stress. VO2 was registered continuously with portable spirographs (K4B2 & Metamax) calibrated prior to every single test. HR was recorded online every 5s. Lac-concentration was analysed amperometric-enzymatically. Additionally the subjects were asked to rate their perceived exertion. Lac and RPE were collected closely every 1-3 minutes. **RESULTS:** The average Lac concentration during the high workload reached 2.06±1.10 mmol/l. Mean heart rate was measured with 127.4±18.6 B/min and mean relative VO2 with 21.6±8.7ml/min/kg. Mean RPE values were noted 16±2±2.3 on the BORG’s scale. Peak values in TS reached 168.0 B/min and 44.1ml/min/kg as well as BORG 20. The peak values were achieved after a special drill without breaks playing 200 balls at maximum speed. During less intense TS average values for Lac (0.98±0.16 mmol/l), HR (125.2±40.2 B/min) and mean relative VO2 with 21.1±8.7ml/min/kg. Mean RPE values were noted 16.2±2.3 on the BORG’s scale. Peak values were achieved after special drill without breaks playing 200 balls at maximum speed. During less intense TS average values for Lac (0.98±0.16 mmol/l), HR (125.2±40.2 B/min) and mean relative VO2 with 21.1±8.7ml/min/kg. Mean RPE values were noted 16.2±2.3 on the BORG’s scale. The collected data help to understand the physiological demands in very different situations such as police tasks and soccer and to find background variables for performance.
MAXIMAL VOLUNTARY ISOMETRIC FORCE IS LOWER DURING BILATERAL COMPARED TO UNILATERAL QUADRICEPS CONTRACTIONS

Matkowski, B., Martin, A., Lepers, R.
INSERM U887 Motricite Plasticite, France

Introduction
A reduction in force produced by homonymous muscle during bilateral (BI) maximal voluntary contractions (MVC) compared with the sum of unilateral (UNI) MVC forces has been previously described. This phenomenon, which is known as the bilateral deficit, has not been found in all instances (see Howard and Enoka 1991, Kawakami et al. 1995 vs. Jakobi and Cafarelli 1998). However, the contribution of each leg has never been quantified using independent strain gauges during BI MVC. The purpose of this study was to compare the isometric MVC force of the knee extensor muscles between unilateral and bilateral contractions using a system equipped with two separate strain gauges.

Methods
Twenty physically active men (26.5 ± 4.5 years) volunteered to participate in this study. They were placed in the seated position on a leg extension machine with the hips at 90° and the knee flexed at 70°. Subjects performed several MVC of the knee extensor muscles in different conditions (3 trials/condition): unilateral MVC with the right (MVC RUNI) and left leg (MVC LUNI) and bilateral MVC. MVC RBI and MVC LBI corresponded respectively to the MVC force of the right and left legs during bilateral contractions. The interpolated twitch technique was used during MVC to quantify maximal voluntary activation level (VAL).

Results
MVC RBI (401.9 ± 76.4 N) was significantly lower (P<0.01) than MVC RUNI (418.2 ± 77.9 N), in the same way, MVC LBI (399.4 ± 87.3 N) was significantly lower (P<0.01) than MVC LUNI (421.5 ± 78.1 N). VAL was not significantly different between UNI and BI conditions (P=0.12 for MVC RUNI; 91.6 ± 4.9 % for MVC RBI; 90.2 ± 7.3 % for MVC LUNI and 90.1 ± 6.4 % for MVC LBI).

Discussion
These results showed that absolute MVC force of the knee extensor muscles depends on the mode of contraction, i.e. maximal force is lower for BI MVC compared to UNI MVC. These findings confirm the results of previous studies (e.g. Howard and Enoka 1991, Kawakami et al. 1995), i.e., lower maximal force produced by homonymous muscle during BI MVC compared with the sum of UNI MVC. Since maximal voluntary activation level was similar between UNI and BI conditions, it is suggested that bilateral deficit was not due to neural mechanisms. Further studies are needed to clarify the physiological/biomechanical mechanisms underlying bilateral deficit.

EFFECTS OF WHOLE BODY VIBRATION ON MAXIMAL STRENGTH AND POWER DEPENDING ON INPUT FREQUENCY

Reifberger, A., Müller, E.
University of Salzburg, Austria

The human body reacts to external vibration with muscle tuning as a damping mechanism to avoid a resonance catastrophe. An induced vibration of a muscle near to the individual natural frequency (INF) leads to an increasing muscle activity (Wakeling, Nigg & Rozitis, 2002). Therefore, it is assumed that vibration training at the INF will result in an increase of strength. The purpose of the study was to evaluate whether mechanical vibration induced with the INF leads to a higher increase in maximal strength and power compared to vibration with a general frequency of 30 Hz. 30 sport students took part in the study, 17 men (26.3 ± 3.8years, 78.3 ± 6.9kg) and 13 women (21.7 ± 1.7years, 60.2 ± 5.6kg). At different frequencies (vibration plate, Galileo 2000) the INF was assessed from m. rectus femoris by using an accelerometer. The INF was defined as the frequency where the amplitude of the acceleration is lowest. Two intervention groups performed vibration training, three times a week for a time interval of 7 weeks. The subjects had to stand in a static position with a knee angle of 140 degrees (8 series of 60-120 seconds). A third group served as a control group (no training). The vibration frequency of group one was adjusted to the INF. Group two practised with a general frequency at 30 Hz which was different to the INF. Before and after the training period, explosive power and isometric strength of the legs were measured. It was expected that group one shows a higher enhancement in strength parameters in comparison with group two. One way ANOVAs of the differences between the pre and post test values have been calculated for each parameter. The analyses show significant differences between the groups for maximum strength of the left leg (F=7.577, p<0.003, etaf=0.367) and right leg (F=3.705, p=0.041, etaf=0.252) and for explosive power of the right leg (F=6.207, p=0.007, etaf=0.361). Post hoc tests indicate that only the control group differs significantly from the intervention groups. The results are not in line with the assumption that vibration training at the INF leads to the highest increase in maximum strength and explosive power. Reasons for this unexpected result may be due to methodological and technical limitations and will be discussed.

COMPARISON OF POWER OUTPUT MEASUREMENTS DURING ERGOMETER AND ON-WATER ROWING

Vogler, A., Rice, A.
Australian Institute of Sport, School of Education, Flinders University, Australia

Introduction
Physiological responses to rowing training are usually assessed by laboratory-based incremental tests conducted on rowing ergometers, although several on-water protocols have been reported (1, 2). These investigations used custom-designed equipment to measure on-water power output (2), but did not measure oxygen consumption (VO2). This study evaluated commercially available power and VO2 measurement devices for on-water testing applications and compared results between ergometer and on-water tests using matched protocols.
Methods

Seven male rowers (mean age 20.4 years, s=2.0; VO2max 5.61 L min⁻¹, s=0.47) completed incremental tests on a rowing ergometer (Concept2 Model D, Morrisville, USA) and in a single scull (Sykes Racing, Geelong, Australia) instrumented with a WEBA Sport Rower Expert Light biomechanics system (WEBA, Wien, Austria). Ergometer (ERG) and on-water (OW) tests both comprised five submaximal workloads and one maximal performance trial each of 4 min duration; tests were completed in a randomised order. Average power output during each workload was measured by the Concept2 work monitor unit and WEBA during ERG and OW tests, respectively. VO2 (Cortex MetaMax 3B, Leipzig, Germany) was measured using the average from steady-state conditions achieved during the final 2 min of each workload. VO2-power relationships were established for ERG and OW conditions, thereby permitting comparisons between data from both power measurement devices at each workload based on VO2 values matched between tests.

Results

Strong VO2-power relationships were obtained during ERG (r=0.96) and OW (r=0.94) tests. ERG and OW VO2 values predicted from the same five submaximal power output references (140-280 W) were not significantly different and displayed a strong correlation between tests (r=0.91). However, mean VO2 values were consistently higher during the OW test (3.04-4.88 L min⁻¹) compared to the corresponding ERG data (2.84-4.48 L min⁻¹). These differences were eliminated (+/-0.02 L min⁻¹) when power output comparisons were offset, normalised mean VO2 data indicated that the reference ERG power outputs between 140 and 280 W have equivalent OW power outputs between 128 W and 277 W. During maximal exercise, OW power output was significantly lower (8.0%, P=0.04) and the corresponding VO2 1.2% lower.

Conclusions

Incremental rowing tests that include power output and VO2 data can be completed on-water using commercially available measurement devices. Although the resulting VO2-power relationship was not significantly different between tests; compared to Concept2 ergometers, the WEBAs may under-represent power output during submaximal and maximal rowing.

COMPARISON OF FOREHAND RECEIVING ABILITY OF NATIONAL-LEVEL TO SENIOR HIGH SCHOOL-LEVEL MALE TABLE TENNIS PLAYERS

Yite, L., Tseng, WP.
National Changhua University of Education, Taiwan

The receiving ability is one of main factors of anticipating the other initiative to win in a table tennis match. The strength of receiving is directly concerned with bringing skills and tactics into a play.

Purpose: To give an idea of advancing receiving ability, a new procedure to assess forehand receiving performance of male table tennis player at different level in simulated conditions was employed in this study. Method: 32 male players representing two different skill levels volunteered in this study. Ten of them are at national-level, while 20 belong to senior high school champion team in 2007 National High School Games. The protocol consists of 5 tests, including basic control, reflection, agility, judgment and match-like condition. Every test is composed of 6 spin types of serving repeated 6 times, which are topspin, backspin, left-side spin, right-side spin, left-side downspin and right-side downspin. Each player performed 180 receives in total. Every serve was driven by the same table tennis player at national-level, produced a neutral and offensive situation as real games. Receiving quality was determined by simultaneous record of success rate and accuracy of target area on the table. Results: National-level players significantly scored higher than senior high school players on agility, judgment, and match-like condition in terms of receiving success rate (P<0.03); however, there are no significant differences on basic control and reflection. Moreover, national-level players outperformed senior high school players on control, reflection, judgment (P<0.05), and agility (P<0.01) in receiving accuracy. The participants were also evaluated by different spin types and it is found that national level players performed better on every spin types, especially on left-side spin and left-side downspin in the aspect of both success rate and accuracy (P<0.01), which signifies that senior high school players cannot control more complicated spins as well as national level players. Conclusion: This authentic, reliable and valid study specifically indicates the differences of forehand receiving quality in national level and senior high school level players, which can be used as an efficient instrument for evaluating forehand receiving quality. By these test results, coaches can adapt and apply different training programs to improve receiving ability of individual player.

ACUTE AND CUMULATIVE EFFECTS OF DIFFERENT TIMES OF RECOVERY FROM WHOLE BODY VIBRATION EXPOSURE ON MUSCULAR POWER

Junta de Andalucía, Spain

INTRODUCTION

Vibration training has been introduced lately into training routines by using different platforms. These machines are capable of, by means of oscillatory movements, provoking a mechanical stimulus that gets transmitted throughout the whole body, stimulus known as Whole Body Vibration (WBV) (1). Through this stimulus, the gravitational load the neuromuscular system undergoes is increased. After applying different training parameters, contradictory acute and chronic effects were transversal on muscle power of lower limbs (2). To the best of our knowledge, the influence of different recovery times between exposures has not yet been assessed.

This study was based on the hypothesis that the duration of the recovery interval is affected whether the applied vibration stimulus during training is acute or chronic.

AIM

This experiment was designed to assess, the acute (Study I) and cumulative (Study II) responses of muscular power to different recovery times after WBV exposure.

METHODS

All subjects (mean age 19.7 ± 1.9) were healthy and physically active. In both studies, subjects were exposed to a WBV bout of 6 exposures of 60 seconds each, frequency 30 Hz, amplitude 4 mm; this protocol has already been tested in previous studies (3). In Study I subjects (n=30) underwent 3 trials on different days, each trial including one bout of vibration training with 1, 2 or 3 minutes’ recovery between exposures to WBV. Muscle power was measured before and after each bout. In Study II, subjects (n=45) were randomly as-
signed to 4 weeks’ WBV training (3 bouts/week) with either 1 or 2 minutes’ recovery, or to a control group. Muscle power was measured before and after each bout. In both studies, muscle power was measured using a lineal encoder with the subjects performing a half-squat exercise using a Multipower machine equipped with calibrated disks.

RESULTS
In the acute study, recovery times of 1 and 2 minutes resulted in an enhancement of muscle power (p < 0.05) while 3-minute recovery did not, the 2-minute recovery proved to be the most effective. In the long-term study, however, while both recovery periods also enhanced muscle power (p < 0.05), the 1-minute recovery proved to be more effective, since the response was modified by systematic stimulation.

CONCLUSIONS
2-minute recovery periods provided the most effective acute enhancement of muscle activation, while the 1-minute recovery provided a more effective cumulative enhancement of muscle power.

second one (decreases also higher than 30%), while in the third round we noticed great inter-individuals variations between athletes, due to each technical-tactical characteristic.

Conclusions
The experimentation state that the fatigue weigh on the kicks rapidity in TKD proportionally to the length of the match, with a progressive decrease of the rapidity during the three fighting rounds, especially in the 2nd.

This decrease weigh the match tactic adopted by each athlete.

In the preparation of the TKD results fundamental:
1) To organize the training of the elite athletes, taking care in a specific way the development of the rapidity endurance
2) Pay great attention to the tactical management of the matches.

RUNNING EXERCISE AFFECTS MAXIMAL ISOKINETIC TORQUE, BUT DOES NOT AFFECTS TOTAL WORK AND TIME TO PEAK

Denadai, B., Caputo, F., Oliveira, A.
Human Performance Laboratory, Brazil

Introduction
Running exercises are commonly used in many recreational practices and sports, in which the muscular fatigue can decrease the skills and performance. Previous studies have been conducted concerning the strength losses after running exercises at different intensities and durations, however, the relationship between the effects of an aerobic running exercise in neuromuscular variables during isokinetic tests (peak torque [PT], total work [TW] and time to achieve peak torque [TPT]) could be more explored. The main objective of the present study was to verify the effects of a continuous running exercise on the isokinetic PT, TW and TPT.

Methods
Sixteen healthy males (12±2.6 years, 180.3±6.4 cm, 80.3±12.3 kg; VO2max 46±8 ml kg⁻¹ min⁻¹) performed the following tests on different days: 1) an incremental test in a treadmill (INBRAMED Super ATL, Porto Allegre, Brazil), in order to determine maximal oxygen uptake (VO2max) (Cosmed Quark PFT ergo, Rome, Italy, and the velocity at onset of blood lactate accumulation vOBLA (YSI 2300, Ohio, USA); 2) 5 maximal isokinetic knee extensions (System 3 PRO, BIODEX Medical Systems, NY, USA), to determine the peak torque, at 180° s⁻¹ under concentric (C-180) and eccentric conditions (E-180), in random order; 3) the same isokinetic protocol described previously, performed 15 minutes after a continuous running at 95% vOBLA (9.06±1.9 km h⁻¹, 74.2±9.3% VO2max), in which the duration was estimated to a caloric expenditure around of 500 Kcal (35.07±5.93 min) for all subjects. All tests were separated by at least seven days. PT, TW and TPT were obtained by the Dynamometer software, and the comparisons between pre and post-exercise conditions were made by using a two tailed Students Paired t test.

Results
Significant differences were found for PT at E-180 between pre (325.5±60 N.m) and post exercise (306.4±69 N.m) (p<0.05) with no differences to PT at C-180 (pre = 169±4 ± 33; post = 172±9 ± 32 N.m). Significant differences were found for TW during concentric contractions between pre (154.98±27 J) and post exercise (160.78±26.7 J), without differences for TPT (pre = 223±60 ms; post = 210±39 ms). In the same way, no significant differences were found for TW and TPT during eccentric contractions between pre (TW = 276±52.6 J; TPT = 662±228 ms) and post exercise (TW = 271±64 J; TPT = 693±206 ms).

Conclusion
Running exercise performed at 95% vOBLA decreases the PT during eccentric contractions, likely due small muscle damage. However, the similar amount of torque produced (between pre and post exercise) verified by the TW, is contrasting with your increase in concentric contractions. This fact can be related to a superimposed muscle heating on the small muscle damage. Neuromuscular patterns of the knee muscle length and torque production (described by the TPT) were not influenced in this these exercises conditions.

NEW DIAGNOSTIC MEANS IN BALANCE ABILITIES

Psalman, V., Duvac, I.
Faculty of physical education and sports, Comenius University BRATISLAVA, Slovakia

Introduction
Balance boards are widely used in the objective measurement and testing of balance abilities. Its known, that tests of easier character with less feel have higher reliability then tests that are more complicated with more feel. And to these tests with more feel belong tests maintaining dynamic balance in different positions on a stabbilographic board , which shows the level of development of dynamic balance. Balance abilities belongs to a structure of coordination abilities, and is characterized as an ability to maintain the body in a stable position or to renew this position if it is disturbed by outside interference.

Objective
The aim is to analyze reliability of the testing dynamic balance abilities on different balance boards

Methods
Balance abilities were tested on 45 students of Faculty of physical education and sports, Comenius University in ages 21 - 23. Among them there were 26 males, 19 females. By using the paired correlation we calculated the correlation coefficient with intervals of reliability and testing errors. For testing the dynamic balance abilities we chose the test of balancing on different unstable boards. Reliability of test we verified method test - retest with time interval one week. Test and retest were accomplished in a standard laboratory conditions. The goal of the tested person was to balance him/herself in the longest balance standing position on the board. The attempt was finished at the time if any part of the board touches the ground. Everybody was tested three times. We tested in the same place, at the same time of the day, on the same surface, with the same motivation and the same researchers.

Results
Relatively highly significant relationships was confirmed in the tests of dynamic balance. Test on Balance master r (corr.) = 0.78, Extrem balance boards r (corr.) = 0.75, Energetics board r (corr.) = 0.73. Test of balancing on an unstable boards r (corr.) = 0.72.

Conclusion
Tests of balancing on an unstable boards are good means for diagnostics of dynamic balance abilities in sport professions.

INFLUENCE OF PHYSICAL FITNESS ON FREESTYLE PERFORMANCE IN YOUNG SWIMMERS

Platzer, H.P., Raschner, C., Patterson, C.
University of Innsbruck, Austria

INTRODUCTION
Physical fitness requirements for swimming are diverse. According to Tanaka et al. (1993) dry-land resistance training is an important part of modern swim training. Testing of physical abilities is important to assess the athlete's general fitness and for training prescription. The aim of this study was to determine the influence of physical fitness on different events in freestyle swimming.

METHODS
34 competitive swimmers (16 men, 18 women) took part in this study. The subjects mean values ± SD for age, height and body mass were 16.0 ± 2.4 years, 170.9 ± 10.1 cm and 61.3 ± 10.7 kg. The following parameters were tested to assess the swimmers’ general fitness: isometric abdominal and back strength, isometric bench press and bench pull strength, isometric leg strength, counter movement jump (cmj), tapping and maximum velocity on a custom built swim bench (Platzer et al. 2004). All tests met scientific criteria. For statistical analysis Pearson correlation was used to test relationships between the different parameters. A multiple regression (stepwise forward) analysis was carried out to estimate swimming performance by the different parameters.

RESULTS
Isometric abdominal strength, cmj and tappings correlated significantly with 50, 100 and 400 meter, isometric back and bench press strength only with 400 meter and the swim bench test with 50 and 100 meter freestyle time in men. In women only abdominal strength (not over 50 meter) and maximum swim bench velocity correlated significantly with swim time over 50 and 100 meter. Multiple regression revealed R²=0.8, R²=0.77, R²=0.6 for men’s 50, 100 and 400 meter freestyle time respectively. In women’s 50 and 100 meter freestyle events, R² values of 0.5 and 0.63 respectively were found.

DISCUSSION
The results indicate that the test battery is a good predictor for men’s freestyle 50 meter sprint performance. For longer distances and for females the predictive value of the test battery continuously decreases. In 400 meter events other factors such as technique, endurance or anthropometric issues are more important. Interestingly, women’s strength parameters are not performance determining in this study. Perhaps kinaesthetic sense or body composition are central elements in women’s swimming performance. Maximum velocity in the swim bench tests is the most important predictor for men and women in all events except 400 meters. This indicates that sport specific strength and power testing is crucial for performance diagnostics in swimming.

FORECASTING OLYMPIC RESULTS IN AN ATHLETIC EVENT
Bruno, P.
Faculty of Human Kinetics, Technical University of Lisbon, Portugal

The Olympic Games will be hold once again next summer. The Olympic motto of ‘faster, higher, stronger’ is an aspiration of all athletes. In that sense, a question of interest is ‘how far are athletes willing to go?’

This work focusses on the triple jump. This field event was included in the modern Olympic Games since its first celebration in 1896. The Olympic record is 18.09 metres, performed by Kenny Harrison, in 1996. The distance of 18.29 metres remains as World record, although it was recorded in 1995.

This paper aims to forecast the result to be obtained by man’s gold medalist in the 2008’s Olympic. The time series with the best distance reached on each Olympic since 1986 was used in order to evaluate the forecast. The behaviour of this time series is typically autoregressive. Some of the events that occurred in the past, such as the two world wars, may have some influence in the forecast, as after the wars the scores dropped down. The high altitude of Mexico City, where the Games took place in 1968, was credited to have contributed to many records setting. We may thus think that the conditions observed after the wars, as well as the conditions found at high altitude are critical interventions to the subject we are dealing with.

Several intervention autoregressive models were estimated and some criteria were discussed in order to choose the ‘best’ model. An autoregressive model of order one with two interventions, due to the world wars, was chosen on the basis of minimum Akaike Information Criterion (AIC). The mean squared error (MSE) evaluated using errors of the one-step ahead in-sample forecast from year 1920 through 2004, and the MSE calculated using errors of the one-step ahead out-of-sample forecast between years 1980 and 2004 are also favourable to the referred model.

According to the chosen model, the point forecast to the score of triple jump 2008’s Olympic champion will be 17.76 metres, with the limits of the 95% prediction interval to be 17.06 and 18.45 metres. This prediction meets the best 2007’s performance, which was 17.90 metres, and the World Leading 2008, which is 17.42 metres.

DIFFICULTY SCORE FOR RHYTHMIC GYMNASTICS GROUP EXERCISES IN PORTIMÃO 2007 WORLD CUP SERIES
Avila-Carvalho, L., Corte-Real, A., Araújo, C., Botelho, M., Lacerda, T., Lebre, E.
University of Porto - Faculty of Sports, Portugal

The performance in rhythmic gymnastics is evaluated in competition by a final score that includes 3 sub-scores: Difficulty, Artistic and execution scores. The difficulty score represents the body difficulty level that the gymnast or the group can achieve. The aim of this study is to try to see if there is a profile in the type of difficulty elements chosen by different groups all over the world to make their choreography for competition routines.

For this study, 38 different routines from 19 different countries from 4 different continents that competed at Portimão 2007 World Cup Series were observed. The groups performed two different routines, one with 5 ropes and other with 3 hoops and 4 clubs. The analysis of the difficulty elements of the routines was made using the competitions forms that group have to give in advance to the competition organisation. We preferred to study the competition forms instead of the films because in this way the analysis will not be affected by the fails and mistakes made by the group during the competition. The classification used to organize different elements was the official
classification used in the FIG (Gymnastics International Federation) Code of Points (FIG, 2007). We so classified the difficulty body movements in five main categories: Jumps/Leaps, Flexibility/Waves, Balances, Pivots and Exchanges. Analysing the main results we could conclude that in the Jumps, for all groups and for the 2 different routines they preferred performed difficulties with different kinds of "jeté en tournant". For group of Balance elements the most performed element was the balance with the trunk at the horizontal with different position of the other leg., also for the two different types of routines. For the pivots the most used were the pivots with the leg high (in front or side) For the flexibilities/waves we could mark that were the splits with the on the horizontal positions the preferred elements for the sample observed. To compose the difficulty elements the groups observed have chosen for both routines preferably Jumps and Flexibility/Waves.

Analysing the Exchange elements the results showed that the majority of the Exchange elements have no body difficulty elements included. But when it happens the groups have chosen the jumps in both type of routine.

CARDIAC LOAD IN TEAMGYM PERFORMANCE

De Pero, R., De Ioannon, G., Minganti, C., Capranica, L., Piacentini, M.

Universitàl Institute of movement sciences, Italy

Introduction

Teamgym is a fairly new and popular form of Gymnastics including only trampoline, tumbling and floor exercises. While artistic gymnastics has been closely studied during simulated competitive routines with respect to cardiovascular load, power, endurance, heart rate, blood lactate concentration, and VO2max [Noble, 1975; Jemni et al., 2002, Goswami, Gupta, 1998], teamgym has never been investigated. The aim of the present study was to investigate the cardiac load in teamgym performance during National and European Championships.

Methods

Ten Italian elite gymnasts, 5 males and 5 females, (mean age 21 ± 2) performed the same exercise program during National (NC) and European Teamgym Championships (EC). Gymnasts’ cardiac load (HR) was measured recording heart rate (Polar team System) in each competition, during the three routines. For the analysis of the physical load, heart rate was classified based on the percentage of time spent in three zones (Low-intensity: <85% HRmax; High-intensity: 86-95% HRmax; Maximal effort >95% HRmax). Statistical comparison among heart rate values in each of the three routines in different championships were made using non parametric Friedman's Test ANOVA.

Results

Differences (p<0.05) in heart rate emerged between NC and EC only in the tumbling routine with higher values during EC (86-95% HRmax = 29%) than NC (86-95% HRmax = 9%). Furthermore differences were found for apparatus in each competition (p<0.05). During Tumbling subjects remained at the lower intensity frequencies (<85% HRmax) for the majority of exercise time (NC= 91%, EC= 71%). During trampoline routines the more frequent zones were low-intensity (<85% HRmax: NC= 70%, EC= 53%) and High-intensity ones (86-95% HRmax: NC= 30%, EC= 47%). The highest cardiac load was observed during the floor exercise (<85% HRmax: NC= 53%; EC= 46%; 86-95% HRmax: NC= 46%; EC= 45%). Furthermore 1% and 9% of frequency of occurrence of HR > 95% HRmax were observed during NC and EC respectively.

Discussion/Conclusion

As expected, Teamgym competitions elicited a very high cardiac load, with differences between apparatus. Actually, during the trampoline and tumbling gymnastics perform rounds of acrobatic elements between rest periods, while the floor exercises require fluid routines with no rest periods, which elicit higher HR. Despite the exercise program did not differ between National and European Championship, the higher HR observed during the latter competition might be attributed to a higher arousal determined by the higher level and importance of the event.

WHICH IS THE MOST VALID INDEX OF EXPLOSIVE STRENGTH DURING AN ISOMETRIC LEG PRESS TEST?

Galvani, C., Colombo, A., Martora, S.

1Motor Science, 2School of Sport, Italy

Explosive strength is the ability to exert maximal forces in minimal time and is important for success in several sports. A popular method for measuring explosive strength is isometric testing, and various force/time indexes have been proposed in the literature [1, 2]. The aim of the present study was to determine the validity of these indexes of explosive strength during an isometric leg press test, by exploring their correlation with vertical jump performance (VJP).

Explosive strength of 14 healthy and active male subjects (age 25±2 years, height 178±7 cm, weight 84±12 kg) was tested with an isometric dynamometer mounted on a horizontal leg press with a 120 degree knee angle [3]. VJP was measured as height reached during a countermovement jump. Statistical significance was set at 0.05.

Only rate of force development (r = 0.66, p<0.01) and starting gradient (r = 0.57, p<0.05) were significantly correlated with VJP. None of the other indexes of explosive strength were significantly correlated with VJP. Some of the rates with the leg high in front were significantly correlated with VJP time to 500N r = 0.18, time to 30%MVC r = -0.14, time to 50%MVC r = -0.36, time to 90%MVC r = -0.28, force at 30ms r = 0.07, force at 100ms r = 0.35, explosive strength index r = 0.14, reactivity coefficient 0.13, acceleration gradient r = 0.11).

These results demonstrate that the choice of which explosive strength index to use during isometric tests can not be arbitrary. When the aim of the isometric test of maximal strength is to infer dynamic performance, we suggest the use of rate of force development and starting gradient. All the other indexes of explosive strength should not be used for athletic assessment.

ARTISTIC VALUE SCORE FOR RHYTHMIC GYMNASTICS GROUP EXERCISES IN PORTIMÃO 2007 WORLD CUP SERIES

Avila-Carvalho, L., Corte-Real, A., Araújo, C., Botelho, M., Lacerda, T., Lebre, E.
University of Porto - Faculty of Sports, Portugal

The performance in rhythmic gymnastics is evaluated in competition by a final score that includes 3 sub-scores: Difficulty, Artistic and execution scores. The main liability of the final score depends on the artistic score (Lebre, 2007). In the Code of points last modifications we could find some improvements that transformed this part of the final score more precisely. The aim of this study is to see if there is a profile in the type of artistic elements chosen by different groups all over the world to make their choreography for competition routines. For this study, 38 different routines from 19 different countries from 4 different continents that competed at Portimão 2007 World Cup Series were observed. The groups performed two different routines, one with 5 ropes and other with 3 hoops and 4 clubs. The analysis of the artistic elements of the routines was made using the competitions forms that group have to give in advance to the competition organisation. We preferred to study the competition forms instead of the films because in this way the analysis will not be affected by the tails and mistakes made by the group during the competition. The classification used to organize different elements was the official classification used in the FIG (Gymnastics International Federation) Code of Points (FIG, 2007). So we divided the artistic elements in 3 main categories: Mastery (MAST), CAP's (Particular Artistic Characteristics) and Collaborations among gymnasts (COL).

Analysing the main results we could concluded that for MAST the groups preferred the bonification using throws for both type of apparatus but when we compare the routines with different type of apparatus we could observed that the bonus for catches were considerably higher in hoop/clubs exercise. For COL we concluded that in rope routines they use more the COL with simple throw and the RRT COL, but in the hoop/clubs exercise they preferred the COL with simple throw. For CAP's we could conclude that for rope the groups preferred to use the jumps through de rope and for the hoop/clubs route they preferred the handling of the apparatus.

In general we could design a profile for each kind of apparatus, but this profile is not the same for the two routines of the same group.

DESIGNING, VALIDITY, RELIABILITY AND NORM PROVIDING OF TAEKWONDO SKILL TESTS

Kashef, M., Ramezani, A., Alizade, M.
Shahid Rajaee University, Iran

Taekwondo is one of the martial arts and in recently years joined to Olympic Games. But it has no any skill test. The purpose of this research is designing, validity, reliability and norm providing of Taekwondo skill tests. For designing of Taekwondo skill tests, first, discussing by the coaches and elite athletes and then, designing five tests for measuring the Taekwondo skills. 10 young men ages 20 ± 2 years of Karaj Piroozy Taekwondo Club were selected voluntarily and participated in testing for determining of validity and reliability. Statistical analyses were Spearman Correlation Coefficient and Cronbach Alpha.

The results showed three tests of five tests have a suitable validity and reliability. There were significance relationship for Foot Speed Bit (r= 0.65, a= 0.75), Hand Power Bit (r= 0.61, a= 0.81) and Speed Combination Skills (Eleven Bits) (r= 0.58, a= 0.79) (p<0.05).

Finally, based on the records were made norm for three skill tests and suggestion the Taekwondo coaches can measurement the skills of Taekwondo by these tests.

MATCH ANALYSIS IN FEMALE FUTSAL

Benvenuti, C., Tessitore, A., Capranica, L.
University Institute of Movement Sciences, Italy

Introduction

Although match analysis has been largely used to evaluate the demands of competition of team sports (Bangsboo et al., 1991; Pers et al. 2002), the few studies on futsal (Barbero-Alvarez et al., 2008; Soares and Tourinho Filho, 2006; Tessitore et al., 2007) involved only male players and were mainly focused on time motion analysis. Therefore, the aim of the present study was to analyze the tactical profile of female futsal matches.

Methods

Fifteen official matches of the Serie A 2006-2007 Italian Women’s Futsal Championship were analyzed. Each match was recorded by means of two cameras positioned at the side of the pitch. The videotapes were later replayed to analyse three tactical situations to score a goal: 1) Counter-attack (CA), i.e., 1vs0, 1vs1, 2vs1, 2vs2; 2) Set-Pieces (SP), i.e., Free-kick, Corner-kick, Penalty-kick, Kick-in, 10m Second-penalty, Goal-kick; 3) Passing Attack (PA) against a defensive alignment of the opponent team, i.e., an offence based on passes, screens and cuts designed to prepare for favourable shooting position. A chi-square test was applied to verify differences (p<0.05) between halves. The goals were expressed as percentages of the total.

Results

During the 15 matches 80 goals were scored. Higher percentages of goals were scored during SP (36%) and PA (35%) with respect to CA situation (29%). Despite CA and PA determined higher percentages of goals in the first half (64% and 61%, respectively) and the reverse picture emerged for SP (first half: 41%, second half: 59%), no difference was observed between halves. During CA, goals were more frequently scored from 2vs1 (43%) and 1vs1 actions (35%), than 1vs0 (13%) and 2vs2 (9%). During SP, goals resulted more frequently from Kick-in (31%), Corner-kick (31%), and Free-Kick (21%) than from 10m Second Penalty and Goal-kick (7%).

Conclusions

In team games the detailed analysis of the most relevant tactical situations to score goals is helpful to elaborate appropriate training strategies. The present results suggest that training Counter-Attack, Set-Pieces, and Passing Attack is equally relevant in female futsal. In particular, 2vs1, 1vs1, Kick-in and Corner-kick resulted the most important situations to train. The lower percentages of goals scored as a
result of Counter attack and Passing Attack during the second half might be probably due to fatigue occurring towards the end of the matches.

INTENSIFICATION OF A TRAINING PROCESS OF GYMNASTS AT THE SPORT SPECIALIZATION STAGE

Shlyathtov, V., Semenov, D., Medvedeva, E.
Velikiye Luki Academy of Physical Education and Sports, Russia

Constant growth of achievements in gymnastics makes it necessary to study the process of training of gymnasts in details and find new ways to improve it. The stage of sport specialization is a significant phase of the athletes’ mastery. Its further development, in many respects, will depend on effectiveness of the stage.

The training process at the sport specialization stage is supposed to be more productive if the selection of means and methods of the gymnasts’ training is based on the analysed results of kinematic parameters and peculiarities of the muscle bioelectric activity, registered during performance of gymnastic exercises.

25 gymnasts, aged 10-12 took part in the investigation. The sportsmen were mastering the main exercises of the specialization training stage in combined events (handspring and back flip in acrobatics, giant circles on a horizontal bar, handspring vault, etc.).

The quality of the main exercises performance was assessed by comparison of the characteristics, registered in the process of biomechanical researches, of the gymnasts participating in the investigation and those of high qualification.

To reveal the extent and sequence of various muscle groups, performing the main exercises, to join in the work, a method of surface electromyography was used.

The process of the tests a support programme of physical fitness training was worked out. The gymnasts’ level of the physical fitness after the investigation increased in average by over 30%.

The muscle groups performing the studied movements made the core of the means of the support programme.

Comparison of the data received during the biomechanical and electro-myographical researches allowed to define the mechanisms of the performance of the main exercises of the sport specialization stage and succession of complicated moving skills formation on the base of the programme of handstand, spin and take/push-off training.

The number of successful attempts of handstand exercises (4 tests) increased after the test in average by 2.8 times; the increase of push-off exercises (2 tests) made 2.45 times, a take-off exercise (1 test) made 1 time increase.

Good basic skills (handstand, dynamic posture and push-off) made the most contribution into the quality of the performance of the main exercises mastered during the investigation. The score for the performance of the main exercises increased in average by over 0.9 points.

The results of the investigation showed that the programme of the combined events main exercises mastering, including sub-programmes of the basic and support physical training of the gymnasts, is pedagogically expedient in training gymnasts at the sport specialization stage.

WRESTLING COACHES AND EDUCATIONAL NEEDS

Martins, P., Rosado, A., Mesquita, I.
Faculdade de Motricidade Humana, Portugal

Background

Despite an increasing recognition of the existence of a process of coaching, and a resulting increase in research activity, there remains a lack of a clear conceptual base for sports coaching (Cushiona, Armourb, & Jones, 2006). In wrestling it is not sufficiently answered what are the specific and essential things that coaches need to know in order to achieve competitive results! This situation has left coaching without a clear set of concepts and principles that reflect coaching practice on wrestling. In this paper, using a qualitative approach we will consider the expert coaches knowledge foundation to further describe what they consider the most important professional knowledge.

Method

The study involved in depth interviews to 6 expert coaches. At the time of the interview all of the coaches were training a team. The ages of the participants ranged from 31 and 53 years. Three of the 6 coaches were Portuguese, two were Spanish and one was Cuban working in Portugal. The interview questions concerning educational needs were part of a larger interview addressing pedagogical content knowledge in wrestling.

The 6 interviews were conducted in a direct, in-depth interview format in a time and location in order to ensured confidentiality and noninterference from others. After participants agreements the interviews were tape-recorded and then transcribed. The procedure used to look at the answers was the content-analysis, consisting on repeatedly transcriptions reading and listening to the interviews tapes. After that, we look for emerging themes, assigning compiled or paraphrased quotations using inductive and deductive procedures for further categorization.

Results and Conclusions

Coaching Education Background Profile

Educational levels of the participants varied. All the coaches had completed a federation course, which makes them possible to coaches. They considered experience as an athlete of there own the most important sources to develop their coaching style and knowledge, followed to academic graduation in sports sciences, except one of them which is graduated in industrial engineering.

Reading coaching books and journals, navigate in the web, “going out” and contact with others is considered as well the most important sources of professional knowledge for coaching.

Future Coaching Education Needs

Considering ultimately others needs, the coaches shows concerns about getting awareness of sports medicine, biomechanics, psychology, physiology and marketing. They state that the new wave of coaches must be integrated in a vast team of experts in each area.
indicated to prepare young coaches for elite level coach is needed. Thus mentoring programs the young coaches should learn to develop
their own style and knowledge from working with top coaches at the same time they work in a national level. With that, they will learn the
environment of competition so well considered to achieve higher results.

INFLUENCE OF THE EXERCISE CONSTRAINTS IN THE SOCCER TRAINING
Leitão, J., Almeida, J., Martins, N.
UTAD, Vila Real, CIDESD, Portugal
The aims of the study were to investigate the intensity of soccer training exercises and to analyse the variation of distance and speed
according to the restrictions of the exercises (Adjustment circle, Bangsbo, 1994). The sample was formed by soccer juniors A players (N= 10) that participated in the Second Division of the National Championship. The images of the exercises were gathered in video (miniDV format) and subsequently digitalised. They were analysed by TMAS software that estimated the distance and speed of the players.
Non-parametric tests were used (Mann-Whitney, Kruskal-Wallis, Wilcoxon, Friedman) to compare and correlate the study variables. The comparison of the distance and speed in 6 against 6 (6 x 6) and 4 against 4 (4x4) exercises showed significant (p<0,05) differences. It was found that the distance and speed results were always higher in 6x6 than 4x4 exercises. However, when the limit of kicks and goals
were employed, the results revealed that only the limit of kicks influenced significantly distance and speed. The results also support the
conclusion that the intensity of the effort increased in a proportional way with the number of players and playing area.

THE EFFECT OF INSPIRATORY MUSCLE TRAINING UPON CARDIORESPIRATORY PRIMARY KINETICS RESPONSE IN
ENDURANCE ATHLETES
Tomiai, T., Mishchenko, V.
Academy of Physical Education and Sport, Poland
It’s known that Inspiratory muscle training (IMT) may increase respiratory muscle power-endurance, working capacities, respiratory re-
sponse to CO2, perceptual response and lactate kinetics (1,2). Whether or not these benefits and athletes’ working capacities can be
achieved by only increasing of respiratory muscle possibilities remains open for debate. It was hypothesized that effects of IMT may be
linked with increase of respiratory primary kinetics. The purpose was to determine the effects of IMT on respiratory, gas exchange fast
kinetics and exercise performance.
Twenty two of male high performance runners (Vo2 max = 70,4-73,6 ml kg-1 min-1) were randomized into two groups and perform the
same program of preseason training for three weeks (18 sessions). 10 athletes were assigned to IMT group and 12 athletes were received
sham inspiratory training with the same device (control group). IMT group performed ten repetitions (interval 2 min) of 30 inhalation-
exhalation (Powerlung) two times a day for three weeks with resistance adjusted to allow for 30 breathes to be close about 3 of maximal
effort. Before and after IMT athletes primary kinetics (T50, monoexponential, breath by breath method, transition from 100 w of VO2,
VCO2, VE and HR in rowing ergometer exercise at 0,75 VO2 max and performed 2000m all-out rowing simulation.
The results showed that IMT produce significant increase in VE peak response in comparison with control group (2,12±0,17 and 1,89±0,15
l.min-1.kg-1; p<0,05) and in primary kinetics. In IMT group T50 VE decreased from 39,12(7) to 31,9(2,8) s (p<0,05), in control group - from
38,3(2,9) to 36,4 (2,7) s (ns), T50VCO2 : in IMT group from 36,9 (2,4) to 33,7 (2,7) s (p<0,05); in control group - from 38,2 (2,6) to 36,0 (2,7) s
(ns) and V50 HR - in IMT group from 21,2 (1,2) to 17,6 (1,2) s (p<0,01), in control group - from 20,8 (1,4) to 19,2 (1,3) s (ns). The changes of
and VE peak (r=0,65) for all-out rowing simulation (r=0,61). In IMT group increased some measurements of working capacities also.
It may be related to increase VO2 utilization, power of metabolic acidosis respiratory compensation and respiratory drive mecha-
ism.

CARDIORESPIRATORY REACTIVITY MODIFICATION RELATED TO SPORTS SPECIFIC ENDURANCE TRAINING
Mishchenko, V., Lysenko, E.
Academy of Physical Education and Sport, Poland
The sports specific capacities of cardiorespiratory system (CRS) usually related to specific metabolism for different power of loads. We
suppose that repetition of uniform character of endurance sports training provides an increase in specific optimization of CRS respon-
siveness also. The aim of the studies was to determine the differences in CRS responses to CO2 and in CRS, gas exchange fast kinetics in
middle and long distance runners.
Two groups (20-24yrs, 5-8 yrs training) of middle (800 m, n=15; body mass 75,1±1,2 kg) and long (5000 m, n=16; 70,6±0.9 kg) distance
runner were examined. The treadmill incremental to exhaustion (10-14 min), at 53,5(49,1-56,3)% VO2 max (5min) and at power VO2 max
(5min) exercises were used. Peak responses and fast kinetics (half-period - T50, monoexponential, breath by breath method, transition
from 6 km hour-1) were determined. Capillary blood lactate was measured after incremental load. Rebreathing VE sensitivity to CO2 was
determined.
The results showed that in incremental treadmill load to exhaustion the peak of lung ventilation (VE) was higher in long distance as com-
pared to middle distance runners (2,22±0,10 and 1,87±0,11 l.min-1.kg-1; p<0,05). Blood lactate after load was higher in middle distance as
compared to long distance runners (11,9±0,76 and 8,10±0,91 nmol.l-1, respectively). Besides, middle distance runners have been also
characterized by lower value of VE/ VCO2 than long distance runner (32,7±1,36 and 36,6±2,23) and by higher peak value of
VCO2/VO2 during recovery period (1,23±0,11 and 1,04±0,08, respectively; p< 0,05). The peaks of gas exchange ratio (VCO2/VO2) after
incremental load was related to VE sensitivity to CO2 \( r = 0,59; p < 0,05 \).
Fast kinetics VO2, VE at submaximal load were higher in in middle distance runners as compared to long distance runners. For instance,
T50 VO2 has constituted 25,3±1,7 and 28,9±2,1s, where as T50 VE - 38,5±2,8 and 45,9±3,3 s, respectively; p<0,05). But at power of VO2
max - the fast kinetics was the lower in the group of middle (T50 VO2 22.8±2.4s) than in long distance runners (25.4±2.7 s). Sensitivity of CRS responses to CO2 (VE/PACO2) was higher in middle distance (1.59±0.11) than in long distance runners (1.09±0.14 l/min-1 mm Hg-1 l). In middle distance runners individual differences in T50 VE and VCO2 have been related to VE sensitivity to CO2 (r=-0.67 and -0.65, respectively, p<0.05). The lung ventilation at PACO2 = 50 mm Hg was reliable higher in middle (29.5±2.0l/min-1) than in long (20.7±2.8 l/min-1; p<0.05) distance runners.

The results showed differences in sensitivity to CO2 in middle and long distance runners and in fast kinetics of CRS response as well as VO2 and VCO2 kinetics. The higher values of sensitivity to CO2 and fast kinetics at power of VO2 max in middle distance runners were related to higher intensity of metabolic acidosis respiratory compensation in comparison with long distance runners.

**TRAINING LOAD IN AN IRONMAN PREPARATION MACROCYCLE**

Ensenyat, A., Blanco, A.

National Institute for Physical Education and Sports of Catalonia, Spain

**INTRODUCTION**

Ironman is one of the official triathlon competition, that includes 3,8 km swimming followed by 180 km road cycling, and that ends with a marathon running (42.195 km). Due to the prevailing aerobic demands, from a physiological point of view, Ironman is considered an ultraendurance effort.

During the Ironman training process, it is essential to determine and evaluate the training load in order to quantify the magnitude of the effort done, and to control the degree of fatigue of the triathlete. Quantification of the load, by means of heart rate, can be done easily using the total number of beats, or total heart rate, of each session and/or microcycle.

**PURPOSE**

The aim of this study was twofold; (a) to determine the training load in a macrocycle of 24 weeks for the preparation of an Ironman and (b) to relate the training load with the volume (time and distance), and with the intensity (mean speed and mean heart rate) of the training.

**MATERIAL AND METHODS**

An amateur triathlete (32 years, 1.76 m of height, 71 kg of weight), with six years of training experience and a best performance of 10 h 58 min.

Heart rate was registered in each training session using a heart rate monitor “Polar XTrainer-plus”. Distance covered and time expended in each training session were also measured. In running and cycling sessions, distance was measured using a GPS “Garmin Forerunner 201” and the heart rate monitor.

**RESULTS**

The triathlete did 196 training sessions. He devoted 336.11 hours to cover 5996.89 km. He swam 209.22 km, and did 4856.7 km cycling and 930.96 km running.

Half of the training sessions represented a small training load (< 9000 total number of beats), and only 16% of the training sessions supposed an extremely high level of training load (> 22500 beats). The mean training load was of 117.952 (DE 61.407) total number of beats, ranking from 18453 to 233438 beats.

The total number of beats of each microcycle correlates significantly with distance (r=0.97), time (r=0.99) and the mean speed (r=0.66).

On the other hand, total number of beats did not correlate with mean heart rate. Training volume (distance and time) correlated with mean speed (r=0.76 and 0.66), but mean heart rate did not correlate with any variable.

**CONCLUSIONS**

Training load, measured as total number of beats, is more sensitive to the training volume of microcycles than to the physiological intensity (mean heart rate). It allows to assess the effort done and to control the dynamics of the training process of the triathlete.

**EFFECTS OF SMALL-SIDED GAMES ON PHYSICAL CONDITIONING AND PERFORMANCE IN PUBERTAL SOCCER PLAYERS**

Katis, A., Kellis, E.

ARISTOTLE UNIVERSITY OF THESSALONIKI, Greece

**INTRODUCTION**

Small-sided games are extensively used by coaches for improving technical and tactical skills among young soccer players (1).

**PURPOSE**

To examine the fatigue effects induced by small-sided games on soccer physical conditioning and field test performance in pubertal soccer players.

**METHODS**

Fourteen pubertal soccer players (age: 14 ± 0.98 yrs, body mass: 62 ± 17.65 Kg, height: 168 ± 7.97 cm) participated in the study.

Small-sided games included games 3 vs 3 and 6 vs 6 in standard pitch size, with adopted rules and coach encouragement (2).

Each small-sided game consisted of 10 bouts of 4 min duration with 3 min active recovery between bouts. The recovery between the 5th and the 6th bout was 15 min. Soccer performance was evaluated via the implementation of five field tests: a) 30m sprint, b) throw-in for distance, c) agility test (Illinois Agility Test), d) dribbling the ball and e) horizontal jump. Heart rate was monitored during the entire testing session and it was used for the estimation of game intensity. Field tests were performed before (pre), in the middle and after (post) the implementation of the fatigue protocol.

**RESULTS**

Three-a-side games displayed higher heart rate values compared with 6 vs 6 games (86.9 ± 4.77% of HRmax versus 75.9 ± 6.22% of HRmax, respectively). Performance indices significantly decreased (P<0.05) in the middle and after the implementation of 3 vs 3 games (30m sprint: pre= 5.04 ± 0.32sec, middle= 5.21 ± 0.33sec and post= 5.34 ± 0.35sec. Agility test: pre=17.07 ± 1.02sec, middle= 17.60 ± 1.19sec and post= 18.01 ± 1.34sec. Dribbling: pre= 11.4 ± 0.48sec, middle= 11.99 ± 0.75sec and post= 12.85 ± 1.53sec. Horizontal jump: pre= 2.02 ± 0.15m, middle= 2.00 ± 0.17m and post= 1.87 ± 0.13m. Throw-in: pre= 14.81 ± 1.02sec, middle= 13.60 ± 3.04m and post= 12.45 ± 2.81m). During 6 vs 6 game situation, only 30m sprint and agility test were significantly lower (P<0.05).

**DISCUSSION**

The results of the present study indicated that small-sided games with 3 players led to increased intensity and therefore increased fatigue towards the end of the game, which has negative effects on player's performance. However, when the number of players increased, heart rate intensity decreased, while fatigue did not have the same effect on technical skills (dribbling) and explosive actions (horizontal jump and throwing) but only on agility and sprinting performance. Previous studies have reported that alterations in performance are accompanied by significant decline in muscle strength capacity and activation levels (3,4), which probably explains the decline in performance observed in the present study. However, small-sided games are strongly recommended for young ages due to higher involvement of players in the game.

NEUROMUSCULAR AND FORCE PROFILE OF THE SWALLOW AT THE GYMNASTIC STILL RINGS AND RECOMMENDATIONS FOR TRAINING EXERCISES

Bubeck, D., Arnold, R., Alt, W.
University of Stuttgart, Germany

The swallow at the rings can be rated as extreme challenging and strong determined element, which is only shown from excellent gymnasts. Due to the high quality rating of the swallow within the Code de Pointage of the Fédération Internationale de Gymnastique (FIG), this difficult technical element must be shown in a gymnastics exercise. The problem thereby is, that the training of the swallow takes a huge amount of time. So the following question arises: Is it worth spending time on developing the swallow or should this time better be used to train other elements? In order to help trainers and athletes answering this question, the purpose of this study was to develop a huge amount of time. So the following question arises: Is it worth spending time on developing the swallow or should this time better be used to train other elements? In order to help trainers and athletes answering this question, the purpose of this study was to develop

Six expert gymnasts who were able to perform the swallow took part in the study. They performed the original version of the swallow and six special trainer-assisted exercises for the swallow. Within the cables of the rings force transducers detect the tensile force. Surface EMG was depicted of ten muscles according to the recommendations from Sands (2006).

Considering the neuromuscular activation levels from the different muscles contributing to realize the swallow, high individual differences can be observed. These differences could be based on varying anatomical and anthropometrical prerequisites. Regardless these individual differences the mm. pectoralis clavicularis, biceps brachii, deltoideus anterior, trapezius and pectoralis sternocostalis were proved to be the most important muscles.

The aptitude of the tested training exercises to develop the special skills for performing the swallow was therefore not possible solely based on the electromyographical data. Regarding the force data it could be assumed that the force output was enhanced if the support from the coach was given more caudal. Based on these data a ranking of the different training exercises was fixed.

In order to simulate different anatomical and positional differences of the athletes performing the swallow a mechanical model was designed. With this model it can be shown, that the angle between the arms and the body play an important role in terms of a successful performed swallow.

It could be concluded that these results were able to support the training process for the development of the swallow in order to provide different ranked training exercises. The muscle profile helps the coaches to find training exercises which are able to enhance muscular force without using the special training exercise. So the long term periodization becomes more efficient.

MEASURED MAXIMAL OXYGEN UPTAKE DURING AN INCREMENTAL VELOCITY CONTROLLED FIELD AND TREADMILL RUNNING TEST

Willems, M., Fordham, R.
University of Chichester, United Kingdom

BACKGROUND: Maximal oxygen uptake is an indicator for aerobic endurance capacity. The multistage 20 m shuttle run test with 1 min stages is a popular field test to predict maximal oxygen uptake (Tomkinson et al. 2000). In this test, subjects run back and forth between 2 parallel lines, marked 20 m apart, in time to sounds. Predicted maximal oxygen uptake by the 20 m shuttle run test in a Figure of 8 (20MST-Fo8) was shown to exceed the value predicted from the line to line 20 m shuttle run test (Willems & Garatt, 2007). However, measured maximal oxygen uptake for the 20MST-Fo8 is not known. PURPOSE: We examined maximal oxygen uptake for the 20MST-Fo8 and a treadmill running test (MST-TRT, 0% gradient) with similar increases in velocity (0.14 m/s each minute) in both tests. METHODS: A random crossover design was used with the 20MST-Fo8 run indoors. Subjects ran the 20MST-Fo8 and MST-TRT until volitional exhaustion. Peak velocity, total running time, maximal heart rate, ratings of perceived exertion (RPE), blood lactate and maximal oxygen uptake using a Cosmed K4b2 portable gas analysis system were measured in 9 healthy, physically active, males (20.2 ± 0.4 yr, body mass 75.1 ± 9.9 kg, height 1.78 ± 0.06 m, mean ± SD). Data were analysed with a paired samples Student t-test with P<0.05. RESULTS: The 20MST-Fo8 and MST-TRT resulted in similar ratings of perceived exertion (19.6 ± 0.7 vs 19.2 ± 0.7). The 20MST-Fo8 had lower peak velocity (13.4 ± 0.68 vs 16.39 ± 1.08 km/h, P<0.001), shorter total running times (640.8 ± 81.8 vs 987.3 ± 145.6 seconds, P<0.001), lower maximal heart rates (192 ± 8 vs 195 ± 7 beats/min, P=0.022) and lower blood lactate values (7.5 ± 1.2 vs 8.2 ± 1.2 mmol/L, n=7 each, P=0.021) compared to the MST-TRT. However, measured values for maximal oxygen uptake were 15% higher for 20MST-Fo8 (62.4 ± 5.9 ml/(kg/min) compared to MST-TRT (54.5 ± 5.0 ml/(kg/min)) (P=0.001). CONCLUSIONS: Maximal oxygen uptake by the 20 m shuttle run test in a Figure of 8 is larger than measured for an incremental treadmill running test with similar changes in speed as in the 20 m shuttle run test. The nature of the running movement during a 20 m shuttle test in a Figure of 8 limits may involve a larger active muscle mass compared to treadmill running. However, it cannot be excluded that the longer total running time for the treadmill test compared to the 20 m shuttle run test in a Figure of 8 may have contributed to the lower maximal oxygen uptake values.

DIFFERENCES IN PHYSICAL CAPACITIES BETWEEN SPANISH JUNIOR MALE BASKETBALL PLAYERS ACCORDING TO THEIR FINAL LEVEL OF ADULT PERFORMANCE (ELITE VS. NON-ELITE)

Olmedillas, H., Calleja-González, J., Mijaanes, J., Terrados, N.

Laboratory of Physiology and Human Performance. Faculty of Physical Activity and Sport Sciences. University of Las Palmas de Gran Canaria, Spain

Determining player selection criteria is one of the important current topics in competitive team sports such as basketball. In recent years, physical capacities have been assuming a more important role as parameters for player selection. Coaches often assume that more elite players will perform better on physical conditioning tests and therefore they are more likely to select these players for their team. Scant scientific literature exists, however, regarding the validity of the specific parameters used to discriminate between prospective basketball players in the talent screening process.

PURPOSE: to compare the performance level in each conditioning capacity category between elite and non-elite young basketball players over a 4-year period.

METHODS: 15 top-level male players participated in this retrospective study during four years (14-17 yr old) - guards [n=2], forwards [n=7], centers [n=6]. The subjects were divided into two different categories: II Elite (EI), athletes who play in the NBA, the First League of Spain (JACB) or on the Spanish National A Team (SNAT) [n=8]; III Non Elite (NE), players in the Second League of Spain (LEB) [n=7]. All the players participated in the same training program (5 h per day). Four times during each season each player performed various tests including countermovement jump (CMJ), Abalakov (ABK), horizontal jump (HJ), course Navette test (CNI), abdominal test [AT], strength explosive arm test [SEAT]. In addition anthropometrical data were recorded. The measures of each test were registered each season over the four year period and the best value of the first and last year was analyzed.

RESULTS: At the end of the training program the values were [Means±SD]. [Height: 198.4±5.0 vs. 197.2±4.3 cm, P<0.34]; [Weight: 89.7±10.5 vs. 91.7±3.9 kg, P<0.53]; [BMI: 22.52±2.0 vs. 23.4±0.7 Kg/m2, P<0.62]; [CMJ: 49.75±4.9 vs. 48.8±4.0 cm, P<0.17]; [ABK: 58.0±6.3 vs. 56.3±4.4 cm, P<0.06]; [HJ: 2.56±0.1 vs. 2.59±0.1 cm, P<0.53]; [CNI: 12.6±1.3 vs. 12.9±1.4 paliers, P<0.43]; [AT: 32.3±3 vs. 33.2±2 rpl, P<0.21]; [SEAT: 7.77±0.7 vs. 7.8±1.3 m, P<0.63], E and NE respectively.

CONCLUSION: Surprisingly, no statistically significant anthropometrical neither conditional capacities differences were identified between players that actually playing in NBA, ACB or SNAT and LEB players.

THE RELATIONSHIP BETWEEN PERCENT FAT AND 1500M TRACK RACE PERFORMANCE IN FEMALE ADOLESCENT RUNNERS

Kinoshita, N., Ogumo, Y., Katsukawa, F., Onishi, S., Yamazaki, H.

Keio University, Japan

Middle/long distance runners and their coaches often believe that runners must keep weight or fat mass as low as possible to run faster. In female adolescent runners, however, pursuing such a belief in excess would bring about harmful consequences to their health such as disordered eating, anorexia nervosa, or osteoporosis (female athlete triad).

To evaluate the relationship between fat percent (Fat%) and performance of running, we measured body composition by hydrostatic weighing among 18 female middle/long distance runners in a Japanese high school ranked in a high level in national competitions.

Body composition was measured twice in a year at the beginnings of pre- and peak-seasons and the measurement was repeated during 3 years of high school (from 15/16 to 17/18 years of age). The best record of 1500m track race of each season was selected from the results of several official races held in the respective season (T1500) and the best value of the first and last year was also determined (T1500best).

The first evaluation was performed in a preseason when the subjects entered the high school and height, body mass, and Fat% were 160.4+/−5.7 cm, 53.3+/−4.8 kg, and 14.1+/−7.8%, respectively. Although individual analysis of each year revealed that the subjects likely decreased Fat% and improved T1500.

RESULTS: At the end of the training program the values were (Mean±SD): [Height: 198.4±5.0 vs. 197.2±4.3 cm, P<0.34]; [Weight: 89.7±10.5 vs. 91.7±3.9 kg, P<0.53]; [BMI: 22.52±2.0 vs. 23.4±0.7 Kg/m2, P<0.62]; [CMJ: 49.75±4.9 vs. 48.8±4.0 cm, P<0.17]; [ABK: 58.0±6.3 vs. 56.3±4.4 cm, P<0.06]; [HJ: 2.56±0.1 vs. 2.59±0.1 cm, P<0.53]; [CNI: 12.6±1.3 vs. 12.9±1.4 paliers, P<0.43]; [AT: 32.3±3 vs. 33.2±2 rpl, P<0.21]; [SEAT: 7.77±0.7 vs. 7.8±1.3 m, P<0.63], E and NE respectively.

CONCLUSION: Surprisingly, no statistically significant anthropometrical neither conditional capacities differences were identified between players that actually playing in NBA, ACB or SNAT and LEB players.

PILOT PROJECT: TALENT DIAGNOSTICS AND DEVELOPMENT IN SELECTED SPORT ASSOCIATIONS

Habermann, N., Wollesen, B., Mattes, K.

University of Hamburg, Germany

Introduction: In June 2006 the interdisciplinary “Hamburg Talent Diagnostics and Development Program” - utilising sport scientific methodology - commenced. The talent diagnostics included a comprehensive physical ability test as well as a questionnaire regarding the athletes’ sport and training history. Eight selected sports associations (volleyball, field hockey, handball, basketball, badminton, track-and-field, soccer and rowing) were tested in the pilot project. The aim of the project was to analyse (1) the current state of the physical ability of the D-squad-athletes, (2) the identification of the athletes’ potential for development, (3) the requirement for career development and (4) as long-term assistance for their coaches.

Methods: 206 D-squad-athletes (age-group 1991-96) took part in the pilot project. The investigation included a normative questionnaire about the sport and training history and physical ability tests. The tests included: body composition (body height, body mass), flexibility, coordination and conditioning tests (areal orientation, shuttle run, 30m sprint, foot tapping frequency, speed related (jump strength, speed related throw strength) and sports specific tests. The data was compared with the normative data of C- and B- squad standard values. A correlation analysis was applied to verify the autonomy of the different tests.

Thursday, July 10th, 2008

14:15 - 15:15

ESPOIR/PORTUGAL, 09-12 JULY 2008

227
Results: The correlation showed that the tests were autonomous except the basketball throw correlated with body height (r=0.474), body mass (r=0.601) and BW (r=0.467). Foot tapping frequency correlated with the speed related jump tests (r=0.423), 30m sprint (r=0.479) and the shuttle run (r=0.490). The physical ability tests showed that only the hockey and handball sports associations were within the normative data. Sport specific normative data available for this age group is minimal.

Discussion: The pilot project “Hamburg Talent Diagnostics and Development Program” designed a manageable and practical approach to selective talent assessment. A comparison of the results of each individual within their sport and to the relevant normative data can then be available to coaches for discussion and analysis in reports and meetings. As a result, individual development tasks for each athlete were determined and operational guidelines formulated for each relevant coach. Through improved individual career development, competitive sport in Hamburg will be enhanced.

VARIATION IN STRENGTH TRAINING WITH NON LINEAR OR UNDULATING PERIODIZATION - A CRITICAL REVIEW

Stocker, S., Clijsters, R., Taneymans, J., Schmidtbiecher, D.
Akademie Physiotherapie, Switzerland

Designing a resistance training program is multifaceted. Non linear or undulating periodization has been a proposal of one possible procedure of strength training to improve maximal strength and muscular endurance.

Method: In this critical review, various studies are compared which includes non linear/undulating periodization as one of their parameters. Most studies compare groups which include variables which have a greater effect on maximum strength than the input of variation in an undulating training. Three out of four studies with equated volume and intensity didn’t show significant differences. Those three studies included bad males and women as subjects. One study revealed a significant increase in maximum strength compared to the other group but used trained males as subjects. Studies which included some sort of daily activity (e.g. carrying task) as their test parameters showed significantly better performances (nEMG efficiency) for the non linear group as compared to a linear group.

Conclusion: A higher maximum strength after a 6 to 12 weeks training period on non linear/undulating periodization was not observed compared to a linear periodization training concept, except on trained males and leg press only. A measurement on daily activity, testing the efficiency of the EMG muscle activity, is substantially better without increasing strength significantly. Functionality in sports such as a tennis serve improves significantly with a non linear program compared to a linear program without increasing maximum strength parameters at the same rate. Therefore the review leads to the conclusion that a non linear periodization training program might not increase maximum strength as much as expected but can be easily used to maintain strength and create a more interesting and challenging training program. It will work beneficiary in neurologically adaptations of muscle groups for skilled tasks in sports or everyday jobs.

HEART-FREQUENCY EXAMINATIONS OF PREMIER-LEAGUE MAN HANDBALL PLAYERS

Noé, J., Mocsai, L., Pavlik, G., Bosnyók, E.
Faculty of Physical Education and Sport Sciences of Semmelweis University, Hungary

Introduction: The European Championship for the Hungarian handball team this year in Norway did not yield the result we hoped for. Domestic sport experts have for long time the unanswered question: how could they make team sportsmen’s trainings more efficient and build in their individual cutted program onto their load cycle. The POLAR Team System is developed for objective measurement of team and individual performances. The trainer and the sports physician receive a steady feedback of the player’s match or training performances, development, overtraining-belowtraining, via the method of the pulse control. With the help of this system the sport expert can control the performance of 10-20 players on the court with laboratory accuracy. It becomes possible to form and execute an individually different training plan. The downloading of training’s data files to the POLAR analysing software is completely automatic and quick. The storage of all players’ training’s and application data, the test results, the pulse graphs and the training diary can be registered and managed in one place. The changes and developments can be calculated precisely. The tests are any time repeatable. After programming the chest signalling we can control the results and manage the performance data of each players with thorough analysing by the software.

Objective: To improve the match and training efficiency of teammates especially of international leading men handball players development of individually training plans and sport-art specific test system.

Method: A continuous heart frequency monitoring with the help of the POLAR Team System, making videos and taking notes on matches and trainings, the precise and objective analysis and assessment of these materials. Accomplishment and repetition of antropometric measurement, body combination examination, relative VO2, “pendulum-test” for stamina, and specific (f. e.: “loop-test”) tests. Anaerobic threshold value definition with lactate measuring. The results of the measurements are processed by POLAR Precision Performance, MS Excel and Statistica 7.0 Softwares.

Results: We have collected, registered and aggregated the training data of several months of 20 premier league and 15 third league handball players. These data informed the sport expert of his/her player’s actual state, actual and longer-term performance, working ability, individual load zone, test results. The improvement of the player’s performances was already demonstrable in the preparatory section in the course of experiments. The player’s got motivated improving their individual performances to create a more successful team play.

Inference: The measurement’s results show that most problems can be leaded back onto incongruent coordination, few work with aerobic character, deficiency of stretching. “Tired” musculature and heart circulation system can be the reasons of potential failures first of all of the inadequate match performance For the qualitative change o

EFFECT OF PASSIVE STRETCHING ON STRENGTH: A SYSTEMATIC REVIEW

Bosquel, L., Pearson, H., Arvisais, D., Shrier, I.
UNIVERSITY OF MONTREAL, Canada

Purpose: The purpose of this investigation was to assess the effects of passive stretching on the different components of strength, through a meta-analysis.

Methods: We searched six databases using relevant terms and strategies. Criteria for study inclusion were: a stretching intervention must be employed providing details about the procedures (duration of each stretch, delay between the last stretch and the
performance test and the outcome had to include performance tests of strength or power, inclusion of all necessary data to calculate effect sizes. Data sets reported in more than one published study were only included once in the present analyses. Initial search provided 266 studies of which 107 titles were potentially relevant and screened for retrieval. Of these, 59 studies met the inclusion criteria and were included in the meta-analysis. We conducted separate analyses for voluntary maximum voluntary contraction (IWVC) and power (jump tests) using the independent variables stretch duration, delay between the last stretch and the performance test, sex, and physical activity level. Standardized mean differences (SMD) in MVC or power were calculated, and weighted according to the within-group heterogeneity to develop an overall effect estimate. We compared subgroups using the Chi-squared (Q) test. Results: Passive stretching significantly decreases MVC (SMD [95%CI] = -0.21 [0.35 to -0.07], p = 0.003), but not maximal power (SMD [95%CI] = -0.06 [0.17 to 0.05], p = 0.28). The duration of the delay between the last stretch and MVC (less than 5 minutes; from 5 to 15 minutes; from 15 to 30 minutes; more than 30 minutes) did not affect the results (Q = 2.88, p = 0.41), nor did sex (Q = 0.91, p = 0.34). However, stretching had a lesser effect as physical activity increased (comparison of subgroups Q = 6.18, p = 0.04). Stretching decreased maximal voluntary strength more in sedentary (95% CI = -0.40 [-0.70 to -0.11], p = 0.008) and active individuals (95% CI = -0.10 [-0.23 to 0.02], p = 0.10). Conclusion: There is a growing consensus that passive stretching decreases performance during strength and power tests. The main result and contribution of this study is to underscore the heterogeneity of this acute response. Passive stretching significantly decreased MVC, but the decrease in power was not statistically significant. This effect is independent of sex and duration of the delay between the stretching procedure and the strength measure, but it is much more important in sedentary and active individuals compared with athletes. This meta-analysis provides a framework that can be useful for athletes to optimize their warm-up strategy, but also for scientists to understand the mechanisms underlying the heterogeneity observed between sedentary, active and highly trained individuals.

THE CONTROL MODEL OF PHYSICAL FITNESS AT THE NATIONAL ARMED FORCES OF LATVIA

Labalaiks, Z., Dravnieks, J.
Latvian Academy of Sports Education, Latvia

Properly worked out physical fitness norms motivate every soldier to go in for sports activities regularly in order to maintain his physical condition on adequate level. It is an essential precondition for successful performance of military service duties. Physical fitness evaluation system should reflect the real situation - real physical condition of the tested people. Physical fitness evaluation system should be adequate, objective and developing versatility. Equal evaluation points should be given for equal difficulty level results in different tests. Physical fitness norms should promote development of soldiers' physical fitness. Elaborating the point tables (data tables) according to the S-type (percentile) scale, we may have an adequate assessment of equal difficulty level results in various tests. The sum of the points gained by performing a set of tests is used for the evaluation of physical fitness by giving a mark or a certain physical fitness category according to the norms - previously stated sum of point values. Physical fitness norms are the most significant block of physical fitness control system - a mechanism which promotes the development of many-sided, harmonious and physically fit people. In order to prepare soldiers of the Latvian NAIF for professional military service it is essential to evaluate the current physical fitness of soldiers, its control system and, if required, to change the system. Taking the conclusions drawn from the analysis of the physical fitness test results as the basis the physical fitness and condition control system model is being worked out. Having the test result data of the statistical analysis and approximating the gained results in the percentile scale to standard distribution cumulative function the S-type point table was constructed for each test. By offering the new point table model, we foresee significant changes, as well as radically changed physical fitness norms for Latvian soldiers.

OBSERVATIONAL METHODOLOGY: T-PATTERNS DETECTION IN SOCCER

Leitão, J., Martins, N., Oliveira, C., Campanção, J., Almeida, J.
University of Vila Real, Portugal

Several traditional soccer analyses essentially show quantitative data (frequency of shots on goal, distribution of player’s passes...). But not the context where the actions (interactions) are developed. In this sense, the purpose of this study is to detect and analyse t-patterns when the attempt to score occurs. The sample is formed by 47 games of the Korea/Japan 2002 FIFA World Cup, where 55 free kicks and 285 cross plays were coded to sequential analysis with TH-HEME 5.0 (T-Pattern). One complete t-pattern was detected in free kick plays and seventeen in cross plays pointing to the importance of the initial conditions (first event of sequential structure) and the game non-linearity. However, when teams score the results only reveal incomplete t-patterns showing its importance is in free kicks to aim for the top corners without course changes if the efficacy of the shots to the low corners and cross play’s from the wings.

RELATIONSHIP BETWEEN DISCUS PERFORMANCE AND USING THE TORSO ROTATION ACTIVITY DURING DISCUS THROWING

Aoyama, S., Kobayashi, S., Aoyama, T., Tsunoda, N.
University of Kokushikan, Japan

In discus throw, it is very important to clarify the relationship between discus performance and using the torso rotation activity during discus throwing. The subjects were nine male Japanese discus throwers including Japanese top throwers (age:20.8±21.9yrs, height:179.6±5.8cm, body weight:93.6±10.7kg, fat free mass: 74.0±5.4kg, personal best:48.10±5.0m). Using the torso rotation activity was performed subjects face up position on the ground, and put the balance ball (a diameter of 60cm) in between both legs, was relaxing upper body including cervix. Using the torso rotation activity on right and left side with balance ball was performed by ten times after the third throw (before), and then after the other three throw (after). It was same as an official competition for six throws. Discus performance was adopted average of three throw in before and after using the torso rotation, and best throw of three throw in before and after using the torso rotation. Discus throw movement time was filmed by digital video camera at 1/250s and 60 frame/s(FMV-Canon). The results were as follows: Average of Discus performance was improved with using the torso rotation activity 41.7±4.68m to 42.35±5.13m. And also, best of discus performance was improved with using the torso rotation activity 43.39±4.64m to 44.45±5.15m.
Discus performance in after using the torso rotation activity was significantly higher than before using torso rotation activity (p<0.05).

Discus throw movement time was not so differed between before using the torso rotation activity (1.56±0.18sec) and after torso rotation activity (1.56±0.17sec). It was no significant differences between discus performance and discus throw movement time.

In this study, discus throw movement time dose not influence to discus performance, whereas the using torso rotation activity during discus throwing was influential to the discus performance. In addition, it is suggested that throwers needed to torso rotation training. From these finding, it is considered that in discus throw, using the torso rotation activity during discus throwing and developing torso rotation training can be factors of improved at discus performance.

FAMILIARIZATION, RELIABILITY, AND COMPARABILITY OF A 40 M MAXIMAL SHUTTLE RUN TEST
Glaister, M., Hauck, H., Abraham, C., Merry, K., Beaver, D., Woods, B., McInnes, G.
St Mary’s University College, United Kingdom

The aims of the present study were to examine issues of familiarization and reliability associated with a 40 m maximal shuttle run test (40 m MST), and to compare performance and associated parameters in the test with those of a typical unidirectional multiple sprint running test. 16 well-trained subjects (12 men and 4 women) completed four trials of the 40 m MST (8 × 40 m; 20 s rest periods) followed by one trial of a unidirectional multiple sprint running test (12 × 30 m; repeated every 33 s); with seven days between trials. All trials were conducted indoors and performance times were recorded via twin-beam photocells. Means ± standard deviation for age, height, and body mass were 20 ± 2 years, 176.5 ± 9.7 cm, and 72.6 ± 11.2 kg, respectively. Significant (p < 0.05) between-trial differences in mean 40 m MST times were indicative of learning effects between trials 1 and 2. Test-retest reliability across the remaining trials as determined by coefficient of variation (CV) and intraclass correlation coefficient (ICC) revealed: a) very good reliability for measures of fastest mean and mean shuttle time (CV = 1.1 - 1.3%; ICC = 0.91 - 0.92); b) good reliability for measures of blood lactate (CV = 10.1 - 23.9%; ICC = 0.74 - 0.82) and ratings of perceived exertion (CV = 5.3 - 7.6%; ICC = 0.79 - 0.84); and c) poor reliability for measures of fatigue (CV = 38.7%; ICC = 0.59). Comparisons between performance indices of the 40 m MST and the unidirectional multiple sprint running test revealed large (r > 0.5) significant (p < 0.05) correlations between all measures apart from pre-test blood lactate (r = 0.47). Whilst the 40 m MST does not appear to provide any more information than can otherwise be gleaned from a typical unidirectional multiple sprint running test, the results of this study show that following the completion of a familiarization trial, the 40 m MST provides an alternative and, except for fatigue measures, reliable means of evaluating repeated sprint ability.

PROPOSITION TO TEST SOCCER PLAYERS FOR MAXIMUM AEROBIC POWER
Darlos, L., Osecki, R., Dourado, A., Stanganelli, L., Fornazieri, A.
1)Middle-West Stade of Paraná University, (2) Federal University of Paraná, (3) State of Londrina University, Brazil

This present study has as objective to develop a maximum aerobic power test, specific to application on soccer athletes, and to propose an equation to estimate VO2 max, through a field test developed. The proposed test constitutes of applying progressive, continuous and maximum speed running, covering 80m (1 lap), structured in a square (20m x 20m), test initial speed was 11.5 km/h, with speed increments of 0.5 km/h each minute, where the athletes should perform up to exhaustion. For measuring velocity in field test the CD test of Yo-yo endurance II proposed by Bangsgaard (1996) was used. As gold standard to compare the field test a treadmill test was carried out with initial velocity of 8 km/h with 1 km/h increments each minute up to the exhaustion. To obtain measures referred to VO2max a portable device of ergospirometry K4b2 was used in treadmill tests as well as in field tests and to analyse the blood lactate the ‘Yellow Springs 1500L’ equipment was used. The variables studied on both tests were VO2max, FCmax, respiratory quotient, minute ventilation, distance covered, maximum speed reached, total test duration time and final lactate after three-minute active recovery. Twenty four soccer athletes under-18 and under-21 were evaluated, aging 16.66±1.49 years, body mass of 71.5±8.28, height of 177.07±0.82 and BMI of 22.74±1.28. The following procedures were carried out to analyse the data: descriptive statistics, t Student test, Pearson’s correlation and Simple Linear Regression Analysis using the statistical program SPSS13.0, considering a significance level of p<0.05. The results found show no significant difference between treadmill test and the proposed test, for the variable VO2max (treadmill 30.19±5.09 and field 48.55±6.56; p<0.077). High correlation was found between field VO2max with distance covered in field (r=0.768; p<0.000) and with maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000). Thus, it was possible to establish two predictive equations through variables of distance covered and maximum speed reached: VO2max = 21.829 + 0.015 x Distance covered and VO2max = -65.275 + 7.536 x maximum speed reached in the field test (r=0.737;p<0.000).

OPTIMAL WARM-UP STIMULI OF MUSCLE ACTIVATION TO ENHANCE SHORT AND LONG-TERM ACUTE JUMPING PERFORMANCE
Saez-Saez de Villarreal, E., González-Badillo, J., Izquierdo, M.
University Pablo de Olavide, Spanish Olympic Center of Sport Studies, Research, Studies and Sports Medicine Center, Government of Navarra, Spain

The aim of this study was to determine the effect of different types of active warm-up stimuli of muscle activation on explosive jumping performance after short 15 minutes postwarm-up and long 16 hours postwarm-up recovery periods following warm-up. Twelve trained volleyball players [21-24yr] performed different types of specific warm-up stimuli (WP) after baseline measurements (e.g. countermovement jump (CMJ) without and with extra load and Drop jump (DJ) on randomized separate occasions: 113 sets of 5 jumps with extra load (WP1), 212 sets of 4 reps at 80% of 1RM parallel-squat (WP2) and 2 sets of 2 reps at 85% of 1RMPS (WP2), 312 sets of 4 reps at 80% of 1RMPS and 2 sets of 2 reps at 90% of 1RMPS and 2 sets of 1 rep at 95% of 1RMPS (WP3), 413 sets of 5 DJS (WP4), 5 specified warm-up for a volleyball match (WP5), 613 sets of 5 reps at 30% of 1RMPS (WP6) and 7) an experimental condition of no active warm-up. Height in DJ significantly improved (p<0.05) after WP1 (4.18%), WP2 (2.98%), WP3 (5.47%) and WP4 (4.49%). Maximal power output during CMJ with extra load significantly improved (p<0.05) after WP2 (11.39%), WP3 (10.90%), WP3 (9%) and WP1 (2.47%). High-intensity dynamic loading (e.g. 80-95% 1RM), as well as specific volleyball warm-up protocol bring about the greatest effects on subsequent neuromuscular explosive
responses. Acute positive effects on jumping performance after warm-up were maintained after long recovery periods (e.g., 6 hours following warm-up), particularly when prior high-intensity dynamic actions were performed.

**HEART RATE THRESHOLD OCCURRENCE AND STROKE VOLUME PERFORMANCE DURING 1-MIN RAMP TEST IN CYCLISTS**

Lepretre, P.M., Lopes, P.
(Iнститут National des Sports et de l’Education Physique, France)

In 1982, Conconi et al. presented a non-invasive method for the determination of anaerobic threshold (AnT) based on the occurrence of a break point in the heart rate - physical work curve, so called “heart rate deflection point” (HRDP). However, its application is limited because the HRDP appearance would be protocol dependent (Jones et al. 1997). Furthermore, the physiological explanation of the HRDP is still lacking. Recently, Lepretre et al. (2005) found a significant correlation between the power at which the HRDP appeared (pHRDP) and the power at which the stroke volume (SV) reached its maximal value (pSVmax) in 72.7% of 22 well-trained subjects engaged in an exhaustive 3-min stage incremental cycle exercise. In addition, a protocol effect on SV responses has also been reported in trained subjects engaged in different maximal graded exercise tests (McCole et al. 2001). Therefore, this examines the effect of exercise protocol on the relation between heart rate, stroke volume appearance and SV response in ten well-trained male cyclists (20.9±6.1 yrs, VO2max: 67.6±5.7 mL·min−1·kg−1 and power at VO2max: 365±38 watts). An incremental exercise test (2-min warm-up at 60 watts then 25 watts min−1 until exhaustion) was performed in an upright position using an electromagnetically braked cycle ergometer (Ergoline BP-900, Schiller, Germany) to determine: 1) the maximal oxygen uptake value (VO2max, 2) the power associated with the anaerobic threshold (pAnT), and 3) the heart rate (HR) and stroke volume performance curves. HR and SV values were continuously measured by impedance towards the end of exercise (Charloux et al. 2000). In all subjects, the arterial-venous O2 difference increased up to pAnT (corresponding to 83.0±3.8% of pVO2max).

A HRDP, estimated by a third order curvilinear regression method (Kara et al. 1996), appeared in 80% of the subjects at about 82.5±9.3% of their pVO2max (n = 13). In 4 of these subjects, SV reached a plateau at the intensity of which HRDP appeared whereas it increased until pVO2max for 4 others. However, this SV increase from pHRDP to pSVmax was not significant. Moreover, pHRDP was not significantly different from pAnT. Any significant effect of the protocol was found on relationship between the HRDP occurrence and SVmax during incremental exercise to VO2max. Our data also indicates that the factors influencing the SV response to exercise could subject dependent with VO2max limited by central (evidence of SV plateau) or peripheral factors (continued increase in SV until VO2max).

**THE CLUSTERING OF PHYSIOLOGICAL RESPONSES AMONG ELITE ATHLETES FROM DIFFERENT SPORTS**

Ruzic, L., Heimer, S., Mikulic, P.
Faculty of Kinesiology, University of Zagreb, Croatia

The athletes engaged in the events of longer duration and lower intensity would use different energetic pathways than the events of shorter duration and high intensity, resulting in specific physiological adaptations after years of training. Many authors suggest that some adaptations may be limited by genetic make-up or heredity. The aim of the study was to determine whether all elite athletes coming from the same energetic group (aerobic, anaerobic or mixed type sports) manifest the same physiological response during physical load and to determine whether the traditional classification of the sports according to the energetic demands could be applied to them. The sample comprised 102 elite athletes divided into 3 groups (Group 1: aerobic sports, Group 2: aerobic/anaerobic sports, Group 3: anaerobic events). Morphological variables, explosive strength, and ventilatory parameters during incremental treadmill test (Vo2max, HR at ventilatory threshold, VO2max, VO2 at threshold, VE at threshold, expired CO2 at maximum, RERmax) were measured and the percentages of maximal VO2, HR, CO2 and VE at the ventilatory threshold were calculated.

1st step: The discriminative analysis confirmed that the traditional classification of sports according to the energetic pathways was reasonable when applied to total sample. The three groups of athletes really differed significantly (Wilks’ lambda=0.350, p<0.001). The variables that contributed the most to the discrimination of the groups were VO2max, VO2 at ventilatory threshold, and % of VO2 at ventilatory threshold, all of which were higher in aerobic athletes. RERmax and explosive strength were lower in aerobic athletes as expected.

2nd step: We tried to determine whether the statistical analysis would divide the subjects into the same groups as we did according to the energetic demands of the sport. The k-means cluster analysis was used and it confronted the previous findings in a way that it extracted the entities that were really different from other members of their group. The number of subjects in the newly obtained groups was different from the number in our groups, which clearly pointed to mixing of the subjects among the groups. Even though their ventilatory parameters, explosive strength and aerobic capacity was not as it was expected for that type of sport they were still the top athletes in their sport. The most interesting findings were the results of several aerobic athletes whose functional response was similar to the athletes in anaerobic group and despite that they won several international competitions shortly after. It was interesting that the years of aerobic training did not result in expected adaptations which might be explained by heredity. In conclusion, individual differences originating from genetic and psychosocial factors should always be considered before evaluating testing results, especially during the selection process.

**THE DYNAMICS OF SPEED OF THE 400M SPEED RACE JUNIOR ATHLETES (18 YEARS)**

Gevat, C., Lariou, A., Popa, C., Dragomir, L.
Ovidius University of Constanza, Romania

The transversal study points to the fact that during the 400m speed race, indoor, junior athletes 1st category, the greatest speed loss can be noticed in the interval between 200-300m. The selection of the subjects was made on the basis of their enrollment in the 400m event. Date analysis have been recorded during the Athletics National Championship, juniors (boys) 1st category, on February 26-27, 2005, Bucharest. The study’s hypothesis presupposes that the greatest loss of speed in the 400 m indoor, juniors race 1st category (18 years) in Romania is on the last 100m, fact that was not confirmed. During the first 100m of the 400m race, the 15 boys have recorded medium speed 7.83m/s±0.19 (CV%=2.82). In the second 100mp of the race medium speed was 8.18±0.30 (CV%=3.66). In conclusion, any significant effect of the protocol was found on relationship between the HRDP occurrence and SVmax during incremental exercise to VO2max. Our data also indicates that the factors influencing the SV response to exercise could subject dependent with VO2max limited by central (evidence of SV plateau) or peripheral factors (continued increase in SV until VO2max).
A KINEMATIC ANALYSIS OF NETBALL GOAL SHOOTING: COMPARISON BETWEEN JUNIOR AND SENIOR PLAYERS

Delextrat, A., Goss-Sampson, M.
London Metropolitan University, Greenwich University, United Kingdom

Introduction
Only two experimental studies have investigated the relationship between shooting accuracy in netball and anthropometric and kinematic parameters of the dominant side of the body. Shooting accuracy was positively related to better wrist flexibility, greater angle of knee and elbow flexion in the preparatory phase, lesser movements of the trunk and arm during the shot, and greater height and velocity at release (Elliott and Smith, 1983a,b). The aim of this study was to investigate the effect of playing age and experience on the kinematic characteristics of the dominant and non-dominant sides of the body during the goal shooting action in netball players.

Methods
Six county-level junior and six senior goal shooters took part in the study. All subjects performed eight shots at the goal during which thirty-three 19 mm retro-reflective markers were fixed to anatomical landmarks for segment identification and 3D motion tracking. Kinematic data were captured at 200 Hz using a 10 camera (M CU240 ProReflex) retro reflective motion capture system (QTM, Qualysis, Sweden). The shot was divided in three periods: preparatory phase, shooting action and release, the following variables were analysed during each period; ball position, joint angles, angular velocities and timings. Differences between junior and senior shooters were analysed by a non-parametric Mann-Whitney test. The level of confidence was set at P<0.05.

Results
Compared to the senior players the juniors exhibited a significantly greater extension of the non-dominant arm during the preparatory phase (angles at the elbow of 139.1±19.4° vs. 106.8±25.1° for juniors compared to seniors, P<0.05), reduced synchronisation between knee and elbow extension during the shooting action (time between the start of knee extension and elbow extension of 0.15±0.03 s vs. 0.04±0.05 s respectively for juniors and seniors, P<0.05) and a greater extension of the non-dominant elbow and shoulder at release (angles at the elbow and shoulder were 153.3±16.9° and 150.5±11.1° vs. 121.5±32.5° and 121.0±28.9° for juniors compared to seniors, P<0.05).

Discussion-Conclusion
These results could be useful for coaches to understand the technique used by shooters at different learning stages. In particular, recommendation to junior less skilled players should focus on the synchronous actions of the elbows and knees and dissociation between the right and left upper limbs during the shooting action.

PHYSIOLOGICAL DEMANDS PLACED ON FEMALE BASKETBALL PLAYERS DURING COMPETITION

Delextrat, A., Matthew, D., Cohen, D.
London Metropolitan University, United Kingdom

Introduction.
In May 2000, basketball rules changed (shorter attack time from 30 to 24 s and less time allowed to cross the median line from 10 to 8 s). Ben Abdelkrim et al. (2007) measured heart rate (HR), blood lactate ([La]-b) and time motion analysis of elite under-19 male players during competition and reported that the new rules led to an increase in the game intensity and a higher cardiac work. The aim of the present study was to investigate if the new rules of the game have also changed the metabolic load experienced by female players competing at a lower level.

Methods
9 female university basketball players (25.8±2.5 years old, 172.8±4.7 cm, 63.2±4.5 kg, 19.9±3.4% of body fat) were studied during 9 games in the premiership league. During each game, HR was measured at 15-s intervals using Polar S810 heart rate monitors (Polar, Kempele, Finland), blood samples were taken to analyse [La]-b between quarters, during timeouts, or during player substitution (Analox Instruments Ltd., London, UK). In addition, video recordings of matches (VVC-x400 Hong Kong, China) were used to determine the frequencies of the main movements performed by the players, as defined by McInnes et al.2. Differences in physiological parameters between the quarters and halves of the game were analysed by a one-way ANOVA and a student T-test for paired samples, respectively. Statistical significance was set at p<0.05.

Results
51 HR files and 111 blood sample were obtained. The mean HR was 165.0±9.0 beats.min⁻¹ (89.8% of HRmax) and the mean [La]-b was 5.2±1.7 mmol.L⁻¹ (45.9% of [La]-bmax). In addition, HR was significantly higher in the first half compared to the second half (166.3±9.4 vs. 163.3±9.0 beats.min⁻¹, P<0.01), whereas no significant effect of time was observed on [La]-b (P>0.05). Video analysis showed that players performed on average 52±14 jogs, 56±11 runs, 32±13 sprints, 69±18 low-intensity shuffles, 58±15 medium-intensity shuffles, 43±16 high-intensity shuffles and 42±11 jumps.

Discussion-Conclusion.
These results show a significantly higher HR compared to the values reported in male players before the rule changes (87% of HRmax, McInnes et al., 1995), and similar to the HR measured in male and female players after the new rules (91% of HRmax and 90.8% of HRmax, respectively in the studies of McInnes et al., 1995 and Rodriguez-Alonso et al., 2003). They suggest an increase in physiological demands of university-level female basketball players after the new rules.

CROSS-VALIDATION OF THE KHAMIS-ROCHE METHOD FOR THE PREDICTION OF MATURE HEIGHT

Coelho e Silva, M., Moreira de Carvalho, H., Vaz, V., Romaine, J., Figueiredo, A., Malina, R.
University of Coimbra, Portugal

Several non-invasive methods have been proposed for the estimation of maturity status in youth. The purpose of this paper is to compare percentage of predicted mature (adult) height at a given age with percentage of mature height based on attained mature (adult) height. The sample included 80 youth hockey players 14.8-16.5 years who were measured in 2002 (Sept-Oct). Height and weight were measured using a portable stadiometer (Harpenden) and a portable balance (Seca model 770) to the nearest 0.1 cm and 0.1 kg, respectively. Maturity height was predicted after Khamis and Roche (1994) using age, height and weight and midparent height. Heights of both biological parents were measured. Current height of the player was expressed as a percentage of predicted mature height. Heights of the players were measured again in 2006 (Sept-Oct) providing a measure of attained mature height. Heights of the players as teenagers were then expressed as a percentage of attained mature height.

The difference between predicted and attained adult height was 0.9±0.196 cm (median: 1.20 cm, range: 3.7 to -4.0 cm). Of interest, the difference was, on average, less in 15 year old (10.3±1.98 cm) than in 16 year old (13.4±1.85 cm) players. Teenage height was 171 2±6.3 cm (G1: 15 yrs) 168±5.9 cm; G2: 16 yrs: 172±8.6 cm) compared to attained mature height, 175±5.2 cm (G1: 174±5.1 cm; G2: 176±5.2 cm). Teenage height represented 98.0±1.6% of predicted mature height (G1: 96±1.5%; G2: 97±1.2%) and 97±1.4% of attained mature height (G1: 96±1.5%; G2: 97±1.1%). The correlation between measured and predicted adult height was r=0.93 (G1: +0.92, G2: +0.94), while the correlation between current height as a percentage of predicted mature height and as a percentage of attained mature height was +0.75 (G1: +0.73, G2: 0.61).

The results indicate that the Khamis-Roche protocol for the prediction of mature (adult) height without a measure of skeletal age has reasonable validity in this sample of Portuguese adolescents and can be used to derive current height as a percentage of adult predicted mature height as a non-invasive estimate of biological maturity status.

SKILL IMPROVEMENT FOR AN ELITE BACKSTROKE SWIMMER AS DETERMINED WITH A SPEED METER

Tanaka, T., Yoshimura, Y., Yasukawa, M., Oishi, K.
Tokyo CRO, Inc., Japan

A speed meter that measures a subject’s moving velocity by pulling a fine wire over a generator (Maglisch, 2003) for a distance of 25m was developed for use with competitive swimmers. In a previous study, the authors used the speed meter to check for skill differences between competitive breaststroke swimmers of international achievement and collegiate breaststroke swimmers. Additionally, the speed meter was used to measure improvement in underwater dolphin kicking for a backstroke swimmer who made very rapid progress. These results showed that this method was useful for identifying skill differences among a group of swimmers as well as reasons for improvement for each swimmer. In the present study, the authors used the speed meter to determine the degree of skill improvement during the underwater stroke phase for an elite backstroke swimmer. This was compared with the amount of improvement in his performance over a period of two years. The speed meter recorded his intracyclic velocity changes during a 25m maximum effort backstroke swim which included approximately 12m of underwater dolphin kicking. An underwater video analysis system was also used to check his stroke techniques during these efforts. Based on the video data, the authors divided the stroke cycle into two phases, i.e., 1) first downsweep and upsweep phase, and 2) second downsweep phase. The mean velocities for the second downsweep phase were similar despite improvements in the athlete’s performance times (Joncheere-Terpsstra Test, p=0.0562). However, the mean velocities for the first downsweep and upsweep phase became higher as performance improved (Joncheere-Terpsstra Test, p=0.0053). It was concluded that the first downsweep and upsweep phase was the most improved portion of this swimmer’s underwater stroke and, therefore, primarily responsible for his improved performance.

PREDICTION OF SUCCESS IN VOLLEYBALL THROUGH ANTHROPOMETRIC, PHYSIOLOGICAL AND PSYCHOLOGICAL CHARACTERISTICS

Afzalpour, M., Rashidi, E., Keshtidar, M.
1-Islamic Azad University, Birjand Branch, 2-Islamic Azad University, Khashmar Branch, 3- Birjand University, Iran

The purpose of this study is to determine linear regression between anthropometric, physiological, psychological and skill-related characteristics of volleyball players in South Khorasan Province, Iran. Forty five volleyball players participated in this study. Anthropometric, physiological, psychological, and skill-related characteristics of subjects were measured using methods including Storer and Davis maximal test, Wingate test, strength test, Zigzag test, floor push-ups, Winter’s questionnaire and the AAHPERD skill-related test for volleyball. To analyze the data we used Pearson correlation coefficient and linear regression test through Stepwise method and, statistical significance was considered where P<0.05. A significant correlation was noticed between the subjects’ height, weight, trunk height, humerus diameter (HD), motivation, group type, experience in volleyball (EV), muscular strength and endurance, agility, anaerobic peak power (APP), concentration, and their service skill (P<0.05). In addition, there was a significant correlation between the subjects’ height, body mass index, flexibility, APP, motivation, group type, EV, weight, calf circumference, muscular strength and endurance, agility, concentration, and their overhead pass skill. Moreover, a significant correlation was obtained between the subjects’ flexibility, experience of parents in sport, group type, EV, grip strength, trunk muscles endurance, agility, concentration, and their pass skill (P<0.05). Besides above, it is established a significant linear correlation between the subjects’ weight, HD, agility, back strength, concentration, and their service skill, and a significant linear correlation between the subjects’ agility, concentration, targeting and their pass skill (P<0.05). The results show that EV, age, grip strength, overhead pass and service skills are good criteria to distinguish subjects and their success levels. It is, therefore, possible to predict success in volleyball through players’ anthropometric, physiological and psychological characteristics.

References.
The subjects of the study were 18 male high-level athletes from predominantly aerobic sports athletics (middle distance runners), orienteering and biathlon. A maximal treadmill stepwise test until exhaustion was performed with continuous breath-by-breath gas analysis. VTRER was defined at the level of RER=1.0, VTEqO2, VTV-slope and RCP were determined with a linear regression analysis. For all methods the corresponding values of physical power (PP) and oxygen consumption (VO2) at VT were analyzed. The obtained values for VTEqO2, VTV-slope, VTRER and RCP were statistically processed with one-way ANOVA-test and pairwise comparison analysis (Student’s t-criterion). Despite the presence of criteria verifying maximal exertion, in 3 of the tested subjects RERmax was below 1.0, thus, not allowing determination of VTRER. These subjects were excluded from the statistical analysis. In the One-Way ANOVA test a significant difference was demonstrated between the values of VO2 (ml/min) and PP (MET) corresponding to the determined VTRER, VTEqO2, VTV-slope and RCP (F=7.95 and F=14.53; p<0.05) in the pairs VTV-slope-VTRER, VTV-slope-RCP, VTEqO2-VTRER and VTEqO2 RCP. The multiple pairwise comparison analysis for VO2 and PP revealed the following values for r, t and p: VO2 to VTRER r=0.646, t=4.86; p<0.05; VTRER to RCP r=0.955, t=1.41, p=1.03.

The conducted analyses demonstrate a lack of statistically acceptable interchangeability between VTRER as compared to VTV-slope and VTEqO2. The differing results obtained for VTRER probably depend on which of the 3 methods for its determination is applied the classical method (using the breakpoint of the nonlinear increase of RER), VTRER at RER=0.95 (3) or VTRER at RER=1.0 (4).

In some high-level athletes with RERmax <1.0 VTRER (RER=1.0) cannot be used which requires further investigations on the criteria for VTRER determination.

DEVELOPMENT OF SPORTS TALENT SEARCH SYSTEM FOR KOREAN YOUTH
Byounggoo, K., Bonjgu, S., Haimo, G., Hongsun, S., Sungwon, Y., Dongsik, C., Juhak, K., Seungyun, S., Kyoungtaek, C., Yeonsung, C.
Korea institute of sport science, Korea, South
The purpose of this study was to develop sports talent search system that can easily assess potential of Korean youth in 23 sport events and to identify sport talents who have high potential in track-and-field, swimming and gymnastics. Physique, fitness, motor ability, physiological and psychological tests were administrated. Data of 407 elite athletes, 249 university students and 2,406 youths who aged 7 to 15 were collected.

Using standardized process of differences between elite athletes and university students in each test result, the profiles of elite athletes in 23 sport events were made. Based on these results, the evaluation program for assessing potential of Korean youth in each sport was developed.

Finally, sports talent search system for Korean youth that has 3 stages was developed through web based computer programming. The function of stage 1 is searching for youth who have reached certain criterion on physique and fitness test that were already administrated in schools. The function of stage 2 is informing best suitable sports and determining candidates for sports talent in each sport event through assessing test results on physique, fitness and motor ability that would be administrated in regional sports talent centers. And the function of stage 3 is identifying sports talent through assessing the results on physiological tests, psychological tests and basic movement performance test which is related to track-and-field, swimming and gymnastics that would be administrated in central sports talent center.

The sports talent search system would contribute to identify talented youth in sports among Korean youth population and success for international sports competition.

THE HEART RATE RESPONSES AND REPRODUCIBILITY OF SMALL-SIDED RUGBY LEAGUE GAMES
Foster, C., Twist, C., Nicholas, C., Lamb, K.
University of Chester, United Kingdom
Small-sided games (SSGs) are an effective aerobic interval training method used in soccer (Impellizzeri et al., 2006) and rugby league (Gabbett, 2006). The framework of 4×4 minute high intensity bouts of 90-95% maximal heart rate (HRmax) has been incorporated within SSG research as this interval format has been shown to increase maximal oxygen uptake (VO2max) (Helgerud et al., 2007), while also providing an ecologically valid training method (Impellizzeri et al., 2006). Furthermore, heart rate (HR) responses to SSGs have been shown to be sensitive to the playing area size and player number in soccer (Owen et al., 2004). Therefore, the purpose of this study was...
to examine the effects of altering playing area size and player number on the intensities (HRs) elicited by elite junior players during rugby league SSGs.

Following ethical approval, 14 junior players from a professional club (mean age: 15.5 +/- 0.5 y; stature: 179.6 +/- 5.1 cm; body mass: 76.7 +/- 10.2 kg; V02max: 52.2 +/- 5.5 ml/kg/min; HRmax: 196 +/- 9 b/min) volunteered to participate in the study. HR responses were recorded in separate 4v4 and 6v6 offside touch games (adapting the same rules), randomly played across two trials of three different sized areas; 15x25 m (small), 20x30 m (medium) and 25x35 m (large).

A three-way ANOVA with repeated measures indicated that there was a significant main effect of player number (F = 40.4, P< 0.05), with mean HR being higher in the 4v4 (90.6% HRmax) than the 6v6 SSGs (86.2% HRmax). The variability due to trials was not significant (F = 1.9, P>0.05), nor was the effect of playing area size (mean HRs of 89%, 88.8% and 87.4% of HRmax in the large, medium and small playing areas respectively). The player number x area size x trial interaction was significant (F = 40.4, P< 0.05), though this was solely due to significant (P<0.005) variability occurring between trials in the small 6v6 SSG.

Intraclass correlation coefficients (ICC) indicated that the 4v4 medium grid was the most reliable SSG condition (ICC = 0.91) with all other ICCs ranging from 0.54-0.73. The 95% limits of agreement (LoA) showed good agreement between trials, particularly in the 4v4 medium condition, whereby the HR variation was only 2.6% of the overall mean of the two trials.

This study’s findings demonstrate that these SSGs generate high HR responses, the highest being elicited in the 4v4 games (above 90% HRmax) independent of the size of the area used. Moreover, the medium 4v4 SSG condition was found to be the most reproducible size in terms of HR responses. It is recommended that rugby coaches take account of these factors when adopting SSGs for aerobic training.

References:
energy in the pole by bending it, using the energy recall from the pole to increase the potential energy of the centre of gravity and to add muscular work to maximize jumping height. However the quantitative distinction between the athlete’s energy and the energy of the pole was not done.

Improvements of the technical equipment allowed to analyse (within reasonable work load limits) pole vault kinematics in three dimensions. However it could be shown, that the three dimensional analysis of pole vaulting did not lead to improvements in energy calculations. Further improvements of technology allowed to measure the ground reaction forces in the planting box of the pole, synchronised with vetworks to gather the kinematical data. With this achievement it became possible to calculate the pole energy. The quantification of the athlete’s energy and the pole energy at the same time allowed identifying the actual energy exchange between athlete and pole. It could be shown that the amount of energy transferred to the pole is bigger than the decrease of the athlete’s energy, which means this energy difference results from muscular work of the athlete during rockback. In the second phase the pole returns energy to the athlete and the athlete does muscular work to increase his potential energy. The role of the pole during the vault is to store a part of the kinetic energy from the athlete’s run up (as strain energy) and return it as potential energy of the athlete. The second important function of the pole is to allow the athlete to produce muscular work while energy is stored in the pole to increase the total energy potential.

**RECENT METHODOLOGICAL ADVANCEMENT IN RESEARCH OF NORDIC SKIING**

Linnamo, V., Seppälä, S., Kolehmainen, V., Vähäsköyri, P., Pelkonen, J., Komil, P.V.

University of Jyväskylä and Vuokatti Sports Institute, Finland

Cross-country (x-c) skiing and skijumping have been studied quite frequently with kinematic methods. Kinetic approaches are more difficult to apply in natural condition but add valuable information for understanding the mechanisms involved. Special emphasis has recently been put to develop kinetic research methods in Vuokatti Sports Institute in Finland. These methods include force-plate systems installed in Vuokatti Ski Tunnel and on two different size jumping hills and a special ski-tester device.

In x-c skiing ski and pole forces are recorded separately with four rows of platforms. In order to capture several consecutive steps the system needs to be rather long. Therefore, a 20 m long system consisting of four rows of 1 m long individual plates recording the forces in two directions (Fx, Fy) was constructed and installed in the tunnel. This allows measurements of different slope conditions of diagonal x-c skiing all year round with controlled snow, temperature and humidity conditions. The two middle rows (for skis) are covered with snow similarly to the actual ski track. The metal surfaces of the outer two rows for the poles are covered with the glued tarter type material, the surface of which is on the same level as the two middle rows.

The effects of waxing and ski properties can, however, be difficult to estimate accurately as the force production even in experienced skier may vary considerably. In order to allow accurate measurements in laboratory conditions a ski tester that simulates the force production of natural skiing was developed. 13.7 m long tester using a 7.5 kW motor attached to a linear motor unit is equipped with pneumatic cylinder and 6 pieces of 1 m long force plates. A ski is attached to the cylinder and pressure against the force plates and the velocity of the ski can be adjusted.

For skijumping research, the force platform system should cover the entire take off including most of the run curve of the jumping hill. Consequently for a 90 m jumping hill the force platform must cover the last 15 m of the take off area and for 30 m hill the last 12 meters. In skijumping the two rows of similar construction as in x-c skiing are mounted permanently for two different size jumping hills (30 and 90 m) in Vuokatti.

The constructed systems are currently used for several research projects and combined with simultaneous multichannel EMG recordings and 3D kinematics. The platform of x-c skiing is utilized to understand in more detail the distribution of force production between legs and arms when the conditions of slope, speed, waxing, skis, poles, and snow are varied in a controlled manner. Ski tester has been tested to used to examine the effects of different waxing conditions on gliding properties and force production. In skijumping the force production measurements have been combined with accelerometer data and video analysis.

**THE INFLUENCE OF SUSTAINED SUB-MAXIMAL SKIING ON THE FREQUENCY AND INTENSITY CONTENT OF THE EMG SIGNAL**

Kroell, J., Wakeling, JM, Seifert, J., Birkbauer, J., Müller, E.

Christian Doppler Laboratory Biomechanics in Skiing, Austria

Quantifying fatigue processes in alpine skiing could be helpful in improving comfort, enjoyment and safety issues. It has been shown, that muscle activity changes during fatiguing exercises to exhaustion. Due to the fact that these changes can be observed in amplitudes / intensities and frequency contents of a signal, a method covering both aspects is essential. As with other dynamic exercises, the intensity analysis in time-frequency space of EMG signals by wavelets is a powerful analytical tool in alpine skiing (Kroell 2007). The purpose of this study was to investigate the influence of a sub-maximal skiing session on EMG frequency and intensity content of rectus femoris (RF) by the use of wavelets. Seven female subjects performed 24 runs on a slope with 300m elevation. Knee angle and EMG of RF right leg was measured during runs 2, 3 and 4 [PRE, 23+24=POST, 23=POST1, 24=POST2]. Knee angle and raw EMG were used to determine the start and end of each double turn (1st turn right leg = inside leg (IL); 2nd turn right leg= outside leg (OL)). The EMG signal of each run was resolved with a wavelet transformation into intensities for each point in time (10 centre frequencies between 19.3 and 395.4 Hz, von Tscharner 2000). ‘Double turns from the last segment of each run and each subject were used to calculate a representative turn. For descriptive analyses, intensity spectra were calculated for ten evenly spaced windows of each double turn. 3D intensity plots were then created. For statistical analyses, intensity spectra were calculated for IL and OL. A 1-way ANOVA with RM was used to analyze mean intensity and frequency for IL and OL.

A downward shift in mean frequency was observed for IL (82.1Hz/79.4Hz, 4Hz, p eta2=0.26, p=0.049) and OL (71.3Hz/68.3Hz, p eta2=0.50, p=0.049) between PRE and POST. Higher intensity values for IL (+15%, p eta2=0.10, p=0.439) and OL (+22%, p eta2=0.16, p=0.034) were observed for POST compared to PRE. However the treatment effect is clearly lower compared to the frequencies. The change between PRE and POST is larger than the change between POST1 and POST2 for the frequencies in IL (eta2=0.41, p<0.01) and OL (p eta2=0.53, p<0.01). The changes in intensity were not different for PRE vs. POST and POST1 vs. POST2 for IL (p eta2=0.03, p>0.99) and OL (p eta2=0.01, p>0.04).

Previously, alpine skiing researchers extracted only intensity and timing data from EMG. Our data demonstrate that the quantification of sub-maximal fatigue by intensity alone does not identify signal changes. This may be due to the high variability caused by the complex movements in alpine skiing (from turn to turn and from run to run) compared to e.g. isometric tasks. However frequency changes can be explained by the sub-maximal skiing treatment (run3 to run22). It is recommended that the focus be on frequency more than intensity in the description on muscular fatigue during alpine skiing.
In successful athletic performance. Although sports prowess (an important component of dancing) is undoubtedly defined by a constellation of trait and state sensorimotor communication, courtship, and spiritual facets of the dancing phenotype rather than other aspects of this complex phenotype, such as human religious and spiritual experiences. We therefore hypothesize that the association between AVPR1a and SLC6A4 reflects the social vertebrates and, more recently, in humans. Additionally, serotonergic neurotransmission in some human studies appears to mediate individual differences, and new common obesity susceptibility variants in unexpected genes have been identified. Last year, GWA resulted in the first major success in the field of obesity genetics with the discovery of FTO (fat mass and obesity-associated gene) as an obesity susceptibility gene. The studies identified independently a cluster of common genetic variants in the first intron of FTO showing consistent and highly significant association with BMI and severe early-onset obesity. This association has been unequivocally replicated in many populations of European descent. Individuals carrying 2 risk alleles weigh 3-4 kg more and have a 1.67 fold increased risk of obesity than those without risk alleles. Physiological experiments are being carried out to improve our understanding of the role of FTO in the development of obesity. Currently, the major challenge is to find more obesity-susceptibility variants using GWA. This will require large-scale data integration to obtain the power needed to identify common variants with likely modest effects. Therefore, as part of the GIANT (Genetic Investigation of Anthropometric Traits) consortium, we combined GWA data of 7 populations, including more than 16,000 individuals. The strongest association, seen in other studies, was mapped 18kb downstream of MC4R, a well-known gene causing monogenic forms of severe childhood obesity. This finding was confirmed in more than 60,000 adults and 6,000 children. Each risk allele is associated with a 0.22 kg.m-2 increase in BMI and a 12% increase in odds of obesity. Extended analyses within GIANT are ongoing, including more than 32,000 individuals, and new common obesity susceptibility variants in unanticipated genes have been identified. This presentation will review the latest findings in the obesity genetics field and will also highlight the promise and difficulties of the GWA approach.

GENES, PERSONALITY AND SPORT PARTICIPANTS

Ebstein, R., Bachner-Melman, R., Granot, R., Constantini, N., Salomon, I., Lerer, E. Laibe, E. Hebrew University, Israel

Dancing, integrally related to music and sport, likely has its origins close to the birth of Homo sapiens. The authors hypothesized that there are differences in aptitude, propensity, and need for dancing that may be based on differences in common genetic polymorphisms. Identifying such differences may lead to an understanding of the neurobiological basis of dancing. Our research group has been investigating the role of two nonapeptides, vasopressin and oxytocin, in human social behaviors including music and dancing. Our first study focused on comparing 85 current performing dancers, 91 competitive athletes and a group of 872 nondancers/nonathletes. We used a robust family-based analysis and genotyped all groups of subjects for the arginine vasopressin 1a receptor (AVPVA1 promoter repeats (RS1 and RS3) and the serotonin transporter (SLC6A4) promoter-region polymorphism (HTTLPR). Dancers scored higher on the Tellegen Absorption Scale, a questionnaire that correlates positively with spirituality and altered states of consciousness, as well as the Reward Dependence factor in Cloninger’s Tridimensional Personality Questionnaire, a measure of need for social contact and openness to communication. Highly significant differences in AVPVA1 haplotype frequencies (RS1 and RS3), especially when conditional on both SLC6A4 polymorphisms (HTTLPR and VNTR), were observed between dancers and athletes using the UNPHASED program package. Similar results were obtained when dancers were compared to nondancers/nonathletes. These results were confirmed using a robust family-based test. Association was also observed between Tellegen Absorption Scale scores and AVPVA1, and AVPVR1a conditional on SLC6A4. Similarly, significant association was observed between Tridimensional Personality Questionnaire Reward Dependence scores and AVPVR1a. Two-locus analysis (RS1 and RS3 conditional on HTTLPR and VNTR) was highly significant. Promoter repeat regions in the AVPVA1 gene have been robustly demonstrated to play a role in molding a range of social behaviors in many vertebrates and, more recently, in humans. Additionally, serotonergic neurotransmission in some human studies appears to mediate human religious and spiritual experiences. We therefore hypothesize that the association between AVPVA1 and SLC6A4 reflects the social communication, courtship, and spiritual facets of the dancing phenotype rather than other aspects of this complex phenotype, such as sensorimotor integration.

Although sports prowess (an important component of dancing) is undoubtedly defined by a constellation of trait and state sensorimotor processes, it should be considered that psychological factors that are also partially due to genetic predisposition, also play a crucial role in successful athletic performance.

GENETIC PREDISPOSITION FOR ELITE STRENGTH PERFORMANCE: WHAT DO(N’T) WE KNOW?

Thomis, M.

Katholieke Universiteit Leuven, Faculty of Kinesiology and Rehabilitation Sciences, Belgium

The maintenance of a high muscular fitness, both in muscle mass and strength, is positively related to bone health, functionality in daily life as well as an important factor in the control of insulin sensitivity. On the opposite, it is inversely related to falls and fractures, morbidity and mortality. In elite athlete performance, sports-specific strength characteristics (high isometric strength, high-velocity or power output, and muscular endurance) are one of many major contributors to final performance. Genetic epidemiologic studies have estimated the contribution of genetic factors to the interindividual variability in muscular strength components of non-athlete populations to be moderate to high (h²=31-95%). Multivariate studies in twins investigated a ‘strength generality’ versus ‘specificity’ hypothesis, to determine...
whether different strength phenotypes are determined by similar underlying genetic factors, or if they are largely strength-type specific. Within the ‘measured-genotype’ approaches, several research designs can be used to test the association of specific gene variants to observed variability in strength. This presentation will give an overview of candidate gene studies, linkage and fine-mapping studies and more functional genetics approaches that are applied in an attempt to detect ‘predisposing’ genes for high muscle performance. Results will be shown of genome-wide and myostatin pathway-based linkage studies for muscular strength phenotypes within the Leuven Genes for Muscular Strength Study. Focus will be given on identification of Quantitative Trait Loci using a genome-wide SNP-based multipoint linkage analysis, based on a 6008 SNP-panel Illumina Linkage IVb Panel for torque-length, torque-velocity and resistance to fatigue characteristics of knee musculature. Within linkage regions on chromosome 12, stepwise fine-mapping procedures have been worked out, that identified several candidate genes, for which variability in expressed mRNA levels for specific SNPs are now studied. As an example of candidate gene studies, an overview of studies of the ACTN3 gene with a high frequent stop codon polymorphism (R577X) will be presented. Both international studies, results from an animal knock out model and functional variant-effect studies within our laboratory will be presented. Finally an overview of other candidate genes and association studies related to muscular strength performance is given.

Invited symposia (IS)

IS-PM05 Exercise and the brain: clinical implications

EXERCISE AND NEUROTRANSMISSION: ARE THERE CLINICAL APPLICATIONS

Meeusen, R.

Vrije Universiteit Brussel, Belgium

Exercise can be a powerful tool in the rehabilitation of injured athletes, cardiac patients, and might have a profound effect on neurological diseases. There have been a number of studies that examined the exercise effect on a wide variety of pathological situations, and it seems that exercise works, although there is a general need for controlled trials.

Recently there has been more interest in the effects of exercise on brain processes. These new experiments arise mostly from animal studies where the basic knowledge on possible underlying physiological mechanisms are explored. From these animal studies it is known that exercise might be a ‘natural’ antidepressant, and that some neurotransmitters are influenced by regular exercise. Training will induce other neurochemical reactions, that might explain possible underlying neurophysiological arguments for the use of training in degenerative neurological diseases such as Parkinson’s disease and Alzheimer disease.

When exploring the possibilities for the use of exercise, there is now new striking evidence that an ‘enriched environment’ will lead to neurogenesis, meaning that new brain cells are formed when an animal is given the opportunity to explore new situations.

Extensive research on humans suggests that exercise could have benefits for overall health and cognitive function, particular in later life. Most recent studies have been directed towards understanding the neurobiological bases of these benefits. It is now clear that voluntary exercise can increase levels of brain-derived neurotrophic factor (BDNF) and other growth factors, stimulate neurogenesis, increase resistance to brain insult and improve learning and mental performance.

We will present recent evidence to illustrate these new frontiers of exercise in the treatment of several neurological disorders.

THE EFFECTS OF EXERCISE ON REDOX SYSTEM AND BRAIN FUNCTION

Radak, Z.

Semmelweis University, Hungary

Reactive oxygen species (ROS) are continuously generated during aerobic metabolism. Certain levels of ROS, which could be dependent on the type of cell, cell age, history of ROS exposure, etc., could facilitate specific cell functions. Indeed, ROS stimulate a number of stress responses and activate gene expression for a wide range of proteins. It is well known that increased levels of ROS are involved in the aging process and the pathogenesis of a number of neurodegenerative diseases. Because of the enhanced sensitivity of CNS to ROS, it is especially important to maintain the normal redox state in different types of neuro cells. In the last decade it became clear that regular exercise beneficially affects brain function as well, and can play an important preventive and therapeutic role in stroke, Alzheimer, and Parkinson diseases. The effects of exercise appear to be very complex and could include neurogenesis via neurotrophic factors, increased capillarization, decreased oxidative damage, and increased proteolytic degradation by proteasome and neprilysin. Data from our and other laboratories indicate that exercise-induced modulation of ROS levels plays a role in the protein content and expression of brain-derived neurotrophic factor (BDNF), tyrosine receptor kinase B (TrkB), and CREB, resulting in better function and increased neurogenesis. The enhanced activities of proteasome and neprilysin result in decreased accumulation of carbonyls and amyloid beta-proteins, as well as improved memory. It appears that exercise-induced modulation of the redox state is an important means by which exercise benefits brain function, increases the resistance against oxidative stress, and facilitates recovery from oxidative stress.

EXERCISE: PSYCHOSOCIAL IMPLICATIONS AND CLINICAL APPLICATIONS

Lemmyre, P. N.

Norwegian School of Sport Sciences, Norway

Over the past decade a myriad of studies has shown that physical activity is beneficial to brain health and performance in human populations, and that exercise participation is linked to higher cognitive functioning. Research in the sport domain has been predominantly aimed at investigating the role of the brain in optimizing performance. In the physical activity domain, research seeks to better understand important health and well-being issues such as perceived exertion and emotional benefits related to exercise participation, the influence of physical and mental fitness on the response and resilience to stress, as well as its role on cognitive performance related to learning and problem-solving.

Recent research efforts using multidimensional perspectives have attempted to better understand the role of exercise on well-being indices as well as its effect on a wide range of disorders. Recently an important line of research has focused on the effects of exercise on brain processes and how in return these brain processes influence physical activity outcomes. Based on these findings, it is suggested that physical activity represents an essential context for the development and maintenance of high levels of brain functioning, plasticity.
and health throughout a lifetime. Thus, it becomes a vital endeavour to better understand how these variables influence initiation and adherence to physical activity behaviour. While the expression of positive affect and high cognitive functioning are important indices reflecting positive exercise outcome, it is also clear that it transcends the physiological gains associated with physical activity. The cognitive appraisal of perceived changes associated with physical activity participation represents a potent determinant of the motivation necessary to exercise adherence. In order to better understand the role of physical activity and exercise to promote and maintain healthy brain functioning, we will present recent evidence illustrating the psychosocial determinants and outcomes associated with exercise and physical activity and exercise participation.

**TRAINING WITH LOW MUSCLE GLYCOGEN INCREASES FAT OXIDATION DURING EXERCISE**

Hulston, C., Venables, M., Mann, C., Philp, A., Baar, K., Jeukendrup, A.
University of Birmingham, United Kingdom

Introduction: Training adaptations are thought to be generated by elevated gene transcription and protein synthesis after repeated exercise bouts. These responses may be exaggerated when endurance exercise is performed with low muscle glycogen. Hansen et al. (1) reported increased exercise capacity after 10 weeks training with low glycogen. In this study the amount of work performed was the same in high and low glycogen conditions, even though higher glycogen would normally allow for exercise at higher intensities. As a result, the practical implications of the Hansen study are unclear. Therefore, the purpose of the present study was to determine the effect of muscle glycogen content on training adaptations when cyclists train at a self-selected intensity.

Methods: Fourteen male cyclists (pair-matched for VO2max and power output) were assigned to high (HIGH) or low (LOW) glycogen training groups. Subjects trained for 3-weeks, completing 3 aerobic (90 min at 70% VO2max) and 3 high intensity training (HIT) sessions (8 x 5 min interspersed with 1 min recovery) each week. Glycogen content was altered by the length of recovery between training sessions. HIGH trained once daily whereas LOW trained twice every second day. A short (1 h) recovery period in LOW meant glycogen content would be reduced at the beginning of every second bout. Self-selected power output during HIT was used as a measure of training intensity. Biopsies were taken from the V. Lateralis pre and post training to determine adaptations in skeletal muscle. Subjects performed a 1 h steady-state (SS) cycle at 70% VO2max and 1 h time trial (TT) to determine changes in substrate metabolism and performance.

Results: Power output during HIT was 323±10 W in HIGH and 297±7 W in LOW (P<0.05). TT performance was improved by a similar extent in both groups (10%). TT time decreased from 62.10±1.49 min pre-training to 56.37±1.17 min post-training in HIGH (P<0.05), whereas in LOW TT time decreased from 61.90±1.12 min pre-training to 56.12±1.22 min post-training (P<0.05). Fat oxidation during SS increased by 27% from 0.52±0.04 g/min (pre-training) to 0.67±0.04 g/min (post-training) in LOW (P<0.05). Fat oxidation tended to increase after training in HIGH (0.44±0.04 g/min to 0.48±0.01 g/min) but this did not reach statistical significance. Beta-HAD protein content increased by 38% after training in LOW (P<0.05) but decreased by 21% after training in HIGH (P<0.05). GLUT4 protein content was increased by 55% after training in HIGH (P<0.05) but was unaffected by training in LOW.

Conclusion: Training with low muscle glycogen increased resting beta-HAD protein content and increased fat oxidation during exercise. However, improvements in time trial cycling performance were similar in both groups.

**RECOVERY RESPONSES IN IRONMAN TRIATHLETES**

Neubauer, O., König, D., Wagner, KH.
1) University of Vienna, Austria, 2) Freiburg University Hospital, Germany, Austria

Background: Finding an appropriate balance between training, competition and recovery is an essential challenge for competitive endurance athletes in order to maintain a high level of performance and to minimise potential adverse consequences including an increased risk of infection and/or overreaching/overtraining. An acute bout of ultra-endurance exercise, such as an Ironman triathlon, induces muscle damage and a systemic inflammatory response that is associated with a transient immune dysfunction. However, information on the alterations of these responses beyond 1 day post-race is limited.

Purpose: The present study aimed to examine indices of muscle damage, immuno-endocrine and systemic inflammation parameters to quantify their magnitude and to verify the resolution of recovery following an Ironman triathlon in a large cohort of athletes.

Methods: Blood samples were taken from 42 well-trained male triathletes (mean±SD: age 35±3.7 yr, height: 180±6.5 cm, weight: 75±1.4 kg, cycling VO2 peak: 56±6±6.2 ml kg⁻¹ min⁻¹) 2 d before an Ironman triathlon, then immediately post-race, and 1, 5, and 19 d later. Blood was analysed for haematological parameters, plasma values of cortisol, testosterone, creatine kinase (CK) activity, myoglobin, polymorphonuclear (PMN) elastase, myeloperoxidase (MPO), interleukin (II)-6, IL-10 and high-sensitive C-reactive protein (hs-CRP). The athletes documented their training in the six months prior to the Ironman and thereafter until the end of the study, and performed recovery training that was of moderate intensity and duration post-race.

Results: Immediately post-race there were significant (P<0.001) increases in total leucocytes, granulocytes, cortisol, CK, myoglobin, PMN elastase, MPO, IL-6, IL-10 and hs-CRP, while lymphocytes, testosterone and testosterone-cortisol (T/C) ratio significantly (P<0.001) decreased. One d post-race these alterations persisted (P<0.001, P<0.01 for IL-10), with the exception of cortisol which decreased to below pre-race values (P=0.013) and T/C ratio which recovered. Despite a decline thereafter, CK activity, myoglobin, IL-6, IL-10 and hs-CRP remained significantly (P<0.001, P<0.05 for IL-10) elevated 5 d post-race. Moreover, several relationships between leucocyte dynamics, cortisol and muscle damage, cytokines and hs-CRP were observed.

Conclusions: An important finding of the current study was that although the pronounced initial systemic inflammatory response induced by an Ironman triathlon subsided rapidly, a low-grade systemic inflammatory response was sustained until at least 5 d post-race. The prolonged moderate, but significant elevation of markers of muscle damage and inflammation might indicate incomplete muscle recov-
LIVER, MUSCLE AND PLASMA ATP LEVELS IN RESPONSE TO A TREADMILL EXERCISE IN RAT AT REST: ATP BIOLUMINESCENCE ASSAY

Barmaki, S., Ghanbari-Niazi, A., Farshidi, Z., Ziaee, N., Fallah, S., Hosseinkhani, S.
Tarbiat Modares University and Mazandaran University, Tehran and Boulsar, Mazandaran – Iran, Iran

Introduction: the intracellular of ATP has been recognized as an energy source of mechanical works and several anabolic reactions. Cells have complex mechanisms for synthesizing ATP and maintaining or rapidly restoring the intracellular level, and one might therefore expect that release of ATP to the extracellular milieu would rarely occur. Nonetheless, extracellular ATP at low micro molar concentrations can influence many biological processes including platelet aggregation, vascular tone, neurotransmission |peripheral and central, cardiac function and muscle contraction. The effects of physical exercise at different form on skeletal muscle ATP concentration well documented. However, the effects of treadmill exercise training at moderate to high intensity on plasma and liver ATP levels is lacking or very less and conflicting data provided after acute exercise. The purpose of this study was to investigate the effects of 10 weeks of a treadmill exercise (60 min, 28 m/min, 0% grade) program on plasma, liver and skeletal muscle ATP contents in wild type male rats.

Methods: forty male Wistar rats (17-18 weeks old, and weighing 200-220g) used for this study and divided into four, fed-control, fed-exercise, fast-control, and fast-exercise. Animals were sacrificed 24 hours after the last session of exercise, the blood and tissue samples were collected. ATP was measured by using an enzymatic luciferine-luciferase method. Normal distribution of dependent variables was documented by Kolomogorov-Smirnoff test. The data were analyzed by ANOVA univariate and one way ANOVA. The level of statistical significance was set at P<0.05. Results: the data indicate that the level of liver ATP was significantly higher (P< 0.028) in trained group when compared with control group. A higher but non-significant plasma and muscle ATP concentrations were observed in trained rats. However, fasting lowered liver, plasma, and muscle ATP contents only in central rat trained-fasted rat. Discussion: the main finding of this study was a higher levels of liver ATP in trained rats following the treadmill training. Data also shows training attenuated a fasting-induced reduction of ATP in the liver, plasma, and muscle. A non-significant increase in plasma ATP levels might be related to the release of ATP from blood cells (erythrocyte and leukocytes) and a non-significant increase of muscle ATP content following treadmill exercise due to incomplete recovery of muscle glycogen content which acts as a source of ATP synthesis. This the first study which investigate the effects of 10 weeks of treadmill exercise training on plasma, liver and muscle ATP contents at rest. Conclusion: a higher resting liver ATP might be due to an exercise-induced increase in liver glycogen content and ATP uptake from plasma.

EFFECT OF ALLOPURINOL AND EXERCISE ON PROTEIN EXPRESSION IN RAT GASTROCNEMIUS AND SOLEUS MUSCLE

Veskoukis, A., Kontou, M., Kyparas, A., Nikolaidis, M., Samiotaki, M., Panayotou, G., Kourelas, D.
University of Thessaly, Greece

Allopurinol is an inhibitor of xanthine oxidase. Xanthine oxidase is a major contributor of free radicals during exercise. Previous studies from other laboratories have shown that free radicals are vital for physiological adaptations in exercise. To this end we studied the effect of allopurinol administration on protein expression in various rat muscles. Sixty adult male Wistar rats, 8 weeks old, weighing 220±10 g, means±SEMI, were randomly and equally divided into six groups as follows: a) DMSO-treated rats killed at 1.5 h after administration, b) DMOSO-treated rats exercised at 1.5 h after administration and killed immediately after exercise, c) DMOSO-treated rats exercised at 1.5 h after administration and killed 5 h after exercise, d) allopurinol-treated rats killed at 1.5 h after administration, e) allopurinol-treated rats killed at 2.5 h after administration, and b) allopurinol-treated rats killed at 7.5 after administration. Allopurinol was dissolved in dimethyl sulfoxide (DMSO) and administered intraperitoneally in a single dose of 50 mg/kg body weight at 1.5 h before the acute exercise protocol, as allopurinol peak plasma levels occur about 1.5 h after its administration. Exercise duration to exhaustion of DMOSO-treated rats lasted approximately 1 h. Allowing 7 days of acclimatization in the animal facility, animals were then familiarized to swimming for a period of five days before the actual swimming protocol. Rats of the exercising groups individually swam until exhaustion in deep water tanks at a water temperature of 33/36 °C. Gastrocnemius and soleus muscle samples were collected before, immediately after and 5 h after exercise in the respective time points after allopurinol administration. Tissue samples were homogenized using mortar and pestle followed by brief sonication treatment. Protein expression was assessed using sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). Preliminary results indicated differences in the expression of several proteins in the high molecular weight bands, whereas such differences were not observed in the soleus muscle. The protein bands detected to be differently expressed are currently analyzed using mass spectroscopy (LC/MS).

THE ASSOCIATIONS OF OBESITY AND EXERCISE PARTICIPATION WITH BLOOD LEVELS OF IL-6 AND TNF-945; IN KOREAN ADULT WOMEN

Kim, K., Hong, C., Kim, S., Gong, M., Park, J., Shin, Y., Byun, J., Jung, S.
Keimyung University, Korea, South

The aim of current study was to examine the associations of obesity and exercise participation with body composition, blood levels of IL-6 and TNF-945; in adult women. We studied 84 Korean adults women who volunteered in a health promotion program. Subjects were grouped according to fat as obese (30%, n=44) or non-obese (<25%, n=40), and were divided into 2 groups based upon spontaneous exercise participation, for using a cross-sectional approach. We measured anthropometric factors (BMI, percent body fat, WHR), and abdominal fat area by CT scanning, BP, blood levels of IL-6 and TNF-945; Associations among the variables were assessed by Pearson’s partial correlation and linear regression, controlling for age. Independent t-tests were used to assess differences between two groups. Significance was accepted at P<0.05. The ratio of muscular area to fat area in abdomen and thigh of obese group was significantly (P<0.05) lower than the non-obese group. The ratio of muscular area to fat area in thigh of exercise group was significantly (P<0.05) higher than the non-exercise group. Blood levels of IL-6 and TNF-945; of non-exercise group was significantly(p<0.05) higher than the exercise group. Blood levels of IL-6 and TNF-945; of non-exercise group was significantly(p<0.05) lower than the exercise group in obese and non-obese groups. Blood level of IL-6 was significantly(p<0.05) correlated with body fat, and TNF-945; level was significantly(p<0.05) correlated with abdominal and thigh fat area.
Obesity is strongly associated with sarcopenia, blood levels of IL-6 and TNF-945; in middle-aged women. Additionally, exercise participation may be protective against development of sarcopenia and increase of IL-6 and TNF-945;.

**ADIPOPHILIN DISTRIBUTION AND COLOCALISATION WITH INTRAMYOCYTOCELLULAR LIPIDS IN SKELETAL MUSCLE**

**Shaw, C., Wagenmakers, A.**

University of Birmingham, United Kingdom

Intramyocellular lipids (IMCL) are a dynamic cellular pool of stored fat that plays an important role in energy provision during prolonged moderate intensity exercise and regulates the availability of intracellular lipid signalling molecules. IMCL are stored as discrete lipid droplets which are surrounded by a phospholipid monolayer, embedded in which are a number of proteins. Adipophilin is the human orthologue of adipocyte differentiation-related protein and is the most abundant lipid droplet protein in skeletal muscle (1). Adipophilin appears to play a role in the regulation of lipolysis and fat oxidation by either protecting IMCL from basal lipolysis or in the interaction with hormone sensitive lipase (HSL) during exercise-mediated lipolysis (2). It has also been suggested that adipophilin might assist with the transport of fatty acids to the mitochondria.

The aim of this study was to investigate the subcellular distribution of adipophilin in human muscle fibres and to measure the colocalisation of adipophilin with IMCL. Muscle biopsies were snap frozen in liquid nitrogen-cooled isopentane and stored at -80°C. 5 µm cryosections were stained with anti-adipophilin in combination with anti-cytochrome C oxidase or the lipid dye oil red O. Images were acquired using laser scanning confocal microscopy and analysed using Image Pro Plus computer software.

Intracellular adipophilin was distributed throughout the muscle fibres and was approximately equal in size to the IMCL. In the present study 60% of the IMCL colocalised with adipophilin which is similar to the maximum reported reduction in IMCL content seen after prolonged endurance exercise (3). As HSL translocates to IMCL and adipophilin during muscle contraction and adrenaline stimulation in rat muscle in vitro, it is possible that the proportion of adipophilin-containing IMCL determines the lipolytic potential and therefore the degree of IMCL oxidation during exercise. There was also a large proportion (>50%) of adipophilin which did not colocalise with oil red O and the function of this adipophilin pool is unknown. Adipophilin however did not colocalise with mitochondria suggesting that it does not play a role in the channeling of liberated fatty acids to the mitochondria in the resting state.

**KNEE AND ANKLE ANGLES WHILE WALKING ON AN INCLINED SURFACE WITH AND WITHOUT HIKING POLES**

**Werner, I., Pfeifhofer, M.**

University of Innsbruck, Austria

To examine the effects of fatigue on balance and risks of stumbling while walking uphill or downhill, more information of gait characteristics is needed in undisturbed situations. Stride length increases when incline increases but when decline is increased, both longer and shorter strides have been reported (Leroux et al. 2002, McIntosh et al. 2006). Knee and ankle angles differ significantly between subjects and inclinations. Few studies have investigated walking with and without poles on inclined and declined surfaces. Therefore our pilot study focused on knee and ankle angles during uphill and downhill walking with and without hiking poles.

Five students (average age 25.6 years, four female, one male) took part in the study. They walked on a treadmill with a constant comfortable speed (4 or 5 km/h). The Lukotronic system was used to collect three dimensional positions of hip, knee, ankle and foot. The system employs active infrared markers with an accuracy of approximately 5mm. After 30 seconds of walking, data of 10 consecutive steps were gathered in 4 different conditions: incline of 20°, decline of 20°, with and without poles respectively. Knee and ankle angles were calculated by the limb positions in the sagittal plane. Means and SD of knee and ankle angles over all 10 steps were computed. Analyses of variance with the repetition factors slope (uphill or downhill) and poles (with or without poles) were calculated for knee angle and ankle angle separately.

Downhill walking resulted in lower knee angles than uphill walking. Knee angles showed a significant difference (p=0.025) between walking uphill with poles (131°) and walking downhill with poles (141°). Statistical analysis showed a trend (p=0.07) for the factor slope. The use of poles showed no effect, whereas interaction of slope and poles indicated a trend towards lower knee angles walking downhill. Walking without poles produced similar knee angles in both slope conditions. Mean ankle angles were less walking uphill, poles had no effect. Observing the range of motion, standard deviations of knee and ankle angles within each subject were greater walking downhill. This difference was strongly significant for ankle values. Poles and slope as well as their interaction showed no effect. Graphs of angle values against time revealed longer stride cycles when walking with poles. Treadmill velocity was constant, therefore we can assume that stride length increased when walking with poles both uphill and downhill.

**MODIFIED MUSCLE ACTIVATION PATTERNS IN RUNNING OVER STEPS OF DIFFERENT HEIGHT**

**Müller, R., Blickhan, R.**

Institute for Sports Sciences, Friedrich-Schiller-University Jena, Germany

Introduction: Humans run across changing surfaces with ease. They adjust their leg stiffness and angle of attack to accommodate changes in surface stiffness (Ferris et al. 1998) and surface roughness (Grimmer 2008). An upward step in the ground results in reduced leg stiffness and a flatter angle of attack (Blickhan et al. 2007). More precisely, the ankle joint angle as well as the ankle joint moment decreases with increasing step height, whereas the knee joint angle decreases but the knee joint moment remains unchanged (Grimmer
INFLUENCE OF PHYSICAL DEVELOPMENT ON SPRINT START DURING ADOLESCENCE

Aerenhouts, D., Muylaert, L., Hagman, F., Clarys, P., Delecluse, C., Van Gheluwe, B.
Vrije Universiteit Brussels, Belgium

Introduction
In the sprint disciplines of track and field, a good start is of considerable importance. Besides technical skills, also strength and power exertion on the start blocks affect start performance.

Aim
The aim of this study is to examine possible influences of physical development during adolescence on the sprint start.

Methods
According to Flemish Athletics League rankings, top 10 boys and girls of each sprint discipline were invited for voluntary participation. Both in 2006 and 2007, anthropometrical measurements were taken and total body skeletal muscle mass (SMM) was calculated (Poortmans et al., 2005). A sprint start was performed with instrumented start blocks enabling the recording of horizontal forces. A laser measured time and running velocity at 5m from the start line.

Results
Both in 2006 and 2007, 25 girls and 21 boys (age in 2006: 14.8 ± 1.5 and 14.4 ± 1.8 years respectively) were tested. Between the two test periods, height increased (p < .001) for both boys and girls (167.8 ± 6.6 vs. 168.9 ± 6.1 cm and 171.1 ± 11.7 vs. 174.9 ± 9.0 cm respectively). A greater increase for the boys (p < .01). Boys increased their SMM (p < .001: 23.1 ± 4.8 vs. 25.5 ± 4.3 kg) significantly more (p < .001) than girls (p < .01: 19.5 ± 3.1 vs. 20.3 ± 3.1 kg). Velocity when leaving the start blocks was significantly higher in 2007 than in 2006 for both boys and girls (p < .05). This change in velocity correlated with the change in sum of the left and right peak forces on the blocks (girls: r = .57, boys: r = .81, both p < .01). In boys only, the change in velocity correlated (p < .05) with the change of the corrected thigh girth (r = .43) and SMM (r = .47). Only in girls, elapsed time at 5m was less in 2007 (p < .05) which correlated with a higher impulse on the rear block (r = -.57, p < .01). Neither for girls or boys, running velocity at 5m was higher in 2007 than in 2006. In boys, a change in running velocity correlated positively with the increase of corrected calf girth (r = .61, p < .01) and SMM (r = .45, p < .05).

Discussion
Velocity when leaving the start blocks is highly affected by the ability to induce higher forces on the start blocks in both sexes. Muscular development directly influences this higher force development as well as a higher running velocity at 5m in boys and a faster time at 5m in girls. A higher gain in SMM for boys compared to girls at this age may explain the differences between the sexes. Despite a higher SMM, these athletes were not running faster at 5m in 2007 than in 2006. Sufficient specific training on sprint start skills and to create a passive transfer from strength gain is proposed.

MUSCLE RECRUITMENT PATTERN IN LOW-BACK MUSCLES DURING CYCLING SPRINTS

Arpinar-Avsar, P., Kosar, N., Soylu, A.
Middle East Technical University, Turkey

Different causative factors have been shown to be responsible for the low back pain suffered by many cyclists. However, the aetiology of the pain has not been well explained. Due to the nature of bipedal motion, we hypothesized that sudden increases in movement velocity during cycling sprints would affect the muscle activity pattern in low back muscles and might result in bilateral asymmetrical periodic load occurred around the lumbar region which triggers the incidence of further low back pain episodes. Therefore, the purpose of this study is to investigate muscle recruitment pattern in low-back muscles during 30-second cycling sprints. 7 healthy active male subject (age: 18-21, weight: 70 ± 6.04, height: 178 ± 2.73) were underwent 30-second Wingate test on Monark bicycle ergometer (894E) against the resistance of 7.5% g/kg of body mass. Following 5-minutes of warm-up, Surface EMG was recorded bilaterally from low back extensor and stabilizer muscles: Erector Spinae (lower part IES) and Multifidus (MF). Two photocells were mounted on the ergometer to collect synchronized time data as the pedal passes top and bottom dead center. Before the tests subjects performed maximal voluntary isometric back extension to obtain peak EMG activity to normalize the subsequent EMG data collected during the dynamic exertions. Raw EMG signals recorded during 30-second cycling sprint were amplified, filtered, sampled at 1000 Hz. Normalized data full-wave rectified and the root-mean-square (RMS) and average muscle activation of each muscles were computed for 5-second periods. Asymmetrical loading was observed in back muscle activation pattern during 30-second cycling sprints (p < 0.01). Average activation of low back extensor and key stabilizer muscle of the lumbar spine were higher in the left side (IES/MF). This finding could be explained by the difference in maximal and explosive force production capacity of the muscles at dominant and non dominant sides of the subject. Although, cycling...
cadence increased at the beginning of the sprint (2nd phase), both the muscle activation and the average peak power output decreased linearly. RMS values of each muscle EMG slightly increased at 5th phase probably due to the change of trunk position when bending forward and greater recruitment of fast switch fibres. In this preliminary study, the results revealed that 30 seconds of maximal cycling sprint against pre-determined load results in asymmetrical contraction pattern of low back muscles throughout the entire test which might be considered to aggravate unilateral spinal loading.

BIOMECHANICAL ANALYSIS OF MAXIMUM FOREHAND TOPSPIN STrokes in TABLE TENNIS DURING FATIGUE

Heller, M., Baca, A., Kornfeind, P.
University of Vienna, Austria

Table tennis is characterized with intermittent intervals of explosive (anaerobic) muscle activity. Even though professional players still need to have a high level of aerobic abilities. Only little is known about the players’ neuromuscular ability to perform sports specific tasks with high precision as well as maximum speed until exhaustion.

A standardized protocol has been developed where top players are monitored through kinematic, kinetic and surface electromyographic (sEMG) variables when performing a repetitive maximum forehand topspin movement, practicing with a table tennis robot, in such a dynamics and duration as to induce fatigue (Baca et al., 2007).

The aim of the present case study was to analyze changes in whole body kinematics, kinetics and sEMG signal behaviour of the stroke arm during such a fatiguing movement.

According to the protocol developed, a top level young Austrian player (right hander) underwent an intensive exercise consisting of 22 consecutive sequences of 12 strokes with maximum speed. 3D-kinematics (VICON), kinetics (Kistler) and electromyographic data (Delsys) from m. deltoideus anterior, m. deltoideus medialis, m. biceps brachii and m. pectoralis major were collected. From the raw data recorded characteristic parameters and time series of these parameters (integrated EMG (iEMG), median frequency (MDF); magnitudes of distances, velocities and accelerations; time instants of maximum/minimum values of these magnitudes) were calculated and analysed.

Major findings are as follows: the time-dependent variability of kinematics, kinetics and sEMG signals decreased over time, the initial increase of the mean values of the maximum magnitudes of the right finger velocity up to 15 m/s, this parameter gives indications on how the ball was hit, could also be observed in the iEMGs of the m. biceps brachii; the player was well able to hit a marked area on the table during the whole exercise. Contrary to expectations, muscular activity (iEMG, MDF) showed either almost no changes (m. pectoralis major), or a slight decrease (m. deltoideus anterior), or an increase followed by a slight decrease (m. biceps brachii) or a considerable decrease (m. deltoideus medialis).

The results suggest that even if there are partly decreased muscular activities from agonists, which are supposed to be a result of fatigue, a professional player is able to maintain the motor task at a relatively high level.

DEVELOPMENT OF A SYNCHRONIZED SYSTEM OF PIV AND MOTION ANALYSIS, AND ITS APPLICATION TO A FRONT CRAWL SWIMMER

Muramatsu, Y., Matsuuchi, K., Nomura, T., Sakakibara, J., Miwa, T.
University of Tsukuba, Japan

Schleihau evaluated a force exerted on a swimmer’s hand using a quasi-steady analysis. However, the flow field around a swimmer is extremely unsteady. To obtain a deep understanding on the generating mechanism of force in unsteady conditions, it is necessary to know the relationship between swimmer’s motion and the flow field around a swimmer. Particle Image Velocimetry (PIV) can visualize the unsteady flow field. In addition, a motion analysis system can analyze the unsteady motion of a swimmer quantitatively by Direct Linear Transformation (DLT). Yamada used these methods separately and concluded that the hand motion in swimming was closely related to the vortex generation. Our main aim was to construct a synchronized system of PIV and a motion analysis, and to apply it to a front crawl swimmer, in order to clarify the simultaneous relationship between swimmer’s hand motion and the vortex generation by hand.

In the traditional study, PIV and a motion analysis has been carried out under the quite different lighting conditions. To combine these methods, we illuminated a swimmer’s hand with the red lights, and separated the light by passing it through Laser Line Band Pass Filter and Red Band Pass Filter for a CCD camera (PIV) and for two synchronous high-speed cameras (a motion analysis), respectively. In addition, using a pulse generator we set all cameras to start at the same time and to capture images every 68 ms in PIV and every 4 ms in the motion analysis. The experiment was carried out at the flume installed in the Univ. of Tsukuba whose dimensions of the test section are 4.6 m in length, 2.0 m in width, and 1.5 m in depth. The flume has the ability of 2.5 m/s at the maximum velocity. The subject was a male with a competitive career of triathlon. The flow velocity was set to be 1.0 m/s. The measurement planes were located at the depths of 70, 64, 58 and 52 cm below the water surface. To evaluate quantitatively the orientation of hand, the palm trajectory, velocity and the angle of attack were derived from the coordinates calculated by a video motion analysis system Frame-DIAS based on DLT. In addition, the velocity and vorticity distributions were derived from the particle image data.

From the results obtained by the synchronized system, we derived the relationship between the temporal variation of the angle of attack of hand and that of the corresponding flow field when the motion was in the transition phase. It was confirmed that vortices were generated and then released from the hand in the phase.

STEP-UP SENIOR: A PHYSICAL ACTIVITY PROGRAM TO IMPROVE FUNCTIONALITY IN THE ELDERLY

Machado, M., Moreira, H., André, H., Santos-Rocha, R., Carnide, F., Veloso, A.
Faculty of Human Kinetics, Technical University of Lisbon, Portugal

We are living in the age of longevity. Population ageing represents a triumph of social development and public health. Ageing is now the norm rather than the exception, and we can exert crucial influence in increasing awareness and designing broad initiatives to highlight the opportunities brought to individuals and societies by living longer. Based on this premise some physical activity programs were developed, such as, the Step-Up Senior Exercise Program (1-4) that was designed to improve the quality of life and the participants’ fitness components. People are challenged to follow a routine, which involves stepping up and down on platforms of varying heights, at varying cadences, in order to achieve a sound workout. Three sessions per week were performed (60 minutes) subdivided into warm-up (12 minutes), cardiovascular (20 minutes, 60-79 %HRmax), strength (1-3 sets of 12-15 reps), flexibility & cool-down. The data from the 4 years follow-up assessed by the Senior Fitness Test - SFT (5) suggested that this program had a positive impact on the ageing delay by reducing the risk of making them prone to falling or other accident related injuries once the results of the 8-foot-up & go and chair stand tests are related to falls prevention (6). This was consistent to the kinetic results from walking tasks, which showed that after 2 years the participants produced Ground Reaction Force (GRF) patterns similar to youngsters during unobstructed walking (7). However, age significantly affects some force impulses during obstacle negotiation, highlighting the hypothesis that senior step exercise programs might improve gait stability in elderly. This positive effect is lessened in the case of more demanding walking tasks and this should be taken into account in the development of the program. We also find that the mechanical stress associated with the program seems to constitute a positive osteogenic stimulus and is a safe and healthy activity that may be included in the physical activity programs for the elderly. Even after six months, the 71 subjects have shown positive changes in body composition, experienced by the reduction of total and mainly central adiposity, directly related to cardiovascular risk (8). We firmly believe that increasing the adherence to this program we might counteract the effect of aging, contributing to a healthier, independent lifestyle, greatly improving the functional capacity and quality of life of this population.

REFERENCE SCORES FOR PHYSICAL FUNCTION IN ELDERLY

Pereira, C., Baptista, F.
University of Évora, Portugal

Evaluation of physical activity in elderly has been interpreted taking scores from people of the same age group and gender as reference. Purpose: This study intend to describe physical function in elderly using as reference scores from a young adult group of the same gender aged 20-29 yrs, the age range at which peak physical function is assumed to have occurred. Methods: Participants were 559 active community-residing elderly engaged in an exercise programme at least 2 sessions/week in the previous year (423 women aged 60-88 yrs. 69 ±5.8yrs and 136 men aged 60-87 yrs. 70 ±6.6yrs). 79 young adults (50 women, aged 20-28 yrs. 22.8±2.1yrs and 29 men, aged 21-26: 23.2±1.6yrs). Participants were separated into six age groups, namely: 20-29 yrs (Y), 60-64 yrs (A), 65-69 yrs (B), 70-74 yrs (C), 74-79 yrs (D) and 80 yrs (E), in both genders. Lower and upper body strength (LBS and UBS), lower and upper flexibility (LBF and UBF), agility (Ag), and aerobic endurance (AE) were evaluated by the Fullerton battery for functional fitness. All physical function attributes in elderly participants were expressed as T-scores [(elderly attribute score - mean of young adult attribute score)/standard deviation of young adult attribute score]. The T-score indicates how many standard deviations (SD) above or below the average value, the result in young adult attribute score is the norm rather than the exception, and we can exert crucial influence in increasing awareness and designing broad initiatives to highlight the opportunities brought to individuals and societies by living longer. Based on this premise some physical activity programs were developed, such as, the Step-Up Senior Exercise Program (1-4) that was designed to improve the quality of life and the participants’ fitness components. People are challenged to follow a routine, which involves stepping up and down on platforms of varying heights, at varying cadences, in order to achieve a sound workout. Three sessions per week were performed (60 minutes) subdivided into warm-up (12 minutes), cardiovascular (20 minutes, 60-79 %HRmax), strength (1-3 sets of 12-15 reps), flexibility & cool-down. The data from the 4 years follow-up assessed by the Senior Fitness Test - SFT (5) suggested that this program had a positive impact on the ageing delay by reducing the risk of making them prone to falling or other accident related injuries once the results of the 8-foot-up & go and chair stand tests are related to falls prevention (6). This was consistent to the kinetic results from walking tasks, which showed that after 2 years the participants produced Ground Reaction Force (GRF) patterns similar to youngsters during unobstructed walking (7). However, age significantly affects some force impulses during obstacle negotiation, highlighting the hypothesis that senior step exercise programs might improve gait stability in elderly. This positive effect is lessened in the case of more demanding walking tasks and this should be taken into account in the development of the program. We also find that the mechanical stress associated with the program seems to constitute a positive osteogenic stimulus and is a safe and healthy activity that may be included in the physical activity programs for the elderly. Even after six months, the 71 subjects have shown positive changes in body composition, experienced by the reduction of total and mainly central adiposity, directly related to cardiovascular risk (8). We firmly believe that increasing the adherence to this program we might counteract the effect of aging, contributing to a healthier, independent lifestyle, greatly improving the functional capacity and quality of life of this population.

HABITUAL PHYSICAL ACTIVITY AND SELF-PERCEIVED FUNCTIONAL FITNESS AND SELF-SUFFICIENCY FITNESS AMONG MEN OVER 60 YEARS OLD

Oinski, W., Szeklicki, R.
University School of Physical Education in Poznan, Poland

Participation in appropriate physical activity by elderly people is usually positively related with health and functional fitness. Much less is known about the role of habitual physical activity (HPA) and potential benefits resulting from this type of activity are often omitted and underestimated.

OP-HF03 Health and Fitness 3 - Elderly
The aim of the study was to assess the relations between HPA and self-perceived functional fitness and self-sufficiency fitness among men over 60 years of age. The participants of the study were 137 men (60-88 years, average=72.6±5.8) living in Poznan (city in Poland, about 700 thousand inhabitants). The participants were retired, free from severe illness, who didn’t participate in any organized programme of physical activity. For measuring HPA the Coltrac accelerometer (Muscle Dynamics Fitness Network, USA) was used. HPA was expressed as a value of weekly energy expenditure related to physical activity (PA-EE). The value of PA-EE calculated per kg of weight (PA-EE/kg) was also used. Self-perceived functional fitness and self-sufficiency fitness were estimated using the questionnaire, fulfilled during the individual interview. By choosing one answer, participants estimated the level of difficulty in performing of daily activities related to functional fitness (seven types of activities) and self-sufficiency fitness (ten types of activities). Each one from three possible answers had its own point score: 1 I can’t make it by one-self, 2 I can make it with troubles, 3 I can make it without any troubles. The sum of points was used, as the expression of functional fitness and self-sufficiency fitness level. The Spearman correlation was used in statistical analysis. Significant and positive relations of self-perceived functional fitness with PA-EE (r=0.378; p<0.001) and PA-EE/kg (r=0.439, p<0.001) were noticed. Also the self-sufficiency fitness level was positively related with PA-EE (r=0.510, p<0.001) and PA-EE/kg (r=0.547, p<0.001). Obtained results allow the conclusion, that HPA has the significant relationships with maintaining functional independence and optimal quality of life of elderly men. However, the interpretation of confirmed phenomenon has to be mutual. Undoubtedly, higher levels of functional fitness and self-sufficiency fitness are favourable in undertaking wider range of activities related not only to HPA. The precise estimation of cause-effect relation is very difficult to explain.

**BODY WEIGHT UNLOADING: AN ALTERNATIVE FORM OF EXERCISE FOR OVERWEIGHT POSTMENOPAUSAL WOMEN**

Giannopoulou, I., Macaluso, A., Sacchetti, M., Panarelli, M., Watson, D., Wei Liang, Q., Nimmo, M. 1 University of Strathclyde, Scotland, 2 Istituto Universitario di Scienze Motorie, Italy, 3 North Glasgow NHS Trust, Scotland, 4 Loughborough University, United Kingdom

Exercise, even in the form of a single exercise session, can produce significant improvements in the glucose and lipid metabolism of overweight postmenopausal women. However, despite their benefits, weight bearing exercises such as walking can also increase the risk for injuries especially in overweight individuals that have a high prevalence of musculoskeletal problems. This study proposes using an alternative form of exercise that unloads a percentage of body weight (BWU) while exercising on the treadmill and thus potentially reduces the risk for injury. Hence, the purpose of this study was to investigate and compare the acute effects of treadmill walking with and without BWU on substrate utilisation and glucose turnover in healthy overweight postmenopausal women.

Six healthy, overweight postmenopausal women (age: 58±7 years; body mass: 66.4±4.0 kg; body mass index: 25.5±2.1 kg/m²; mean±SD) volunteered to participate in the study. All subjects participated in 3 exercise sessions: an incremental exercise test to fatigue to identify the ventilatory threshold (VT) of each subject, and two experimental exercise trials with and without BWU in a lattice square design. Each experimental trial consisted of 120 minutes of resting measurements followed by 60 minutes of exercise on the treadmill at 70% of VT with and without BWU, and 60 minutes recovery. During the duration of the experimental trials, continuous infusion of [6,6-2H2]glucose was performed, and at specific time points of the trials pulmonary gas exchange samples and blood plasma samples were collected. No significant differences were found in glucose turnover and utilisation during exercise between the experimental trials. Significant increases (+6.1±0.6 umol/kg/min, P<0.05) in glucose rate of appearance (Ra) and rate of disappearance (Rd) were found during exercise, while blood glucose was significantly reduced (-0.35±0.01 mmol/l, P<0.05) after exercise in both trials. Plasma glycerol concentration, an index of lipolysis, was significantly increased (+0.179±0.161 mmol/l, P<0.05) during exercise in both trials with no significant differences found between them. Finally, fat and carbohydrate oxidation rates did not differ between trials, and both increased as a result of exercise. In conclusion, exercising on the treadmill with BWU is an effective alternative form of exercise to regular walking in healthy overweight postmenopausal women, as it produces similar changes and benefits on the glucose and lipid metabolism of this population.

**SPORTING AND LEISURE TIME ACTIVITIES OF OLDER PEOPLE**

Hinrichs, T., Trampisch, U., Endres, H., Burghaus, I., Kloaaßen-Nielke, R., Lungenhausen, M., Platen, P. Ruhr-University Bochum, Germany

Objective: Although the benefits of physical activity for health and functioning are recognized to extend throughout life, data on physical activity habits of elderly people are scarce. The aims of this study were: 1. To perform a detailed analysis of the sporting and leisure time activities in a cohort of elderly people in Germany 2. To evaluate the association between general health and physical activity in this cohort.

Methods: In a monitored prospective cohort study (German epidemiological trial on ankle brachial index, getABI), 6880 unselected patients >= 65 years were followed up by 344 representative primary care physicians in Germany since November 2001. In the 5-year follow up, 2120 patients (median age 76, 70-94 years, 53.7 % women) of the cohort were interviewed in their level of physical activity (activity of moderate intensity for at least 30 minutes per session, 1: no activities or active for less than once per week, 2: active for 1-3 times per week, 3: active for > 3 times per week) and on their general health (1: excellent to 6: very poor). In a subgroup of 1376 patients (median age 76, 70-94 years, 54.7 % women), a detailed analysis of sporting and leisure time activities was performed.

Results. Of the 2109 (out of 2120) patients, who answered the questions on activity level and on general health in the 5-year follow up, 57 % reported a high activity level (level 3), 23 % an intermediate activity level (level 2) and 19.4 % reported to be inactive (level 1). Women and men did not differ significantly in their reported activity level. Activity level was associated to self-reported general health of the previous 4 weeks. The better the health status, the higher was the specified level of physical activity (Stuart’s Tau-c = -0.15, p < 0.001, e. g. 70.1 % of the 107 patients with an “excellent general health” were physically active for more than 3 times per week, whereas only 34.9 % of the 63 patients with a “poor general health” reached the same activity level. The detailed analysis of sporting and leisure time activities in the subgroup of 1376 patients showed that 74.7 % had taken an outdoor walk and 18.8 % had made a bicycle tour or ridden on a bicycle ergometer during the previous week. During the previous month, 24.8 % of patients had made gymnastics or strength train-
ing, 16.6% had swum, and 6.2% had bowled or danced. Every other sporting activity had been performed by less than 5% of patients during the previous month.

Conclusions: The level of physical activity is associated to self-reported general health in elderly people. Only a small percentage of elderly people do sporting activities other than walking, cycling, gymnastics, strength training, swimming, bowing or dancing.

The study has been conducted within the research cooperation PRISCUS (Prerequisites for a new health care model for elderly people with multimorbidity) which is funded by the German Federal Ministry of Education and Research 01ET07

RELATIONSHIPS BETWEEN HABITUAL PHYSICAL ACTIVITY AND MORPHOLOGICAL AND METABOLICAL FACTORS OF HEALTH-RELATED FITNESS AMONG ELDERLY MEN

Szeklicki, R., Osinski, W.
University School of Physical Education in Poznan, Poland

Health benefits resulting from undertaking appropriate physical activity by elderly people are indisputable nowadays. However, the results of studies on the relations between habitual physical activity (HPA) and health are not clear and potential benefits resulting from this type of activity are often omitted and underestimated.

The aim of the study was to assess the relations between HPA and morphological and metabolical factors of health-related fitness (HRF) among men over 60 years of age.

The participants of the study were 137 men (60-88 years, average=72.6±5.8) living in Poznan (city in Poland, about 700 thousand inhabitants). The participants were retired, free from severe illness, who didn’t participate in any organized programme of physical activity.

For measuring HPA the Caltrac accelerometer (Muscle Dynamics Fitness Network, USA) was used. HPA was expressed as a value of weekly energy expenditure related to physical activity (PA-EE). The value of PA-EE calculated per kg of weight (PA-EE/kg) was also used. In terms of somatic characteristics body height, weight, waist and hip circumferences, body composition (FM and FFM) and bone mineral density (BMD) were established. Body Mass Index (BMI) and the waist to hip ratio (WHR) were calculated. Selected metabolic factors were marked in blood plasma. The concentration of total cholesterol (TC), HDL-cholesterol, triglycerides (TG) and glucose (Glc) were marked. Also the level of LDL-cholesterol, TC/HDL and HDL/LDL indices were calculated.

In conclusion, the significant role of HPA in more beneficial distribution of fat tissue was proved, when there is a lack of direct relationships between HPA and other somatic characteristics or between HPA and metabolical components of HRF. These observations indicate that we should appreciate the significance of HPA for the health of elderly men. It was also showed the necessity of using the relative value of HPA, when expressed by energy expenditure, it must be calculated per kg of weight.

OP-PM07 Physiology 7 - Energetics

EFFECTS OF SHORT TERM HIGH-INTENSITY CYCLING EXERCISE ON LACTATE DISTRIBUTION IN RED BLOOD CELLS AND PLASMA

Wahl, P., Frese, S., Zinner, C., Lenzen, E., Suhr, F., de Marées, M., Mester, J., Bloch, W.
Institute of Training Science and Sport Informatics, Department of Molecular and Cellular Sport Medicine, 3German Research Centre of Elite Sport, Germany

Introduction

Several studies described the lactate distribution in blood under resting conditions and the effects of exercise on plasma and erythrocyte (RBC) lactate ([La]) concentrations. The ‘cell-to-cell lactate shuttle hypothesis’ is meanwhile an established theory but there is still limited knowledge about the (saturation) kinetics of lactate transport in different tissues and differently trained individuals. In this study we investigated a closed meshed time course of lactate distribution in plasma and erythrocytes after a maximal exercise test in elite cyclists.

Methods

12 healthy male cyclists participated in this study. Subjects performed a 30sec lasting maximal sprint test on a cycle ergometer. The cycle ergometer was adjusted to an isokinetic mode regulating the cadence to 120rpm. Subjects were instructed to perform the test in a sitting position on the ergometer. Blood samples were taken pre. Omin, 1min, ... 10min each minute after exercise to determine lactate concentrations in whole blood, plasma and erythrocytes. After the test subjects stayed in a resting position on a chair.

Results

Subjects reached a mean peak power (PP) of 976.1±101.5 Watt and a mean power (MP) 697.6±62.6 W. The mean ratio between RBC and plasma [La] under resting conditions was 0.54±0.04 [AU], showing a plasma [La] approximately twice as high as in RBC. The ratio between RBC and plasma [La] significantly decreased to 0.32±0.03 [AU] (40.7%) 0min past exercise, showing a faster relative/proportional increase in plasma [La] compared to RBC [La]. Afterwards [La] ratio started to increase again. After the 5th minute plasma lactate levels started to decrease while RBC lactate levels still increased. The plasma-to-RBC-concentration gradient shows that plasma lactate concentration increases faster up to 3min after exercise compared to RBC lactate levels. Between the third and fifth minute RBC lactate concentration increased faster than plasma lactate concentrations. After the fifth minute plasma lactate concentration started to decrease whereas RBC lactate levels still increased.

Discussion

The decrease in ratio is the consequence of a delayed lactate transport across RBC membrane and/or the consequence of a saturation of the transport systems. The fast congestion of lactate in plasma exceeds the transport capacity of the RBC membrane. But in this context
it should be considered that the total driving force for the (co-)transport of lactate and H+ by monocarboxylate transporters is composed of both the lactate and the proton gradients. Higher H+ concentrations in plasma increase the influx of lactate into RBC. Further investigations should measure lactate as well as H+ ions to determine flux in vivo.

PRESCRIBING EXERCISE INTENSITY BASED ON VO2MAX FAILS TO INDUCE PERIPHERAL ADAPTATIONS IN SOME PEOPLE

McPhee, J., Tomlinson, D., Williams, A., Jones, D.
Manchester Metropolitan University, United Kingdom

INTRODUCTION: The health benefits of endurance exercise include both cardiac and skeletal muscle adaptations, the latter conferring improved functional capacity, insulin sensitivity and lipid metabolism. The response of the muscle to endurance training is highly variable between people even when training at the same percentage VO2max (1). We hypothesised that part of the variable response may be due to the muscle receiving different training stimuli as a consequence of differences between people in the relationship between muscle size and cardiac output. METHODS: Before and after training (45 min, 3/wk, 6 wks at 70-80% VO2max). 55 previously untrained female participants had their two-leg cycling VO2max measured and maximal cardiac output (Qmax) estimated (2). Participants also completed one-leg cycling VO2peak tests and quadriceps muscle volume was determined by MRI in 30 participants. Participants were ranked by the ratio, expressed as a percentage, of their one-leg VO2peak compared to their two-leg VO2max (ratio-1:2). RESULTS: Before training, the mean ratio-1:2 was 76% (+/- 9 SD; range 58-96%). Two subgroups were selected; High (n = 7) being > 1 SD above and Low (n = 9) being > 1 SD below the mean ratio-1:2. Height, body mass, two-leg VO2max and Qmax did not differ between groups but one-leg VO2peak was 50% higher (2.37 +/- 0.22 Vs 1.58 +/- 0.39 L.min-1; p = 0.003) and quadriceps muscle volume 19% greater (1.47 +/- 0.14 Vs 1.24 +/- 0.17 L; p = 0.030) in the High than the Low group. The High and Low groups had similar moderate increases in VO2max and Qmax following training but the improvement in one-leg VO2peak for the low group was 29 +/- 20% (p = 0.001) with no significant increase for the High group. DISCUSSION: The ‘balance’ between cardiac capacity, as reflected by Qmax and quadriceps muscle size varied between these untrained females. Most of the variability was attributable to differences in quadriceps muscle volume. Since VO2max is mainly determined by cardiac output, when exercising at the same percentage VO2max, participants with relatively large muscles were working at a lower percentage of their muscle capacity compared to participants with smaller muscles. This may account, at least in part, for the greater muscle adaptations seen in the High group. CONCLUSION: Endurance cycle training carried out at a fixed percentage of VO2max provided an adequate stimulus for cardiac adaptations in all participants. However, individuals with relatively large muscles may need to exercise at a higher intensity in order to provide an adequate stimulus for muscle adaptations that are the basis for some of the health benefits of exercise.

EFFECT OF A SINGLE BOUT OF MODERATE-INTENSITY EXERCISE ON FAT OXIDATION KINETICS

Chenevière, X., Malatesta, D., Ebenegger, V., Borrani, F.
University of Lausanne, Switzerland

Introduction
During aerobic exercise, fuel substrate utilization depends largely on exercise intensity (3). Absolute fat oxidation rates increase from low to moderate exercise intensities and markedly decline at high intensities, which implies an exercise intensity (Fatmax) at which the rate of fat oxidation is maximal (WFO). In addition, muscle glycogen depletion induced by exercise duration results in an increase in fat oxidation during (5) and after exercise (2). Exercise intensity and duration appear therefore to play a predominant role in fat mobilization. The present study aimed to examine the effect of 1-h continuous exercise at an exercise intensity corresponding to Fatmax on post-exercise fat oxidation kinetics.

Methods
On a first visit, 16 healthy and moderately trained subjects (7 men and 9 women) performed a graded test to exhaustion on a treadmill (Incr), with 3-min stages and 1 km/h increments. Fat oxidation rates were determined during submaximal exercise stages using indirect calorimetry and plotted as a function of exercise intensity. A mathematical model (SIN) (1), including three independent variables (i.e. dilatation, symmetry and translation), was used to characterize and quantify the shape of fat oxidation kinetics and to determine Fatmax and MFO. On a second visit, the volunteers performed a 1-h continuous exercise at Fatmax (CONT) followed by a submaximal (i.e. until respiratory exchange ratio (RER) reached 1) graded test (IncrC) in order to determine post-exercise fat oxidation kinetics. All tests were performed under fasting conditions. Data are reported as means ± SE.

Results
Following CONT performed at 57 ± 3 %VO2max, RER during IncrC was lower at each stages compared with Incr (P < 0.05). Absolute fat oxidation rates during IncrC were significantly greater from 20 to 75 %VO2max compared with Incr (P < 0.05). A higher MFO was found in IncrC than in Incr (0.50 ± 0.03 vs. 0.41 ± 0.03 g/min, P < 0.001), whereas Fatmax tended to occur at higher intensity (58.7 ± 2.8 vs. 54.4 ± 2.9 %VO2max, P = 0.06, respectively). The three independent variables of SIN that characterize the shapes of fat oxidation kinetics were however not significantly different between Incr and IncrC (P > 0.05).

Conclusion
These results indicate that 1-h of continuous moderate-intensity exercise leads to a partial muscle glycogen depletion (4) that promotes greater post-exercise fat oxidation rates over a wide range of intensities and significantly increases MFO. Variables of SIN however show no difference in the shape of fat oxidation kinetics between before and after exercise. A longer duration exercise leading to higher glycogen depletion might increase MFO and Fatmax to a larger extent and therefore modify the pattern of fat oxidation kinetics.

5. Weltan et al.,
Muscle length-dependent fatigue has been observed in different muscles, as the quadriceps femoris muscle group (1), the elbow flexor muscles (2) and the tibialis anterior muscle (2). In the present study length-dependent fatigue of the triceps surae muscles was investigated and related to potential differences in oxygen consumption (1). In addition, by measuring muscle oxygen consumption (mVO2), the effect of different ankle angles and different contraction intensities on the relative contribution of the gastrocnemius (GAS) and the soleus (SOL) muscles to the produced torque was estimated. During isometric plantar flexion contractions at different torque levels (40, 70 and 100% of maximal torque capacity (MTC)) near-infrared spectroscopy (NIRS) was used to measure mVO2 of the gastrocnemius lateralis (GL), SOL and the gastrocnemius medialis (GM) muscles. In addition the endurance time was determined during contractions at 70% MTC. The measurements were performed both at 20° plantar flexion (PF, short muscle length) and at 15° dorsal flexion (DF, long muscle length). The endurance time was longer at short (58 ±15.8 s) than at long muscle length (37 ±12.7 s) (P < 0.01). In addition, at all torque levels, mVO2 was smaller at short compared to long muscle length. At 70 and 100% MTC no interaction effects between ankle angle and muscle were found. This means that the differences in mVO2 between long and short muscle length were similar for GAS and SOL, probably indicating a similar relative contribution of GAS at both muscle lengths. However, at each of the ankle angles, significant interactions were observed between torque level and muscle. With increasing torque level, mVO2 increased more in GAS than in SOL, probably signifying a greater recruitment of GAS at higher torque levels. In conclusion, the fatigue resistance of the triceps surae muscles is greater at a relatively short than at a longer muscle length. The lower mVO2, and therefore likely the lower energy consumption, at short muscle length seems to contribute to this length-dependent fatigue. The relative contribution of the different triceps surae components seemed to be similar at both ankle angles and therefore this did not seem to contribute to the greater fatigability of the triceps surae muscles at long muscle length. Although no differences in the relative contribution to the plantar flexion torque were found between the ankle angles, in both PF and DF the relative contribution of GAS seemed to increase with increasing torque.

ENERGETICS OF CONSTANT BALLAST BREATHE-HEIGHT DIVING IN HUMANS
Frisoni, V., Tam, E., Moia, C., Ferretti, G.
Faculty of Medicine University of Brescia, Italy and University Medical Center Geneva, Switzerland, Italy
The energetics of constant ballast breath-hold diving at maximal speed was investigated on five top level breath-hold divers (age 37±2 years, mass 71±9 kg; maximal oxygen consumption 3.10±0.45 L/min). Each of them performed constant ballast breath-hold dives to 30 m in the sea (water temperature 24 °C) at their maximal diving speed. Before and after the trials, we measured oxygen volume in lungs and arterial blood, oxygen saturation, and blood hemoglobin and lactate concentrations. This allowed determination of aerobic (lungs and arterial blood) and anaerobic lactic energy expenditure. The aerobic energy from venous blood oxygen was estimated assuming an 5 L blood volume and invariant arterio-venous oxygen difference. The aerobic energy taken from tissue oxygen stores was estimated assuming that tissues contain up to 200 ml of oxygen overall. Anaerobic lactic acid energy was also accounted for, assuming that the obligatory component of the oxygen deficit has a time constant of 23.2 s. Lung oxygen content after the trials decreased from 95±5 ml 100 ml STPD to 40±21 ml 100 ml STPD. Blood and tissue oxygen content decreased to 543±261 and 157±34 ml. Lactate increased by 2.78±1.62 mM, yielding energy for 578±303 ml of oxygen equivalents. The total energy used (E) during each trial was obtained by adding the contributions of each energy source and resulted equal to 1959±571 ml of oxygen equivalents. When expressed per unit of time, it resulted equal to 2.31±1.18 L/min (75% of maximal oxygen consumption). This relative power, above the subjects’ lactate threshold, suggests that lactate accumulation is due to exercise intensity (lactate accumulated during the exercise transient) rather than to the occurrence of diving response mechanisms.

INFLUENCE OF DISTANCE FEEDBACK AND PRIOR EXPERIENCE ON PACING STRATEGY DURING A 4KM CYCLE TIME TRIAL
Mauger, A., Jones, A., Williams, C.
University of Exeter, United Kingdom
Background: The Central Governor Model, based on Ulmer’s theory of teleoanticipation, is proposed to work as a safety mechanism for the body, acting through a system of central control. The brain uses a combination of prior experience and distance knowledge to work in a feedforward manner, so that a pacing strategy is set before exercise commences which ensures the bout is completed in the most efficient manner. Afferent feedback from the periphery constantly allows the central governor to make changes to this pacing strategy based on peripheral changes. Despite the apparent importance of distance knowledge and prior experience, little research has been completed in this area.
Aims: To determine the importance of distance knowledge, distance feedback and prior experience on the setting and maintenance of a pacing strategy.
Methods: Eighteen well-trained male cyclists were randomly split into a control (ICON) or experimental group (EXP) and performed four consecutive 4-km time trials (TT), separated by 17 minutes. The CON group received prior knowledge of distance to be cycled and received distance feedback throughout each TT. The EXP group received neither prior distance knowledge nor feedback, but knew that each TT was of the same distance. During each TT power output, mean and peak speed, VO2, heart rate and [EMG of the vastus lateralis (VL)] was recorded.
Results: The EXP group were significantly slower than the CON group to complete TT1 (P< 0.05). From TT2 onwards no significant differences in time to completion were found between groups. The magnitude of the difference between groups for TT2, TT3 and TT4 reduced with each consecutive time trial, characterised by successively faster times in the EXP group. By TT4 there was <1% difference in time to
completion between groups (CON TT1 367.4 ± 21 s; EXP TT1 409.4 ± 45.5 s; CON TT2 373.8 ± 19.7 s; EXP TT2 389.7 ± 30.2 s; CON TT3 375.1 ± 18 s; EXP TT3 383.7 ± 26.2 s; CON TT4 373.9 ± 20 s; EXP TT4 373.8 ± 14.4 s). Mean speed and mean power output showed a similar profile to that of time to completion across TT's, but peak power output was significantly different between groups for TT1, TT3 and TT4 (p < 0.05). iEMG tracked changes in power output during each TT in the CON and for TT3 and TT4 only in the EXP. Conclusion: The progressively improving times for completion over TT’s in the EXP shows that distance feedback is not essential in achieving optimum TT times. Prior experience of an unknown distance appears to allow the creation of an internal or relative distance that is used to create a pacing strategy. When sufficient prior experience is attained in the absence of distance knowledge and feedback, the pacing strategy created on the basis of this internal, relative distance appears to be as successful as when distance knowledge and feedback are available.

OP-PM08 Physiology 8 - Chronic conditions

HAEMATOLOGICAL PROFILES OF ELITE EAST AFRICAN ATHLETES OVER A NINE YEAR PERIOD

Ojiambo, R., Mohammad, Y., Fudge, B., Kingsmore, D., Parisotto, R., Magnus, L., Pitsiladis, Y.
University of Glasgow, United Kingdom

The World Anti-Doping Agency (WADA) is currently considering use of abnormal blood profiles that can reflect blood manipulation and therefore an anti-doping rule violation. However, chronic altitude exposure also has the potential to influence indirect indices of blood doping. While most Kenyan and Ethiopian athletes live and train in their native east African regions, they must frequently travel to lower altitudes for competitions. There is therefore an urgent need to consider the natural changes in haemopoietic indices from altitude exposure in an attempt to differentiate these responses from blood doping. Methods: 649 blood profiles collected between 1999 and 2007 from 289 (192 males, 97 females) elite athletes from east Africa were screened using the transversal [2nd generation, n=289; [1]] and longitudinal [3rd generation, n=33; [2]] approaches to erythropoietin (EPO) screening in athletes. Blood indices were compared at altitude and at sea level. Seasonal variations in haemopoietical parameters and urinary test results for EPO were also considered. Results: Mean haemopoietical indices of elite east African athletes were within published cut-off thresholds for indirect blood markers of doping. The blood profiles of all athletes varied considerably over time (i.e. coefficient of variation for haemoglobin, Hb; CV: 0.2-11.7%, haematocrit, Hct; CV: 2.0-13.9%, Reticulocytes; CV: 9.4-74.9%, and OFF-hr CV 3.8-36.5%) and attained peak levels at altitude exposure, peak Hb (range: 170-191 g/L), peak Hct (range: 49-63%). During the assessment period, the Hb cut-off of 170 g/L for males and 160 g/L for females was exceeded at least once (range: 1-4) by 14.2% (n=41) of athletes at altitude, whereas 4.2% (n=12) of athletes exceeded the Hb cut-off at sea level. At altitude, 11.1% (n=32) of athletes exceeded the Hct cut-off of 50% for males and 47% for females on at least one occasion compared to 3.5% (n=10) of athletes at sea level. 1.4% (n=4) of athletes exceeded the OFF-hr cut-off of 133 for males and 123 for females at altitude (OFF-hr range: 129-143). No athlete exceeded the OFF-hr cut-off threshold at sea level. For reticulocytes, 4.2% (n=12) of athletes exceeded the > 2.0% cut-off at altitude and 2.1% (n=6) at sea level. 51.5% (n=33) of the athletes exceed the 1 in 50 cut-off threshold for OFF-hr scores and Hb 2 scores and would therefore be deemed suspicious. During the study period, 180 urine samples were analysed for EPO with 1 positive test for a female athlete. Conclusions: A significant number of elite east African athletes tested had substantially elevated haemopoietical parameters and considerable fluctuations from historical baseline values reflecting numerous confounding factors such as ethnicity and altitude exposure.

SIMILAR MAXIMAL FAT OXIDATION DURING ACUTE EXERCISE IN PATIENTS WITH TYPE 2 DIABETES, OBESE AND LEAN CONTROLS

Larsen, S., Ara, I., Raabøl, R., Stallknecht, B., Dela, F., Helge, J.
University of Copenhagen, Denmark

Introduction:
Insulin resistance and type 2 diabetes has been associated with an imbalance between availability and oxidation of fatty acids. The aim of the present study was to examine whether maximal fat oxidation (MFO) was attenuated in patients with type 2 diabetes (T2DM) compared to obese and lean controls. Methods:
Male subjects (age: 43 +/- 2 yrs) were recruited into three groups. Healthy normoglycemic obese (n = 8) and lean (n = 7) controls and T2DM (n = 8, time since diagnosis: 4.1 +/- 0.5 yrs). The subjects were examined fasted on two occasions. Pre-tests included an OGTT, a DEXA scan and an incremental VO2 max test. On a separate day, MFO was determined using an incremental bicycle test, starting at 60 W for 8 minutes followed by 35 W increases every 3rd minute [1]. MFO was calculated with the application of indirect calorimetry using Frayn’s formula [2].

Results:
The groups were matched for age. BMI and % body fat were lower (P<0.05) in lean compared to obese and T2DM (24.7 +/- 0.6 vs. 31.7 +/- 1.4 vs. 31.9 +/- 1.7 kg/m^2) and 122.7 +/- 11. vs. 32.0 +/- 1.3 vs. 32.6 +/- 2.2 %, respectively. VO2 MAX was higher (P<0.05) in lean compared to obese and T2DM (42.4 +/- 1.1 vs. 30.9 +/- 1.8 vs. 26.2 +/- 1.5 ml/kg &#829;min), respectively. No difference was seen in the above mentioned parameters between obese and T2DM. No difference was found in basal plasma FFA concentration between lean, obese and T2DM (345 +/- 54 vs. 365 +/- 48 vs. 377 +/- 33 pmol/l). MFO during bicycle exercise was not different between the groups (Lean: 0.30 +/- 0.02; Obese: 0.31 +/- 0.04; T2DM: 0.33 +/- 0.05 g/min). The intensity at which MFO occurred (FatMax) was not different between groups (Lean: 0.30 +/- 0.02; Obese: 0.31 +/- 0.04; T2DM: 0.33 +/- 0.05 g/min). The intensity at which MFO occurred (FatMax) was not different between groups (Lean: 0.30 +/- 0.02; Obese: 0.31 +/- 0.04; T2DM: 0.33 +/- 0.05 g/min). The intensity at which MFO occurred (FatMax) was not different between groups (Lean: 0.30 +/- 0.02; Obese: 0.31 +/- 0.04; T2DM: 0.33 +/- 0.05 g/min). The intensity at which MFO occurred (FatMax) was not different between groups (Lean: 0.30 +/- 0.02; Obese: 0.31 +/- 0.04; T2DM: 0.33 +/- 0.05 g/min).

Discussion:
MFO and FatMax were similar between the groups. Prior studies have shown that trained subjects have a higher MFO compared to untrained and the relative workload where it occurred was higher (3). Thus, in significant contrast to our expectations MFO was not lower in T2DM
compared to obese and lean controls, despite a higher VO2 MAX in lean. A higher FatMax was expected in lean controls, but in fact a trend was seen here for the opposite, compared to T2DM.

Conclusion:
Surprisingly no difference was seen in MFO and FatMax between T2DM, obese and lean subjects.

STRUCTURAL REMODELING OF HUMAN SKELETAL MUSCLE WITH CHRONIC UNLOADING

Narici, M., Flueck, M., Seynnes, O., De Boer, M., Maganaris, C., Rennie, M.
Manchester Metropolitan University, University of Nottingham, United Kingdom

Exposure to actual or simulated microgravity is known to lead to muscle atrophy and weakness. Recent evidence obtained in our laboratories on young men (n=18) undergoing chronic unloading shows that muscle atrophy involves rapid remodeling of muscle architecture. Indeed, vastus lateralis (VL) fibre fascicle length (Lf), assessed by ultrasound, was found to decrease by 5.5% after just 10 days of unilateral lower limb suspension (ULLS) and by 9% after 35 days of bedrest. This decrease in Lf, indicating a rapid loss of sarcomere in series, was associated with a concomitant decrease in concentration (-20%) and activity (-30%) of focal adhesion kinase (FAK, an integrin-associated phosphoprotein involved in mechanotransduction), measured on VL muscle biopsy samples obtained in the same individuals. Furthermore, using stable isotopes, we found that myofibrillar fractional rate of protein synthesis measured on the same biopsy samples dropped by 50% within 10 days of unloading. We conclude that sarcomere remodeling in response to unloading in humans, is a very fast process involving significant changes in cytoskeletal proteins involved in mechanotransduction. The results also suggest that countermeasures aimed at preventing muscle atrophy should start from the very early phases of the disuse period. Financial support of ASI (OSMA Bed Rest project) and ESA (ULLS study) is acknowledged.

THE EFFECTS OF AEROBIC TRAINING ON LEPTIN, CORTISOL AND SERUM TESTOSTERONE LEVELS IN OBESE AND LEAN MEN

Peeri, M., Boghrabadi, V.
Islamic Azad University Central Tehran Branch, Iran

The purpose of this study was to determine the effects of aerobic training on leptin, cortisol and serum testosterone levels in obese and lean men. To this end healthy and volunteers men, who had 25 to 35 years old were asked to complete a questionnaire including individual characteristics, health history, amount of physical activity and smoking. Body mass index(BMI) were measured using the body composition analyzer and 40 untrained people were selected and divided in two groups: 20 people with 30 to 35 kg/m² BMI in obese group and 20 people with 16 to 18.5 kg/m² BMI in lean group.

To measure the leptin, cortisol and serum testosterone levels by the radioimmunoassay (RIA) method, blood samples were taken 2 days before starting of aerobic training program, prior to breakfast time. Both groups performed aerobic training program including running with 65-85% of individual maximum heart rate on treadmill in 2 months consecutives, 3 sessions a week, and 30 minutes per session. Then were taken blood samples 2 days after the end of training program and all the parameters in both groups were measured again. The analysis of data before and after aerobic training using T test particularly in correlated and independent groups showed that: There was significant decrease among weight (p<.001), BMI (p=.012) serum leptin(p<.001) and significant increase cortisol(p=.027) in obese group. Also was significant decrease among serum leptin (p=.004) and significant increase BMI (p=.008), and cortisol (p=.070) in lean group. Moreover the result of between obese and lean groups, indicated that serum leptin levels (p=.000), BMI (p<.001) and weight (p<.001) was significantly higher and serum testosterone (p=.009) were significantly reduced in obese group as compared to lean group.

Considering the results, it seem that aerobic training via alternating in some hormones including leptin, cortisol, and testosterone has an important role to regulation of body weight. Meanwhile probably there are different mechanisms which effects the regulation of body weight in obese and lean groups to response aerobic training.

CHILDREN’S PARTICIPATION IN VOLUNTARY SPORT AS A PROTECTIVE MEASURE AGAINST OVERWEIGHT AND OBESITY

Stockel, J., Groenved, A.
University of Southern Denmark, Denmark

Introduction
As the number of children who are overweight or obese grows, a variety of approaches, including ways to increase physical activity, are necessary to address the problem. Recent studies on children’s physical activity and children’s health have shown that children from low socioeconomic backgrounds are less likely to be sport active and more likely to become sedentary, overweight and socially excluded.

In a Danish 3 year intervention program the aim was to improve the physical activity level and welfare among sedentary 6-10 year old children in public after school day care institutions. The intervention included 2,500 children from 25 county districts on the island of Funen who were given the opportunity for participating in extra 2-4 hours of physical activity per week.

Methods
Base line (N=1,373) and end line (N=1,176) questionnaires with 6-10 year old children were filled out with the assistance of pedagogues. Questionnaire items included height, weight, sport participation and motivation for play and sporting activities and reasons for not playing or doing sports.

Results
Findings show that children who are not sport active in a sports club were one and a half times as likely to be overweight or obese (OR=1.48, CI (1.14,1.93) adjusted for age and sex). Results show that 15-20 % of sport active children are overweight or obese opposed to
20-30% of non-sport active children. Boys were less likely to be overweight and obese than girls. The inactive girls aged 6-7 showed significantly higher tendency to be overweight than the 8-9 year olds. The average percentages of overweight and obese were relatively stable throughout the intervention period (18.6% to 19.1%). The active children were also more likely to be using self transport such as biking or walking.

Discussion

Though findings indicate that the sport active children are less likely to be overweight and obese, it has not been sufficiently investigated whether it relates to the actually energy expenditure while doing sports in a sports club or the indirect effect of social inclusion. It may be hypothesised that the inactive children may find it harder to overcome social barriers and subsequently are unable to compensate for the lack of physical activity in other settings such as school breaks, school sport, self-organised physical activity or family activities.

COOLING DURING THE EXERCISE IN SPINAL CORD INJURED INDIVIDUALS: A PILOT STUDY

Kocjan, N., Perret, C.
EMPA St. Gallen & Swiss Olympic Medical Centre, Swiss Paraplegic Centre, Nottwil, Switzerland

Introduction

Individuals with spinal cord injury display impaired regulation of body temperature against warmth and cold, when compared to able-bodied individuals. Namely, the effectiveness of their thermoregulatory response corresponds to the location of injury and reflects the amount of nervous system preserved. Consequently, when exercising in warm environment, thermal imbalance and risk for heat injury are likely to occur earlier than in able-bodied individuals (Price 2006). Thus, it is suggested that external cooling applied during situations of thermal stress, e.g. exercise, could favour thermal balance and avoid such risk. This was under investigation in the present study, where external cooling was provided by a lightweight portable cooling garment (PCG).

Methods

A tetraplegic (TP), a high paraplegic (HP) and a low paraplegic (LP) participated in the study. Ambient conditions were set at 30°C and 80% relative humidity, with wind velocity of 6 m/s over a subject. The TP subject was asked to perform 15 minutes of wheelchair ergometry, while HP and LP subject were asked to perform 30 minutes. Subjects visited laboratory three times where: i) no cooling (control), ii) wearing PCG, without cooling (no-cooling) and iii) wearing PCG, with cooling (cooling) was applied. Trials began with five minutes warm up and, subsequently time trial exercise was performed. During trials body core temperature (Tc) and heart rate (HR) were continually monitored. Furthermore, thermal perception and thermal comfort were assessed after each five minutes. Body weight was noted before and after the exercise.

Results

At the end of the cooling trial, the increase of Tc in TP was 0.5°C lower than that observed in no-cooling trial, and 0.3°C lower than observed in the control trial. Furthermore, cooling in HP lowered the increase in Tc by 0.2°C when compared with no-cooling and by 0.4°C when compared with control trial. We did not obtain sufficient data for comparison in LP. On most occasions investigated, thermal perception and thermal comfort was promoted in cooling trial, when compared with control trial, but not always when compared with non-cooling trial. Furthermore, in HP increase in HR was lower when cooling was applied, but this was not the case in LP. Due to autonomic reflexes that occurred in TP, data on HR are not comparable. In all subjects, the body weight loss was the lowest after the cooling trial.

Conclusions

In TP and HP cooling slowed an increase of Tc and promoted unfavourable subjective thermal perception. Furthermore, it positively influenced body weight which is likely to result in promoted fluid balance. A positive effect of improved thermal balance was observed also on HR of HP, though not in LP, which might suggest the role of lesion level. Thus, it is suggested that cooling during the exercise favours thermal balance in individuals with spinal cord injury.

OP-PS02 Psychology 2

THE TRANSITION OF YOUTH PLAYERS IN ELITE EUROPEAN FOOTBALL CLUBS: STRUCTURES, PHILOSOPHIES AND WORKING PRACTICES

Relvas, H., Richardson, D., Gilbourne, D., Littlewood, M.
Liverpool John Moores University, United Kingdom

Introduction

Professional football clubs are enterprises looking for sportive and financial results. Clubs aspire to spend less but accumulate profit for long term sustainability. However, football is an expensive business. The increased commercialisation of the game alongside spiralling transfer fees has encouraged clubs to invest in youth development.

Objectives

This study forms part of a research project that explores the preparation and promotion of youth footballers to the professional environment in elite European football clubs. This paper explores the influence of a club’s organisational structure, philosophy and working practices in the transition of young players from the youth to professional environment.

Material and Methods

Face-to-face semi-structured interviews were conducted with the Head of Youth Development (or equivalent) within elite football clubs (n=26) across countries in Europe (n=5). Interviews were transcribed verbatim and analysed utilising the principles of content analysis (Biddle et al., 2001). Interviews were supplemented with additional information sourced directly from club administrators and club websites.

Results

Specific ‘development’ practices are not peculiar to, or a characteristic of, any one particular country. All clubs identified that the main objective of the youth department was to ‘produce players for the 1st Team’. Player’s personal development (i.e., social and academic)
and financial reward (i.e., received for players sold) were also identified as specific objectives. Only Swedish clubs presented a National orientation towards the development of players. All clubs tend to employ similar staff, but the operational roles of such staff often differ between both club and country. Such roles are dependent on the club’s overall philosophy of practice (i.e., typically guided by the club Chairman, President and/or Board). The communication process and proximity of the 1st Team and the youth department proved to be difficult.

Discussion and Conclusions

The secret of a successful youth development programme appears to be based on three aspects; stability, proximity and communication. Moreover, the apparent difficulty in communication between the 1st Team and the youth departments seem to contribute to dissatisfaction amongst the youth staff members and a subsequent lack of cohesiveness between youth and professional environments. Poor communication and incoherency is likely to hinder a successful player transition to the professional team.

Findings showed a high turnover of staff responsible for youth development and a lack of clearly defined roles and/or responsibility. The turnover of staff and a lack of clearly defined roles and/or responsibility between both club and country. Such roles are dependent on the club’s overall philosophy of practice (i.e., typically guided by the club Chairman, President and/or Board). The communication process and proximity of the 1st Team and the youth department proved to be difficult.

Moreover, the apparent difficulty in communication between the 1st Team and the youth departments seem to contribute to dissatisfaction amongst the youth staff members and a subsequent lack of cohesiveness between youth and professional environments. Poor communication and incoherency is likely to hinder a successful player transition to the professional team.

PEER MOTIVATIONAL CLIMATE IN YOUNG ATHLETES AND PERCEIVED AUTONOMY SUPPORT FROM ADULTS

Hein, V., Jöösaar, H.
University of Tartu, Estonia

Previous research based on goal achievement theory has shown that perceived autonomy support from coaches among young athletes is related with perceived motivational climate (Sarrazin, et al., 2007). The effect of perceived autonomy support from significant others (e.g. parents) on motivational climate has remained unclear. The present study aimed to retest Peer MCYSQ questionnaire (Ntoumanis, & Vazou, 2005) in Estonian young athletes and to estimate how perceived autonomy support from the coaches and parents is related with dimensions of perceived peer motivational climate.

The perceptions of the peer motivational climate (Peer MCYSQ) were measured in 747 young athletes aged 12 to 18 years from different sport clubs in Estonia. Athletes’ perceptions of the autonomy-supportive behaviors exhibited by their coaches and perceived autonomy support from parents were assessed using the short version of the Sport Climate Questionnaire (SCQ). Structural equation modelling procedures were used. The goodness-of-fit indices that were used to test the adequacy of the 5-factor structure model of the Peer MCYSQ improvement, relatedness support, effort, intra-team competition and intra-team conflict supported, however, the 4-factor structure model. In the 4-factor model improvement and relatedness support scales entered into one factor. The fit indices of the structural equation model about the effect of perceived autonomy support from adults on peer perceived motivational climate were acceptable [NNFI = 0.98, CR = 0.98 and RMSEA = 0.04]. Perceived autonomy support from coach was positively related with improvement/relatedness and effort and negatively with intra-team conflict. Perceived autonomy support from parent was related with improvement/relatedness, effort and intra-team competition. Perceived autonomy support from coach influenced the peer motivational constructs like improvement/relatedness and effort more than perceived autonomy support from parent. Intra-team competition was affected by the perceived autonomy support from parent, whereas the intra-team conflict by the perceived autonomy support from coach.

From an applied perspective, these results highlighted beyond the role of the perceived autonomy support from coach also the perceived autonomy support from parent on peer motivational climate of young athletes.

CHANGES IN MENTAL DISTRESS IN PATIENTS WITH CHEMICAL DEPENDENCE FOLLOWING INDIVIDUALISED PHYSICAL TRAINING

Mammen, A., Pallesen, S., Martinsen, E.
Sogn og Fjordane University College, Norway

Physical training has been used in the treatment of chemical dependence for several decades, but the training is usually not adapted to the individual patient. This may be of importance, as the development of long-lasting, good training habits is easier to accomplish with a suitable training load, adapted to the individual. Thirty-six persons, seven females, who took part in a drug rehabilitation project, served as participants. Pre-post measurements comprised VO2peak, lactate profile, depression (Beck Depression Inventory, BDI), anxiety (Beck Anxiety Inventory, BAI), social phobia (Brief Social Phobia Scale, BSPS total), psychiatric symptoms (Symptom Checklist-90-R-Global Severity Index, SCL-90R-GSI) and alcoholism (Short Michigan Alcoholism Screening Test, SMAST). The duration of the intervention, median (inter-quartile range), was: 282 (114) days with training together with an assigned training partner who had taken a course in sport science and psychiatry. The training was conducted on a regular schedule, with a variety of activities adapted to the preference of the participants. Intensity zones were established based on the first lactate threshold test. VO2peak showed little improvement (mean ± SD: 4 ± 11%) and the lactate threshold performance increased moderately (11 ± 15%). Participants who increased their VO2peak (n=25) also showed improvements in terms of moderate to large effect size (95%CI on BDI: 0.81 (0.22-1.38), BAI: 0.82 (0.22-1.39), BSPS total: 0.73 (0.15-1.29), and SCL-90R-GSI: 0.96 (0.35-1.53). Participants who had unchanged or decreased VO2peak (n=11) showed improvements in terms of effect sizes of small magnitude (<0.28) on BDI, BAI and SCL-90R-GSI. On BSPS total, this group worsened, shown by a negative effect size of -0.41 to -1.25. The results suggest that improvement of physical capacity is necessary for improving mental health.

PRELIMINARY VALIDATION WITH ELDERLY PEOPLE OF THE PORTUGUESE SHORT CLINICAL VERSION OF THE PHYSICAL SELF-PERCEPTION PROFILE

Ferreira, J., Fox, K., Cruz, M., Salgueiro, T.
Universidade de Coimbra and University of Bristol, Portugal

The PSPP (Fox & Corbin, 1989) is one of the most widely used instruments to assess self-perceptions in the physical domain and several studies have confirmed the hypothesized hierarchical three-level organization. Four sub-domains contribute to a super-ordinate construct, termed physical self-worth (PSW), which in turn produces moderately strong relationships with global self-esteem. The 30-item PSPP is often seen as too long for use as an outcome measure in clinical studies and omits some sub-domains of self-perception that may be important for elderly groups or those with infirmity. Recent work was published with an English language 18-item short clinical version the PSPP-SC. This showed good factors structure and reliability with an elderly population (Fox et al., 2006). The purpose of this study was to provide preliminary evidence of reliability and validity of a new Portuguese version - the PSPP-SC, under development with elderly groups. The participants were elderly people (N=657) from central Portugal. Two samples were used. Sample A (n=257) were 184 females (74 69±6.7) yrs and 73 males (75 12±6.6 yrs) attending different Social Service and Welfare institutions and local clubs with exercise programmes for elderly groups. Sample B subjects (n=400) were 200 females (74 14±7.4 yrs) and 200 females (74 21±7 yrs) also attending similar programmes. EFA (with varimax rotation) was used in Sample A participants to establish the independence and integrity of the proposed five sub-domain scales. The results of the exploratory factor analysis conducted by gender revealed five factors that explained a total of 66.75% of the variance for female and 75.74% for male Portuguese elderly people among the sub-items. However, several cross-loadings were found between factors. The Physical Function, Physical Health and Attractive Body sub-scales showed good internal consistency with coefficient Cronbach alpha values of 76, 63 and 70 for females and 77, 77 and 70 for males. The Sport Competence and Strength subscales presented the lowest levels of internal consistency with alpha values of .50 and .45 for females and 48 and .52 for males. A CFA was run with sample B subjects to confirm the goodness of fit for the original model in both groups. CFI, GFI
and AGFI ranged from .88 to .90 in females and from .74 to .83 in males. SRMR values were .057 for females and .089 for males. Portuguese data did not replicate the psychometric integrity of the PSPP-SC and did not support the widespread use of this version of the instrument in Portuguese elderly groups. The analyses indicated that Physical Function was clearly defined both in female and male groups while Attractive Body was defined in the female group. This may be due to the salience of these sub-domains for the lives and autonomy of Portuguese elderly people. Physical Health, Physical Strength and Physical Competence have some items which do not load adequately and require further attention.

OP-TT03 Training and Testing 3

VALIDATION OF THE OXYCON MOBILE PORTABLE ERGOSPIROMETRIC DEVICE DURING INCREMENTAL MAXIMAL EXERCISE TEST

De Pauw, K., Rietjens, G., Roelands, B., de Geus, B., Meeusen, R.
Vrije Universiteit Brussel, Belgium

Introduction
The portable breath-by-breath system Oxycon Mobile® (OM) records parameters such as VE, VO2 and VCO2, and has been validated against the Oxycon Pro® (Perret et al, 2006), but to our knowledge not against the gold standard Douglas Bag (DB). The purpose of this study was to test the validity of the OM against the DB, during a maximal incremental exercise test.

Methods/Instruments
Twelve well-trained healthy male subjects (Age 22 ± 1 y; VO2max 4.08 ± 0.59 l/min) completed an incremental test on an electromagnetically braked cycle ergometer (Lode Excalibur Sport, Groningen, the Netherlands) in an air conditioned laboratory with constant environmental conditions (temperature 21 °C, humidity between 50 % and 60 %).

The test protocol started at 95 Watt and was increased by 35 Watt every 5 minutes until volitional exhaustion. After 3 minutes in each step the OM was disconnected and a DB (Relitech, the Netherlands) was filled with air during 30 seconds to 1 minute (depending on the ventilation).

Results
Compared to the DB the OM showed significantly higher values for the VE at 200 Watt (P < .05) and for the VO2 at 95 W (P < .05) during the incremental exercise test. No significant differences for the VCO2 were found. High correlations were found between the values of the DB and OM (VE: P < .001, r² 0.956; VO2: P < .001, r² 0.977; VCO2 P < .001, r² 0.971). Bland and Altman analysis of validity demonstrated minimal bias and low standard deviations.

Discussion/Conclusion
We used the DB method as the reference system. Still it is important to notice that the DB technique is not without problems (such as diffusion of gases through the bag, and gas remaining trapped inside the bag, especially in the rigged neck area). Modern systems also have their problems and one of the greatest problems, especially in breath-by-breath systems, is the exact alignment of the gas flows with gas analysis (Macfarlane, 2001).

A comparison of measurements between two devices is most accurately when they are placed in series. In this study we did not place the devices in series because of the mobile features of the OM. Unlike the DB method, this portable breath-by-breath system can be used for accurate and continuous determination of ventilatory variables during exercise.

VALIDITY OF A RESPIRATORY SNORKEL FOR DETERMINATION OF OXYGEN UPTAKE KINETICS IN SWIMMING

Reis, J., Millet, G., Vleck, V., Alves, F.
Faculty of Human Kinetics - Lisbon, Portugal

In pursuit of direct measurement of cardio-respiratory parameters in swimming Toussaint et al. (1987) developed a respiratory and vegetable system that was shown to be valid and to only slightly increase the hydrodynamic drag. The more recent version of this respiratory snorkel (RS) (Aquatrainer, Cosmed, Roma, Italy) connected to a breath-by-breath (BxB) gas analyser (K4b2, Cosmed, Roma, Italy) was evaluated by Rodriguez et al (2008). It was reported that although the Fi O2 was significantly larger when measured with the RS, there were no significant differences in VO2 and VCO2 between the RS and a mechanical gas exchange simulation system. However, in what concerns oxygen uptake kinetics, the use of the RS has not yet been evaluated.

The purpose of this study was to compare the parameters of the VO2 kinetics in constant-power exercise, using a conventional face mask (CM) or a respiratory snorkel (IRI) designed for breath-by-breath analysis in swimming. Ten trained triathletes (29.3±8.3 yrs, 67.5±7.3 kg, 177.2±6.9 cm) performed two testing sessions involving an incremental test to exhaustion for determination of VO2max and Ventilatory Threshold (VT1) and two 8-min constant load exercise at 25% [= VT1 + 0.25 x (VO2max - VT1)] in each condition. The VO2 kinetics parameters ηd1, ηa1, A1, ηd2, ηa2, A2, i.e. time delay, time constant and amplitude of the primary phase and slow component, respectively) were modelled with two exponential functions (Borraní 2001), which also incorporated the determination of an individual snorkel delay (ISD) in the case of the RS tests. This time was calculated as the difference between the start of the exercise and the time when the following breaths summed a tidal volume superior to the outlet tube volume, therefore making the VO2 data to be exercise representative. Only ηd1 was significantly different between RS and CM (13.80±1.77 and 8.95±2.99 s, respectively) due to the delay introduced by tube’s volume. Otherwise, the variability of the primary phase parameters was not different between RS and CM.
In conclusion, direct measurement of VO2 in swimming for estimating VO2 kinetics is appropriate and comparable to terrestrial activities (i.e., running, cycling), as long as a suitable numerical method is used to model the data, since the use of a respiratory snorkel does not interfere with the kinetic parameters obtained in heavy intensity constant load exercise.

TIME COURSE OF ADAPTIVE RESPONSES TO ONE YEAR OF AEROBIC ENDURANCE TRAINING
Scharhag-Rosenberger, F., Meyer, T., Walitzeck, S., Kindermann, W.
University of Saarland, Germany

Purpose: Only limited information is available about the time course of adaptive responses to an aerobic endurance training program during the first year after its onset. Long-term studies observed training regimens which were not suitable for health maintenance and promotion, i.e. exercise intensities and volumes were too high or increased markedly over time. Therefore, the magnitude and the time course of adaptive responses to one year of aerobic endurance training with a constant heart rate (HR) prescription was investigated in this study.

Methods: Eighteen previously untrained subjects (42 ± 5 years, BMI: 24.3 ± 2.5 kg/m², maximal oxygen uptake (VO2max): 37.7 ± 4.6 ml/min/kg) completed a one-year walking or jogging program 45 min/day/3 days/week at 60% of their pre-training HR reserve. Training data were recorded in training HR monitors to assess compliance compared to actual training intensity of HR and gas exchange variables. HR and gas exchange variables were conducted prior to the training program and after 3, 6, 9, and 12 months of training. Additionally, submaximal 4-stage tests (only simultaneous HR measurements) were performed on an indoor track every 2 weeks during the first 3 months and once a month in the remaining time. Results: Subjects trained on average of 48 ± 2 min/day on 2.8 ± 0.2 days/week and compliance was not different during the 4 periods between the treadmill tests (p > 0.13). Mean blood lactate concentration during the training sessions decreased significantly from 1.37 ± 0.18 mmol/l in the 11th week to 1.15 ± 0.24 mmol/l in the 47th week (p < 0.01). After 12 months, VO2max increased by 5.7 ± 4.1 ml/min/kg (p < 0.001). After 3, 6, and 9 months, 58, 75, and 84% of the total increase were reached, respectively. Resting HR was observed to decrease by 9 ± 6 /min (p < 0.001) after 12 months, and 47 and 100% of this change had occurred after 3 and 6 months, respectively. During the study, HR on submaximal stages of the treadmill test decreased by 11 ± 7 /min on average (p < 0.001). After 3 and 6 months 93 and 100% of this change were observed, respectively. The submaximal 4-stage tests revealed that submaximal HR did not change significantly beyond the 9th week of training (p > 0.59). Conclusions: Beginners in recreational endurance training are advised to increase their training stimulus after 6 months because all chosen descriptors of endurance capacity showed at least 75% of their one-year-changes within this period of time. It cannot be decided from this study whether an increase in intensity or in the volume of training is preferable. When planning future endurance training studies in untrained subjects it should be taken into account that resting and exercise HR might reflect endurance changes during the first weeks of training only whereas VO2max remains responsive after several months.

MOTION CHARACTERISTICS ACCORDING TO PLAYING POSITION IN INTERNATIONAL MEN'S TEAM HANDBALL
Luig, P., Manchado Lopez, C., Pers, J., Perse, M., Kristan, M., Schander, I., Zimmermann, M., Henke, T., Platen, P.
Ruhr-University Bochum, Germany

Introduction:
Supported by fundamental rule changes the dynamics in international men's team handball have increased during the last decade. Recent data on running profiles of international top level players are not available. Therefore, this paper provides a large scale study into analysing motion characteristics of world class team handball players during international competition.

Methods:
About 170 players were monitored with cameras from the top of the sport halls during nine games of the 2007 Men's World Cup in Germany using a computer based match analysis system (SAGIT, University of Ljubljana, Slovenia). The system is validated for handball, basketball and squash. The recorded player trajectories delivered information about total distances covered and individual motion velocities of the players. By defining four categories of intensity (walking: 0 - 1.5 m/s, slow running: 1.6 - 4.0 m/s, fast running: 4.1 - 6.0 m/s, and sprinting: > 6 m/s), we were able to analyse a differentiated motion profile according to player position.

Results:
Mean time of player's action was 32.11 ± 15.34 min. Wing players (37.37 ± 2.37 min) and goalkeepers (37.11 ± 3.28 min) had significantly higher shares (p < 0.05) of playing time than backcourt players (29.16 ± 1.70 min) and pivot players (29.37 ± 2.70 min). Mean distance of the players. By defining four categories of intensity (walking: 0 - 1.5 m/s, slow running: 1.6 - 4.0 m/s, fast running: 4.1 - 6.0 m/s, and sprinting: > 6 m/s), we were able to analyse a differentiated motion profile according to player position.

Discussion:
The results clearly indicate position-specific differences in mean playing time, total distance covered and run intensity profiles in international top level men's handball. These differences should lead to position-specific training loads not only concerning tactical and technical training, but also concerning endurance and sprint training.

The study has been sponsored by the Bundesinstitut für Sportwissenschaft, Bonn: 01A1-071601/07.
INFLUENCE OF INSPIRATION, EXPIRATION AND APNOEA ON ISOMETRIC STRENGTH EXPRESSION AND EMG ACTIVITY DURING QUADRICEPS MAXIMAL VOLUNTARY CONTRACTIONS

Ippolito, D., Paoli, A., Marcolin, G., Pacelli, F., Fagan, R., Petrone, N.
University of Padova, Italy

In technical sport literature (1,2), several textbooks generally correlate respiratory phases with maximal strength expression. Even if there is a paucity of researches on this topic, textbooks underline that during apnoea athletes have the highest muscular strength value. The expiration phase has intermediate values. Aim of the study was to investigate the influence of Apnoea (A), Expiration (E) and Inspiration (I) on quadriceps EMG activity and strength expression during a Maximal Voluntary Contraction. 12 students were involved in the study. They were asked to perform 3 days a week 18 MVC divided in 3 sets as follow: 6 maximal isometric repetitions in Apnoea, 6 in inspiration and 6 in expiration. Each contraction was maintained for 3 seconds and was followed by 27 seconds rest. A recovery period of 4 minutes between sets was selected. After two weeks of training, each subject performed in 3 different days 18 quadriceps MVCs starting with sequence I, A, E the first day, sequence A, E, I the second day and sequence E, I, A the last day. Time duration of the isometric contractions and recovery time within and between sets were the same of the training period. Quadriceps isometric force was recorded by means of a load cell while surface EMG activity with a Muscle Lab® 4100e (Europe Ergotest, Boscossystem srl, Italy). Muscles analyzed were: vastus medialis (VM), vastus lateralis (VL) and rectus femoris (RF) of both legs. The means of rmsEMG of each repetition for each respiratory phase was calculated and then the mean of the means was obtained. The peak and average force obtained from the load cell were also compared in the three respiratory conditions. Analysis of variance showed that rmsEMG of VM and VL was significantly lower during Inspiration than during Expiration and Apnoea. Strength values showed no significant differences for mean and peak values.

Results indicate that exercises in like leg extension, where trunk muscles are not directly involved, different respiratory phases do not influence maximal isometric strength even if small but significant differences in rmsEMG were recorded. Further investigations on more complex exercises with muscles trunk involvement such as for example back squats are necessary to better explain the present data.

MOMENT-LENGTH PROPERTIES OF ATHLETE’S QUADRICEPS AND HAMSTRING MUSCLES AFTER ANGLE AND RANGE SPECIFIC EXERCISE

Ullrich, B., Brueggemann, G.P.
German Sport University Cologne, Germany

Muscular force and power production at specific joint angles are main determinants of athletic performance (1). Evidence exists that length-dependent force generation capacities of the M. quadriceps femoris (QF) and hamstring muscles (HAM) are not a constant property, but can adapt to functional requirements (2,3). However, a recent study failed to demonstrate that athletes with specific loading schemes of the QF show differences in the moment-knee angle relation of the QF (1). The purpose of this study was to investigate if different modes of angle and range specific strength training cause medio-lateral shifts in (i) isometric moment-knee angle relations and (ii) concentric power-load curves of QF and HAM.

N = 32 young athletes participated in a controlled nine weeks strength training period for QF and HAM. Week six of the training period was used for testing and no training was conducted. Subjects were randomly divided into three different training groups (G1-3): G1 performed knee angle specific cyclic (hold and relax) isometric training at long muscle-tendon unit (MTU) lengths. G2 conducted explosive concentric-eccentric training cycles that were restricted to the ascending part of the moment-knee angle relation of both muscles. G3 spent half of their training sessions with the isometric and half with the dynamic protocol. Isometric moment-and EMG-knee angle relations and power-load curves during maximal voluntary concentric actions with loads corresponding to 40%, 60% and 80% of 1 RPM were measured for QF and HAM at five different occasions: two times before start of the training period, after five and eight weeks of training and four weeks after the end of training. To investigate possible adaptations in length-dependent force generation capacities, moments, power values and EMG-data of each subject were normalized to the largest value produced at any knee joint position (% Max.). A second order polynomial curve fitting approach of the normalized moment and power values of each subject was used to determine the optimal knee joint angle for moment and power production.

G1-3 showed an increased potential in the ascending part of the moment-knee angle relation of QF in response to the training period. With only minor differences among G1-3, the optimal knee joint angle for QF-moment production was shifted about 6-9° in the direction of longer MTU lengths. The optimal knee joint angle for HAM-moment production was shifted about 3-4° in the direction of longer MTU lengths in G1 and G3, but remained rather constant in G2. For all testing loads, no medio-lateral shifts in knee angle-dependent power-load curves of QF and HAM were detected for any training group. These results provide evidence for training-induced medio-lateral shifts of isometric moment-joint angle relations, but question the transfer to explosive concentric muscle actions.

DERIVING THREE-DIMENSIONAL FORCES AND TORQUES IN SWIMMING

Sanders, R.
The University of Edinburgh, United Kingdom

Forces and torques changing the motion of humans performing sport skills can be transduced directly or can be derived from kinematic data. Measuring forces and torques acting on free swimmers directly, and in a manner that doesn’t affect the performance, is complicated by the swimming movement at the interface of two fluids, air and water, rather than being in contact with a solid supporting surface. The purpose of this presentation is to describe methods by which net three-dimensional (3D) forces and torques acting on swimmers can be derived from digitised position-time data and to provide examples of how those methods can yield original insights into swimming performance. Prior to the presentation of original and interesting findings the methods will be briefly outlined. These include the marking of swimmers to define a full segmented body model; obtaining body segment parameter data including segment masses and centre of mass locations relative to segment endpoints, and segment moments of inertia using the ‘Elliptical Zone’ method; calibrating the 3D space; simultaneous recording by multiple under water and above water cameras; transformation of the calibration and body markers digitised from each camera into 3D position-time data using the direct linear transformation (DLT) technique; and calculation of the net force components and torques about the three principal axes using a bespoke MATLAB program. The methods enable fresh insights into the mechanisms of propulsion in swimming, the contributions to body roll, and the influences of the forces and torques on the timing and rhythms of the swimmers’ linear and rotational motions.

COMPUTATIONAL FLUID DYNAMICS: A FUNDAMENTAL TOOL FOR SWIMMING RESEARCH

Silva, A., Marinho, D., Reis, V., Alves, F., Boas, J., Machado, L., Rouboa, A.
University of Tras-os-Montes And Alto douro, Portugal

Introduction
Swimming hydrodynamics has been studied since long with experimental tests and recently with numerical techniques using Computational Fluid Dynamics (CFD) models (e.g. Silva et al., 2008). The aim of this work was to present the already applied CFD techniques and to suggest new procedures that may be used by the research community in further studies under similar research topics.

Methods
The CFD methodology consists of a mathematical model applied to the fluid flow in a given domain that replaces the Navier-Stokes equations with discretized algebraic expressions and solved by iterative calculations. This domain consists of a grid or mesh of cells that simulate the fluid flow around physical structures. The boundary conditions were considered and implemented in the CFD commercial code Fluent®. In order to be able to simulate the fluid flow, models of the human body were used. Whole body human models were used to analyse the hydrodynamic drag while the hand and forearm models were used to analyse the upper arm propulsion during swimming.

Results
Regarding the studies involving the hydrodynamic drag it was found that: (i) in a drafting situation the drag of the back swimmer increased with the distance between swimmers and at a 0.50 m distance the drag of the back swimmer was around 50% of that of the front swimmer; (ii) during the gliding after the starts and turns, the position with the arms extended at the front presented lower values of hydrodynamic drag (60%) than the position with the arms along the trunk.

Regarding the upper arm propulsion, it was found that: (i) the hand/forearm drag was the coefficient that accounts more for propulsion; (ii) the coefficient of lift seemed to play a residual influence in the generation of propulsive force by the hand/forearm segment at angles of pitch of 0º and 90º, but it is important with an angle of pitch of 45º; (iii) under the accelerated flow conditions the hand/forearm models presented higher values of drag and lift coefficients than under the steady flow conditions.

Conclusion
The recent evidence suggests that the CFD technique can be considered an interesting new approach for hydrodynamic forces calculation in swimming, providing valuable considerations for defining new swimming techniques and other flow fields.

LACTATE CHARACTERISTICS IN CYCLISTS OF DIFFERENT AGE AFTER MAXIMAL CYCLING EFFORT

Zinner, C., Wahl, P., Frese, S., de Marées, M., Haegel, M., Bloch, W., Mester, J.
German Sport University Cologne, Germany

Introduction
Several studies show that, in terms of maximal lactate concentration, children have a lower anaerobic capacity than adolescents and adults. The higher absolute maximal blood lactate values of youth and adults are taken to confirm this statement. Studies investigating athletes of different ages only compared maximal lactate values. In this study the time course of blood lactate after a maximal cycling test was measured, furthermore all subjects had a common training situation, so that they are highly comparable.

Methods
10 boys (13±0.9years) and 13 male adolescents (17.2±0.9years) participated in the study.
The subjects performed a 30 sec lasting maximal sprint test on a cycle ergometer. The cycle ergometer was adjusted to an isokinetic mode regulating the cadence to 120 rpm. The subjects were instructed to perform the test only in a sitting position on the ergometer.

Blood samples were taken pre, 0min, 1min, until the 10th min, every minute to determine lactate concentrations in whole blood. After the test, the subjects recovered ten minutes passive in a sedentary position, to keep lactate elimination as low as possible.

Results

The adolescent group had a significant higher mean Peak Power (PP) in the 30 sec trial than the boys (976.1±101.5 Watt [W] vs. 600.3±168.0 W). The relative PP (relPP) reached by the adolescents (14.0±4 W/kg) was also significantly higher compared with the boys (relPP 11.4±1.8 W/kg).

During the 30sec a mean power output of 445.4±104.0 W was reached by the boys and 697.4±62.6 W by the adolescents. The relative mean power reached by the adolescents was 10.0±0.7 W/kg bodyweight and the boys reached 8.5±1.2 W/kg bodyweight.

The adolescent group reached a significant higher peak lactate level of 11.5±1.5 mmol/l in the 6th minute of recovery. The boys reached their peak lactate level of 9.4±1.0 mmol/l in the 4th minute. In contrast to the absolute lactate values, rel. lactate values were significantly higher for the boys. The values were 0.18±0.02 mmol/l/kg for the boys and 0.16±0.02 mmol/l/kg for the adolescents.

Discussion

Adolescents reached higher absolute lactate values, but related to the bodyweight, boys even showed significant higher lactate values, which might be hint for similar anaerobic energy production.

Comparing the PP of the two groups, the adolescents achieved a significantly higher meanPP, a significantly higher relPP and a significantly higher mean power output over the 30sec than the boys. This is likely due to the more limited ability of younger athletes to recruit and use higher-hierarchy motor units.

IS-PM06 ACSM Exchange Symposium. Clinical sports medicine - pre-participation screening

CURRENT STATUS OF THE PRE-PARTICIPATION EVALUATION IN THE USA

Dexter, W.

Maine Medical Center, United States

This talk (American College of Sports Medicine Exchange Lecture) will review the current status and trends in the pre-participation evaluation of athletes in the USA. The most recent changes in the Pre-participation Evaluation Monograph (fourth edition in press) will be discussed including the controversy surrounding decisions regarding the use of routine cardiovascular tests in screening.

PREPARTICIPATION EXAMINATION: A NEED FOR UNIFORMITY

Meeusen, R.

Vrije Universiteit Brussel, Belgium

The preparticipation physical exam (PPE) is a very important aspect for the care and safety of active and athletic individuals. Objectives of the evaluation include the discovery of conditions that may be life-threatening or disabling, that may limit participation, or that predispose to injury. The exam is not designed to exclude individuals from participation, but rather to assist athletes in safe participation. The preparticipation examination includes taking a proper history, performing the physical examination, and ordering appropriate laboratory tests. Athletes with medical illnesses can be directed to the sports activities that are best and safest for them. Although the preparticipation exam should not substitute for the individual’s regular routine health care, it is often the only exposure many of athletes have to a physician, and therefore offers a unique opportunity for health care evaluation and screening.

One can question if there is available evidence establishing the validity of the preparticipation evaluation as a method for screening health risk prior to participation in exercise and sport. Specific emphasis will be placed on reviewing original research evaluating methods to screen participants for risk of sudden cardiovascular death. The majority of the literature on the PPE consists of type III evidence-case-based opinion papers and position papers from respected authors and sports medicine societies and reports of expert committees. The format of the PPE is not always standardized and does not consistently address the recommendations for cardiovascular screening history and physical exams. A variety of health care professionals, some without proper training, administer the PPE.

A PPE is required by most sport organizations, but research as to its effectiveness is very limited. PPEs have been mandatory in Italy for many years, and we can draw on some of the data recorded over this time. Otherwise, very few studies have been performed on the PPE process. The research available indicates that the PPE is not implemented adequately or uniformly. An opportunity exists to create a standardized, validated PPE that meets medical standards for quality and provides sensitive, specific screening of potential participants in sport and exercise.
PERFORMANCE TRENDS AND PACING IN ELITE TRIATHLON

Vleck, V., Burgi, A.
University of Westminster, Trainerbildung Swiss Olympic, United Kingdom

This presentation first provides an overview of the evolution of performance in Elite Triathlon by comparing the relationships between overall performance times in each discipline, finishing position, and world ranking, over the consecutive ITU World Cup races within each of the qualification cycles for the Sydney 2000, Athens 2004 (Vleck, Grubb and Bentley, 2002) and Beijing 2008 Olympic Games Triathlons. The trends in pacing of the top vs. bottom placed finishers within the swimming, cycling and running sections of a specified ITU World Cup triathlon (Lausanne, Switzerland), for which the race course (Vleck et al., 2006) remained identical over consecutive years within the period 2001-2004, are then described.

The extent to which the relationships between pacing and performance in elite triathlon are further influenced by 'field composition' (Vleck et al., 2001-2004) are then described. An examination of the extent to which the above relationships may be influenced by or affect the 'performance power' of the athletes who are involved, both for the above ITU cup event location and the Beijing course, is then presented.

Finally, the above results are placed into context with the current state of knowledge (Millet et al., 2007) as regards what constitutes 'competitively significant performance' (Hopkins and Paton, 1999), and the mechanisms of fatigue (Abbiss and Laursen, 2005) in, Elite triathlon. Selected areas where additional research appears to be needed are identified.

TRAINING AND COMPETING IN TRIATHLON: WHAT CAN SCIENTISTS TELL COACHES?

Millet, G., Libicz, S., Girard, O., Roels, B.
ASPIRE, Academy for Sports Excellence, Doha, Qatar

The relationship between the scientific investigation and the evolution of the sport of triathlon have be reciprocally influenced. Scientific areas are related to changes in sporting rules, whereas science can use this sport as a model for general investigations (e.g. cardiac function, hypertratema, cross-training, underperformance syndrome) or as a specific area per se (e.g. wetsuit, drafting, transitions, pacing) where scientists can generate analyses of specific use for coaches and athletes (Millet et al 2007) First, by comparing physiological variables as maximal oxygen consumption (VO2max), anaerobic threshold, VO2 kinetics, heart rate, economy or delta efficiency measured in cycling and running in triathletes, runners or cyclists, scientists can identify the effects of exercise modality on the underlying mechanisms (e.g. ventilatory responses, blood flow, muscle oxidative capacity, peripheral innervations, neuromuscular fatigue) of adaptation (Millet et al 2008). Most of these information are still missing in swimming. Second, by quantifying training loads and investigating the cross-training effects between swimming, cycling and running (Millet et al 2002), scientists can help coaches to better design the overall content of their training program. Thirdly, by suggesting innovative methods of intermittent or interval-training based on the individual characteristics of the triathletes (e.g. VO2 kinetics), scientists give tools to coaches for optimizing their sessions in the three sports (Millet et al 2003). Fourthly, by analyzing the effects of swimming or cycling modalities on subsequent physiological/performance responses, scientists help to better design brick-training sessions specific to triathlon (Bentley et al 2007). Fifthly, by designing specific testing protocols to assess specific physiological profiles in triathletes, scientists provide relevant information to coaches on the changes in physiological characteristics of their athletes and therefore in the efficiency on their training program (Millet and Bentley 2004). Sixthly, by analyzing the responses (speed, power output..) during elite competitions, scientists help coaches to better design sessions, especially during the final preparation phase for a given competition (Vleck et al 2007).

To conclude, scientists can support coaches in better measuring, analyzing, and prescribing/individualizing/optimizing training content. However, the concept of scientific training is a misconception since the coach has to integrate parameters that are much more complex and beyond the scientific analysis.

STANDARDISED PHYSIOLOGICAL TESTING IN ELITE TRIATHLON: MAJOR CONCERNS AND COMMONLY USED METHODOLOGIES

Green, D.
Australian Olympic Institute of Sport, Australia; University of Queensland, Australia

Elite Olympic Distance (OD) triathlon consists of a 1.5km swim, 40km cycle and 10km run performed in sequential order. Elite triathletes will complete a typical OD triathlon in 100-130 minutes. Due to the nature of OD triathlon, the event is predominantly suited to aerobically gifted athletes, highly trained in all 3 disciplines and the physiological tests used in OD triathlon are a reflection of this. Any sporting performance is the outcome of an extremely complex interaction of multiple physiological systems which may be influenced by nutritional status, cognitive ability, motivation, aerobic fitness and anaerobic reserved. In comparison to a performance trial, standardised physiological tests aim to quantify the underlying change in ideally one, or more usually, several aspects of an athlete's physiology. A well-developed test will provide athletes and coaches with information of practical
significant, assisting in training prescription and detailing an athlete's progression, irrespective of training-induced fatigue, life stresses, etc. Similar to all scientific methods, standardised physiological testing in elite sport is susceptible to two major pitfalls: validity and typical error of measurement (TE). It is vital these concepts are considered and understood.

Validity can be described as how well a test predicts, describes or explains the variable you are trying to measure. Validity is the most important consideration when developing or utilising a test protocol. The TE is the intra-individual variability and allows quantification of the reliability of a measurement, which includes both biological and technical variation. TE provides information on the 'noise' of a test and, for interpretation, it is imperative that researchers consider the magnitude of their 'signal' in relation to the 'noise'.

All testing procedures should be clearly explained, replicated carefully and adhere to strict standards for environmental conditions, and equipment selection, calibration and maintenance.

The most commonly used physiological tests for elite triathlon are incremental tests, designed to investigate an athlete's physiological capability at a range of workloads. These tests can be conducted exclusively over submaximal workloads, or extended until volitional exhaustion. Elite triathlon performance has been shown to be highly correlated with both maximal and submaximal laboratory measures (2). At a minimum, most testing procedures will monitor heart rate, [blood lactate], and a subjective rating of exertion at the conclusion of each workload. Cycling and running protocols often measure the metabolic cost of each workload by monitoring O2 consumption and CO2 production.

Refinement of physiological tests will allow greater differentiation of the components of each major physiological system and mechanisms responsible for detected changes. References:

OP-HF04 Health and Fitness 4 - Disease

PEAK FORCE IN FAMILIAL AMILIOIDOTIC POLINEUROPATHY

Tomás, M., Santa-Clara, H., Monteiro, E., Cabri, J., Freire, A., Barroso, E.
Faculty of Human Kinetics, Lisbon Higher School of Health Technology, Portugal

Introduction. Familial Amyloidotic Polineuropathy (FAP) is a neurodegenerative disease related with systemic deposition of amyloid fibres mainly at the level of the peripheral nervous system. Clinically, the disease is characterized by an autonomous sensitive-motor neuropathy, beginning nearly always in foot, and subsequently involving the hands. Until now, the unique treatment for FAP disease is a liver transplant with aggressive medication to muscle metabolism and force production. To our knowledge, there are no quantitative characterizations of peak force levels in these patients or comparisons with healthy people. This knowledge will be extremely important to check the clinical and functional evolution of this disease.

Purpose. The purpose of this study was to compare the levels of hand grip strength (peak force) in FAP patients with (FAPT) or without (FAPNT) liver transplant and in a healthy group (HG).

Methods and Material. One hundred and one subjects where assigned to 3 groups: 57 (35 male, 22 female) patients FAPT (age, 34.9+/−8.2 years); 23 (9 male, 14 female) patients FAPNT (age, 34.2+/−8.3 years); and 21 (9 male, 12 female) HG (age, 33.6+/−8.4 years). Peak force levels in these patients or comparisons with healthy people. This knowledge will be extremely important to check the clinical and functional evolution of this disease.

Results. When comparing the 3 groups, no differences in age were found. However, significant differences (p<0.05), were found between groups, FAPT, FAPNT and HG for BMI (21.1+/−3.5, 22.9+/−5.4, 23.9+/−2.7 respectively), peak force on right hand (29.5+/−11.3, 31.2+/−13, 42.7+/−12.8 kg respectively) and left hand (28.2+/−11.5, 28.3+/−11.7, 37.9+/−11.7 kg respectively), and in classification norms according ACSM (3.8+/−0.7, 3.6+/−0.9, 2.3+/−1.3 respectively). Negative correlations between age and peak force were found in both hands for FAPNT (r=-0.513 p<0.05) and FAPT (r=-0.433 P<0.05), but not for the HG. A positive correlation between BMI and peak force in both hands for group FAPNT (r=0.643 p<0.05) was observed, but not in FAPT and HG. Furthermore, a positive correlation between age and BMI for FAPT group (r=0.270 p<0.05) was found, but not FAPNT or HG. When comparing peak forces between males and females in each group, significant higher values were observed (p<0.05) in males, but these differences seem to disappear in the grip strength norms according ACSM.

Conclusions. According our results and as expected, the FAP patients had lower values for peak force than healthy subjects, and consequently a worse classification in ACSM norms. For FAP patients it seems also that grip strength is more affected by age and BMI than for the HG. These results suggest also improvements in strength after liver transplantation.

ASSESSMENT IN PHYSICAL FUNCTIONAL FITNESS IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Pereira, A., Santa-Clara, H., Pereira, E., Simões, S., Carrão, L., Baptista, F., Pereira, C., Remédios, I., Cabri, J.
Faculty of Human Kinetics, Garcia de Orta Hospital, Portugal

Introduction. Chronic Obstructive Pulmonary Disease (COPD) is a chronic lung disease characterized by a progressive airflow limitation that is not fully reversible, and by an abnormal chronic inflammatory response of the airways. The main symptoms are dyspnea and impaired exercise capacity, which lead to progressive disability, poor health status and clinically relevant systemic effects at skeletal muscle, cardiovascular, neurologic, psychological level and endocrine system dysfunction. This pathology is being recognized a major and growing health problem worldwide, affecting particularly people over 60 years old.

Objectives. The purpose of this study was to identify differences in physical status and exercise capacity, between healthy subjects and COPD patients in the afore mentioned segment of age. Methods and Material. Forty-seven men with moderate COPD (FEV1 49.±±10.2%), age 66±4 yrs, weight, 73.9±11 kg, height, 168±6.7 cm, constituted the COPD group (COPD) and 110 healthy subjects (healthy group HG) age, 67.7±4 yrs; weight, 77.9±12.4 kg, height, 167,0±6,4 cm, were included. The physical parameters assessed were strength, aerobic
endurance, flexibility and agility/balance, by the Furlerton’s functional fitness tests. For upper body strength maximal amount of weighted arm curls was measured, for lower body strength the maximal amount of chair-ups were registered. Aerobic endurance was measured as the maximal distance covered in 6 minutes (6-min walk test). Upper body flexibility was assessed by back-scratch and lower body flexibility was assessed by sit-and-reach test. For testing agility/balance, an 8-foot up-and-go test was used.

Results. The values of the functional fitness test were significantly different (p<0.05) between COPDG and HG groups for the following variables: body mass index, 23.9±3 vs 27.7±4.1 kg/m2, 30-second stool chair times, arm curl 14.6±2.9 vs 18.8±4.9 time, 6-minute walk 502.9±70 vs. 594.4±92.4 m, 8-foot up-and-go 4.5±0.6 vs. 5.1±1 sec, chair sit-and-reach 0.79±1.02 vs. -8.1±10.9 cm respectively and no differences were observed for the back scratch test (DPOCG, -9.1±10.4 cm and HG, -12.0±11.9 cm).

Conclusions. COPD patients have lower physical functional ability than healthy subjects, which may promote a declining cycle including physical inactivity, impairment dyspnea and deconditioning, leading to disease progression, and, consequently to disability, poor health-related quality of life and premature mortality.

LEVELS, PATTERNS AND DETERMINANTS OF PHYSICAL ACTIVITY IN CHILDREN AND ADOLESCENTS WITH CONGENITAL HEART DISEASE

Coelho, E., Santa-Clara, H.
Faculty of Human Kinetics, Portugal

Children and the adolescents are usually seen as the healthiest elements of the population. Their health needs are usually preventive in character. However, for a certain segment of the youth population reality proves to be different. Children and adolescents with congenital heart disease (CHD) are many times kept from engaging in physical activity (PA) as a way to avoid complications. Consequently, they present an added risk of developing other health problems associated with a sedentary lifestyle. The aim of the present study was to evaluate the levels and determinants of PA in children and adolescents with congenital heart disease. Sixty-three children and adolescents with diagnosed clinical CHD participated in this study, 36 boys and 25 girls from the ages of 6 to 17 (age, 12.3±3.0 years), divided in two categories of complexity of CHD (46% mild CHD and 54% complex CHD). The data was collected by a validated questionnaire of AF -Activitygram and an interview with a closed script to evaluate the barriers and beliefs associated with doing PA. Only 2 (3.2%) subjects obtained values that respect international recommendations for doing PA. It was also verified that about 85% of the day time assessed were spent in situations of inactivity. Of the all subjects, 87% engaged in PA daily, 65% practiced aerobic activity, 6% engaged in exercises of muscular strength and none engaged in exercises of flexibility. Boys and girls showed identical levels of PA. Differences were not detected amongst both categories of complexity of CHD. Finally, negative associations were shown between the time spent in PA and the behavioural factors (rho=-0.395, p<0.01), the emotional and the cognitive psychological factors (rho=-0.383, p<0.01), and the biological and demographic factors (rho=-0.281, p<0.05). Positive associations were found between physical education classes in school and the time spent in PA (rho=0.555, p<0.001). Children and adolescents with CHD in this study show very low levels of PA from moderate to vigorous intensity. The behavioural factors seem to be the barrier that most influences the PA levels. Physical education classes in school can be a way for these children and adolescents to do more moderate and vigorous physical activity.

EFFECTS OF DIET AND EXERCISE ON THE BODY COMPOSITION, RESTING METABOLIC RATE AND EXERCISE CAPACITY OF PATIENTS WITH SEVERE MENTAL ILLNESS

Giannopoulou, I., Skouroliakou, M., Kostara, C., Koutri, K., Danou, K.
University of Strathclyde; Harokopio University; Iaso Hospital, Greece

Weight gain is an established side effect of atypical antipsychotics in patients with severe mental illness (SMI). Previous studies have shown positive effects of lifestyle interventions of diet and exercise in weight loss in this population. The purpose of this study was to investigate the effects of a 3-month nutrition and exercise intervention on the body composition, resting metabolic rate and exercise capacity of SMI patients in Greece.

Forty-seven (females: N=34, males: N=13) obese patients diagnosed with SMI (age: 41.51±1.8 years; body mass: 91.6±18.6 kg; body mass index: 33.4±5.6 kg/m2; mean±SD) volunteered to participate in the study. The duration of the study was 3 months and patients had to attend nutritional and exercise counselling sessions every 15 days. Prior to the start of the study patients’ body weight, body composition (Bodpod, Life Measurement Inc, CA) and resting metabolic rate (IRMR, Cosmed, Italy) were assessed. Patients also participated in a sub-maximal exercise stress test in order to assess their maximal oxygen consumption (VO2max) (Cosmed, Italy). At the end of the study the same experimental measurements were performed to assess differences in body composition, RMR and VO2max.

Significant improvements were found in the body weight (l-5.3±0.7 kg, P<0.01), fat mass (l-5.3±0.1 kg, P<0.01) and RMR (l+244.4±39.2 kcal, P<0.01) of the patients in the 3-month intervention period. Exercise capacity was also found to be increased as a result of the intervention from 26.9±5.5 ml/kg/min to 30.4±5.3 ml/kg/min (P<0.01). The changes in VO2max were correlated to the changes in body weight (r=0.33, p<0.05) and fat mass (r=0.30, p<0.05) of the patients. When dividing the patients by gender, no differences among genders were found in the responses to the intervention in the body weight, body composition and RMR. However, significant gender differences were found in the improvements in exercise capacity, with females significantly improving VO2max by 15% (pre: 25.27±4.73 to post: 29.60±5.41 ml/kg/min, P<0.01) of the patients in the 3-month intervention period. Exercise capacity was also found to be increased as a result of the intervention from 26.9±5.5 ml/kg/min to 30.4±5.3 ml/kg/min (P<0.01).

In conclusion, SMI patients respond favourably to lifestyle interventions of diet and exercise as demonstrated by improvements in their body weight, body composition, RMR and exercise capacity. More investigation is needed to examine whether gender differences exist in the exercise capacity of this population.

FREQUENCY OF CYCLE TRIPS PER WEEK AND BICYCLING DAYS PER YEAR

Schantz, P., Stigell, E.
The Åstrand Laboratory, Sweden

Purpose.
Values on frequency of bicycle trips are used in cost-benefit analyses within the transport sector and in a health economic assessment tool for cycling recently developed by WHO Europe. Such data should preferably be assessed in different environmental settings, e.g. in relation to climate and hours of light over the year. The aim of this study was therefore to illuminate these issues in commuters bicycling in the metropolitan area of Stockholm, Sweden.

Methods
The subjects cycled to work or study place, lived in the County of Stockholm and volunteered after being contacted through advertisements in morning newspapers. Questionnaires were sent to all of them in September 2005. The bicyclists were divided into single mode bicyclists, n = 1158, and those that sometimes cycled, sometimes walked to work (dual mode bicyclists, n = 535). They responded to questions on average number of trips per week for each month as well as their normal trip pattern in relation to proportion of return journeys per day.

Results
The table below presents median number of bicycle commuting trips per week during different months for single mode (sm) and dual mode (dm) bicyclists.

Mean value of median numbers of trips during the year was 4.54 per week for the single mode bicyclists and 4.75 for the dual mode bicyclists. Given the fact that the normal trip pattern was 97% return journeys on the same day for both groups, the number of commuting cycling days per year was estimated to be 122 for single mode bicyclists and 127 for dual mode bicyclists.

Conclusion
Physically active commuting appears to be associated with a high number of physically active days per year. The frequency of bicycle trips for commuting can, however, vary substantially over the year. The consequence of this is that using spot data for this variable can mislead and create substantial over- or underestimations of the level of physical activity connected to bicycle commuting over the year. The variations in number of bicycle trips over the year point to the value of more studies of these aspects in different environmental settings.

FREE-RUNNING CIRCADIAN RHYTHM OF ISOMETRIC AND ISOKINETIC CONCENTRIC FORCE IN BLIND ATHLETES

Squarcini, C., Pires, M., Benedito-Silva, A., Cornelissen-Guillaume, G., Lopes, C., Matarazzo, C., Garcia, D., Peccin, S., Tufik, S., De Mello, M.

Federal University of Sao Paulo - UNIFESP, Brazil

Light is considered the main endogenous stimulus synchronizing circadian rhythms to 24 hours with the environment through body temperature, hormonal secretion and variables related to physical performance, particularly muscular strength. In light absence, as in the case of totally blind individuals, the circadian rhythms of body temperature and hormonal secretion tend to be free-run, with endogenous periods (tau) usually exceeding 24 hours in humans. However, the circadian rhythm of muscular strength in this population is not known. The present study aimed at analyzing the circadian rhythms of isometric and isokinetic concentric muscular contraction strength in totally blind athletes with free-running circadian rhythms. Data from participants six blind athletes with free-running rhythms for melatonin (or cortisol) secretion were collected for isometric force (handgrip and back flexion-extension), and isokinetic concentric knee flexion (at speeds 60º/s and 90º/s), and body temperature during three sessions at one- and two-week intervals. In each session, data were collected at 6 different times of day, with a minimum of 8-hour apart. Statistical analysis employed the cosinor method to determine each subject’s individual acrophases. Independently of circadian rhythm detection by cosinor analysis, acrophases were converted to lags from initial acrophase (first session). Relative acrophases were pooled across all 6 subjects and linear regression as a function of days from start, the slope as a gauge of average daily shift. The results show that regardless of muscle group or contraction speed, the endogenous period of force and body temperature was statically significantly longer than 24 hours, suggesting free-running of strength in these athletes. Like as example: endogenous period (tau) of body temperature estimated as 24.8 hours, with 95% confidence limits of ±0.7 hour, for back strength tau = 24.7 hours (95%CI = ±0.6 hour) and for dominant extension of knee in 90º/s tau = 24.9 hours (95%CI = ±0.8 hour). It is concluded that the muscular strength rhythm is generated by an internal mechanism, since in absence of light perception the organism expresses a circadian rhythm. As far as we know, this is the first research to show the circadian rhythm of sports-related variable in blind individuals. Therefore, trainers and health professionals working with blind people should be aware of the importance of including a circadian rhythm evaluation in their routines.

OP-PM09 Physiology 9 - Cardiovascular

RELATIONSHIP BETWEEN MEASURES OF FITNESS, PHYSICAL ACTIVITY, BODY COMPOSITION AND VASCULAR FUNCTION IN CHILDREN

Hopkins, N., Stratton, G., Tinken, T., McWhannell, N., Ridgers, N., Graves, L., Cable, N., Green, D.

Liverpool John Moores University, United Kingdom

Background. Flow mediated dilatation (FMD), the increase in artery diameter which occurs following a brief period of distal limb ischaemia as a consequence of increased luminal blood flow and wall shear stress, is now established as a valid index of vascular endothelial function. Endothelial dysfunction has been proposed as an early event in atherosclerosis, the health of the endothelium therefore represents a barometer for cardiovascular risk. Endothelial dysfunction is evident in children exposed to risk factor such as hypercholesterolaemia, smoking and homocysteinaemia. It is also evident in obese children, exercise training reverses endothelial function in such subjects. The increased prevalence of obesity and type 2 diabetes in young people represents a future cardiovascular health time-bomb and effective prevention depends upon early detection and appropriate management of specific risk factors. Given that no studies have attempted to examine the complex relationship between physical activity, cardiorespiratory fitness, body composition and vascular function in children, the present study aimed to identify the predictors of artery health in children with impaired FMD.
HETEROGENEITY IN CONDUIT ARTERY FUNCTION IN HUMANS: IMPACT OF ARTERIAL SIZE

Thijssen, D., Dawson, E., Black, M., Hopman, M., Cable, N., Green, D.
Liverpool John Moores University, United Kingdom

Direct in vivo measurement of the function of arteries such as the brachial, radial, popliteal and femoral, has recently become a powerful method of predicting those at risk of future cardiovascular disease. Vascular adaptations to exercise training, which may decrease cardiovascular risk, can also be directly assessed by measuring changes in artery function. However, artery function measures may be dependent on the structure or size of the artery in question.

Purpose. Therefore, the aim of this study was to determine whether conduit artery size affects functional responses in humans.

Methods. We compared the magnitude, time-course and eliciting shear rate stimulus for flow-mediated dilatation (FMD) and glyceryl trinitrate (GTN) mediated dilation in 11 healthy men (33±6 yrs). Upper limb (brachial and radial) and lower limb (common and superficial femoral) FMD responses were simultaneously assessed, whilst popliteal responses were measured in the same subjects during a separate visit. GTN-mediated responses were similarly examined. Edge-detection and wall-tracking of high resolution 8-mode arterial ultrasound images, combined with synchronized Doppler waveform envelope analysis, was used to calculate conduit artery diameter, blood flow and shear rate continuously across the cardiac cycle.

Results. Baseline artery size correlated strongly and inversely with the FMD response (r=-0.56, p<0.001). Normalization of FMD responses for differences in eliciting shear rate did not abolish this relationship between artery function and size (r=-0.48, p=0.001), suggesting that differences between artery function responses were not due to size-related differences in shear rate. This was reinforced by a significant correlation between baseline artery size and responses to GTN, a shear rate-independent dilator (r=-0.75, p<0.001). Together with the observation that time to peak dilatation during the FMD strongly correlated with baseline artery size (r=0.62, p<0.001), these data confirm the impact of artery size on the magnitude and timing of functional responses and, furthermore, indicate that shear stress independent factors contribute to differences in vasodilatation between arteries of varying dimension.

Conclusion. We have therefore established a physiological tenet, that the size of arteries has a direct impact on their functional responses. This has implications for all studies that have previously assessed FMD as a surrogate marker of artery health in humans, where differences in baseline artery diameter within individuals (different arteries or after an intervention) or between groups were not taken into account.

CARDIAC AUTONOMIC REGULATION IN CORONARY ARTERY DISEASE WITH AND WITHOUT DIABETES

Kiviniemi, A., Hautala, A., Mäkikallio, T., Huikuri, H., Tulppo, M.
Verve Research, Finland

BACKGROUND: Cardiovascular autonomic regulation measured by 24-hour heart rate variability (HRV) is impaired in diabetic subjects compared to matched non-diabetic subjects. However, it is not known whether reduced HRV is predominantly associated to diabetes itself or to reduced exercise tolerance of diabetic patients. This case-control study assessed exercise tolerance as determinant of cardiac autonomic function among patients with diabetes and coronary artery disease (CAD) compared to their matched counterparts without diabetes.

METHODS: Consecutive series of CAD patients with a recent myocardial infarction (n=700) underwent Holter recording, symptom-limited exercise test by bicycle ergometer and echocardiography. All patients were under beta-blocking medication. Diabetic and non-diabetic patients were matched 1:3 in respect to gender, age, body mass index and left ventricular ejection fraction. Thereafter, the patients were matched 1:1 additionally according to exercise capacity. HRV indexes, such as standard deviation of R-R intervals (SDNN), very low- (VLF, 0.003-0.04 Hz), low- (LF, 0.04-0.15 Hz) and high-frequency (HF, 0.15-0.4 Hz) spectral components, were analyzed from Holter recordings.

Chronicotropic response to exercise was evaluated by heart rate (HR) reserve (= peak HR - resting HR). RESULTS: Initial matched population included 52 diabetic and 156 non-diabetic patients (176 males, 32 females, age: 63±9 years, body mass index: 27±3, ejection fraction: 47±7%). Compared to non-diabetic counterparts, diabetic patients had significantly lower exercise capacity (5.1±3 vs. 5.7±1.3 METs, p=0.006), SDNN (86±30 vs. 103±32 ms, p=0.001), VLF (6.3±0.7 vs. 6.7±0.8 ln ms2, p=0.010), LF (5.3±1.0 vs. 5.7±0.9 ln ms2, p=0.005) and HF reserve (53±19 vs. 67±20 bpm, p<0.001). When patients were matched in respect to exercise capacity (n=44 for both groups), no differences were observed in any HRV variable. HR reserve was still significantly lower in diabetic patients compared to non-diabetic patients (54±19 vs. 66±17 bpm, p=0.002).

CONCLUSION: Reduced 24-hour HRV is predominantly a result of impaired exercise capacity among the diabetic patients with CAD. Chronotropic incompetence seems to be specific feature of abnormal autonomic function in diabetic patients, which is not directly related to exercise performance.
Introduction.
In humans, heat stress leads to pronounced increases in cardiac output and heart rate (HR). Recently, a heat stress induced significant increase in ejection fraction (EF) was reported (Crandall et al 2008). Whilst these findings may indicate an increase in LV systolic function, EF is an imperfect measure of contractility. In order to further elaborate the influence of passive heating on LV function, the present study sought to evaluate the hypothesis that passive heat stress increases myocardial strain, rate and torsion.

Methods.
Six active male subjects (21±2yr) completed the study. Measurements were made at 4 different resting conditions: 1) Control (Tcore ~37°C, Tskn ~32°C), 2) skin hyperthermia (Tc ~37°C, Tsk ~36°C), 3) skin and core hyperthermia (Tc ~38°C, Tsk ~37°C), and 4) high skin and core hyperthermia (Tc ~39°C, Tsk ~38°C). Subjects were fully hydrated throughout the study. Echocardiographic images were acquired at each stage of heat stress. Two-dimensional images were analysed for EF, stroke volume (SV), LV circumferential, radial and longitudinal strain (Scirc, Srad and Slon) and strain rates (SRcirc, SRrad and SRlon). LV torsion was calculated as the net difference in degrees of rotation between the LV apex and base (Notomi 2005). End-diastolic volume (EDV) and mean arterial pressure (MAP) were measured as surrogates of preload and afterload, respectively. Heart rate (HR) was assessed throughout the trial using a three lead ECG. A repeated measures ANOVA was used to detect effects over time and paired student t-test was applied post-hoc to ascertain differences between conditions. Alpha was set at 0.05, Bonferroni adjustment was made for repeated comparisons.

Results.
EF increased between control and high core hyperthermia (61±4 vs. 76±7%, p<0.05). Whilst these findings may indicate an increase in LV systolic function, EF is an imperfect measure of contractility. In order to further elaborate the influence of passive heating on LV function, the present study sought to evaluate the hypothesis that passive heat stress increases myocardial strain, rate and torsion. Improvements in intrinsic systolic function may compensate for heat induced reductions in EDV.

THE EFFECT OF 60-HOUR SLEEP DEPRIVATION ON CARDIOVASCULAR REGULATION AND AEROBIC PERFORMANCE

Vaara, J., Kyröläinen, H., Koivu, M., Tulppo, M., Finni, T.
University of Jyväskylä, Finland

INTRODUCTION. Sleep deprivation (SD) is common in sustained military operations and in some sport events (VanHelder & Radomski 1989). This study examined the effect of 60-hour sleep deprivation on aerobic performance and cardiovascular regulation.

METHODS. Twenty healthy cadets (17 men, 3 women, age 26 ± 3 yrs) volunteered. During SD they performed military tasks related to tactics but their physical activity was restricted to minimum and they were constantly under observation for not falling asleep. They were not allowed to drink any caffeine containing liquids, but water and food could be consumed ad libitum. Cardiovascular regulation was assessed by measuring heart rate variability (HRV) in orthostatic test (5 min sitting, 3 min standing) each day in the morning and evening. Heart rate (HR, Polar Advantage), oxygen uptake (VO2) and ventilation (VE, Cosmed K4b2) were measured constantly during performance. Blood lactate (Lacta, Lactate pro) and rate of perceived exertion (RPE) were measured every two minutes. Also time to exhaustion was measured.

RESULTS. In sitting and standing positions HF, LF and RMSSD increased and HR decreased between the first and third day (P<0.05 for all). At submaximal work loads (100-250 W) HR, VO2 and VE decreased (P<0.05 for all). However, maximal values of HR, VO2, VE, RPE or time to exhaustion did not change after SD. Maximal Bla decreased after SD (P<0.05)

CONCLUSION. Sleep loss results in an increased vagal outflow, documented by increased vagally mediated heart rate variability indices and decreased heart rate. Maximal aerobic performance was not affected, but however, at submaximal exercise intensity levels the heart rate and respiratory parameters were decreased. The changes in cardiorespiratory parameters at submaximal exercise intensity levels and during orthostatic test may occur via altered function of circulatory and respiratory regulation centers at the central nervous system level.

EXERCISE TRAINING PROTECTS CARDIAC FUNCTION AND STRUCTURE IN ANIMALS SUBMITTED TO ACUTE PRESSURE OVERLOAD

Moreira-Gonçalves, D., Henriques-Coelho, T., Duarte, J., Leite-Moreira, A.
Faculty of Medicine University of Porto, Faculty of Sports University of Porto, Portugal

Emerging evidences indicate that exercise training provides significant protection to the myocardium against several deleterious insults such as ischemia, ischemia-reperfusion and cardiotoxicity. Less studied, is the eventual cardiac protection conferred by exercise to an
structural alterations, which seems to precede hemodynamic alteration, highlighting ventricular interaction. This study highlights that function was also improved. Although the observed disturbances in function and structure in LV of sedentary animals, RV only suffered increased LVPmax during the entire protocol (154.7± 26 vs 77.4±25.6 mmHg/s) and responded with a significant increase of LVdP/dtmax evaluated by time constant tau. Peak pressure (Pmax), peak rate of pressure elevation and fall (dP/dtmax and dP/dtmin) and relaxation rate evaluated by time constant tau were assessed. Papillary muscles were collected from both ventricles and prepared for transmission electron microscopy (TEM) analysis. The severity of tissue damage was scored (0-3) taking into account the amount of cardiomyocytes exhibiting intracellular edema and/or mitochondrial swelling.

Results are presented as mean±SD; p<0.05. There were no differences regarding RV function. Contrary to Sh, Tr were able to maintain an increased LVPmax during the entire protocol (154.7±26 vs 77.4±25.6 mmHg/s) and an impairment in time constant tau in Sh (15±3 vs 22±9 ms) with no changes in Tr (13±1 vs 13±3 ms). Regarding TEM, Sh presented significantly higher grades of intracellular edema and mitochondrial swelling in both ventricles in comparison to Tr (LV: 2.5±0.5 vs 1.3±0.7; RV: 2.1±0.6 vs 0.9±0.7).

Two hours of pressure overload by aortic banding enhanced systolic function in trained animals, in opposition to sham group. Diastolic function was also improved. Although the observed disturbances in function and structure in LV of sedentary animals, RV only suffered structural alterations, which seems to precede hemodynamic alteration, highlighting ventricular interaction. This study highlights that chronic exercise has advantages in RV and LV adaptation to a cardiac insult like an acute and sustained cardiac pressure overload.

THE EFFECT OF A HEAT EXTRACTION DEVICE ON RECOVERY AND PERFORMANCE IN HOT AND HUMID CONDITIONS

Hunter, K., Murphy, A., Coutts, A., Graham, K.
University of Technology, Sydney, Australia

Introduction.
In situations where physical performance is limited by elevations in core temperature, extraction of excess heat from the body core should enhance performance capacity [1]. The rapid thermal exchange device (RTX, AVACore Technologies, Ann Arbor, MI) aims to achieve this via the combined application of sub-atmospheric pressure and a heat sink to the palm of the hand [2]. However, the optimal operation and scope of RTX implementation during exercise and recovery are yet to be determined.

Methods.
Using a random crossover design, nine moderately trained male team sport athletes (24.8 ± 4.4 yrs, 78.4 ± 9.3 kg, VO2max = 43.2 ± 6.8 mL.kg-1.min-1) participated in two separate experimental trials on a cycle ergometer in a hot and humid environment chamber (33°C, 62% RH). Each trial consisted of a brief warm-up followed by 15 minutes cycling at 70% work max (Wmax) (Preload) before five minutes of passive recovery (Recovery 1). Subjects then completed a second 15 minute cycling bout at 70% Wmax (Steady State) followed by ten minutes of passive recovery (Recovery 2) and finally a ten minute Time-trial. During both Recovery 1 and Recovery 2 subjects used either the RTX device (15°C) or no intervention (CON). Tympanic temperature (TyT), mean skin temperature (Tsk), heart rate (HR), sweat rate, blood lactate ([BLa-]), rating of perceived exertion (RPE), thermal sensation (THS), thermal comfort (THC), work and power output were measured throughout both trials. Bonferroni adjusted paired t-tests were used to evaluate the effect of the RTX. Significance was set at p<0.05.

Results.
In the RTX trial there was a significant reduction in TyT following Recovery 2 compared to the CON trial (37.5 ± 0.3°C vs 37.7 ± 0.4°C). Additionally, HR was lower during both Recovery 1 (107 ± 5 bpm vs 114 ± 13 bpm) and Recovery 2 (115 ± 9 bpm vs 123 ± 13 bpm) and Tsk was lower following the Steady State (34.06 ± 0.51°C vs 36.26 ± 0.47°C) and Recovery 2 (34.07 ± 0.42°C vs 36.29 ± 0.42°C) in the RTX trial. There were no differences in sweat rate, [BLa-], RPE, THS or THC between trials. In the Time-trial subjects performed significantly more work (134.0 ± 9.6 kJ vs 126.8 ± 18.6 kJ) and had a greater mean power output (223.3 ± 16.0 W vs 211.3 ± 31.0 W) in the RTX trial compared to the CON trial.

Conclusion.
These results suggest that a heat sink temperature of 15°C in a vacuum facilitates a significant thermal gradient whilst simultaneously minimising reflex vasoconstriction in the palm. This enables sufficient palmar blood flow for effective heat transfer, minimising thermal strain during recovery. Potentially the RTX is an effective ergogenic aid for exercise performance in hot and humid conditions when used during recovery periods.

HEAT STRESS INCREASES LEG MUSCLE AND SKIN BLOOD FLOW IN RESTING AND EXERCISING HUMANS

Brunel University, United Kingdom

Introduction.
Heat stress increases cardiac output (Q) at rest and during exercise in humans largely to meet the augmented thermoregulatory demands of the skin circulation (González-Alonso et al. 2008). Whether heat stress causes muscle vasodilatation and thereby increases
muscle perfusion remains uncertain. This study tested the hypothesis that local leg and systemic hyperthermia increases leg muscle, leg skin and systemic perfusion at rest and during exercise.

Methods.
Leg and systemic hemodynamics, O2 transport and VO2 were measured at rest and during 6-min of one-legged knee-extensor exercise (23±3 W) in 7 active males (21±2 yr) in 4 conditions, in which participants' hydration status was maintained. 1) control (Tcore ~37°C, Tsmin ~33°C), 2) skin hyperthermia (Tc ~37°C, Ts ~36°C), 3) skin and mild core hyperthermia (Tc ~38°C, Tsk ~36°C), and 4) high skin and core hyperthermia (Tc ~39°C, Tsk ~37°C). Femoral artery blood flow (LBF; Doppler ultrasound), vastus lateralis skin blood flow (SkBF; laser Doppler flowmetry) and blood gas and haematological variables (ABL 825, Radiometer) were measured in each condition. Data were analysed using a one-way ANOVA with repeated measures and Tukey’s post hoc analysis with significance accepted at P<0.05. Data represent means±SEM.

Results.
At rest and during exercise, LBF and Q increased with each elevation in heat stress compared to control (peak delta LBF= 1.1±0.1 and 0.9±0.2 L/min from 0.5±0.1 and 2.4±0.2 L/min, respectively; peak delta Q= 4.0±0.2 and 3.1±0.3 L/min from 5.1±0.2 and 7.4±0.4 L/min, respectively). However, the increase in LBF and Q due to exercise (exercise hyperemia) was the same (~1.6 L/min) in all heat stress conditions. Correspondingly, SkBF initially increased with heat stress and skin and mild core hyperthermia (8.5±1.4-fold) but showed no additional elevation with high skin and core hyperthermia. The increased muscle perfusion accounted for the further increase in LBF. In addition, the increase in SkBF due to exercise was not different among conditions. Mean arterial and perfusion pressure declined, yet leg vascular conductance increased with heat stress, indicating that the increased leg perfusion was due to local vasodilatation. The elevation in leg muscle and skin temperature alone accounted for by >50% of the increase in LBF and SkBF with high skin and core hyperthermia. The elevated leg perfusion with each level of heat stress was accompanied by a parallel reduction in leg O2 extraction such as that leg VO2 remained unaltered either at rest or during exercise.

Conclusions.
These findings demonstrate that heat stress increases leg muscle and skin blood flow in resting and exercising humans. Further, the results suggest that increases in muscle tissue temperature per se might contribute to local muscle blood flow regulation and exercise hyperemia.

THERMOREGULATION AND PERFORMANCE IN NORMAL AND HIGH AMBIENT TEMPERATURE: NO EFFECT OF A SELECTIVE SEROTONERGIC REUPTAKE INHIBITOR

Roelands, B., Goekint, M., Heyman, E., Meeusen, R.
Vrije Universiteit Brussel, Belgium

Introduction
The central fatigue hypothesis is based on the assumption that the synthesis and metabolism of central monoamines, in particular serotonin (5-HT), dopamine (DA) and noradrenaline (NA), are involved in the development of fatigue (Meeusen, 2006). Acute DA/NA reuptake inhibition (bupropion) significantly improved time trial performance, hormonal responses to exercise and thermoregulation in the heat (30°C, Watson, 2005). A selective DA reuptake inhibitor had similar or even more pronounced effects on performance and core temperature in 30°C (Tcore, Roelands, 2008a). In contrast, acute NA reuptake inhibition decreased performance (Roelands, 2008b). Since the original central fatigue hypothesis states that fatigue during prolonged exercise could be due to a higher 5-HT activity, we examined the effects of acute administration of a selective 5-HT reuptake inhibitor (SSRI) on performance and thermoregulation.

Methods
Eleven healthy trained male cyclists completed four experimental trials (two in 18°C, two in 30°C) in a double blind-randomized crossover design. Subjects ingested either a placebo (PLAC; 2x10mg) or Citalopram (CITAL; 2x10mg) on the evening before and the morning of the trial. Subjects cycled for 60 min at 55%Wmax, immediately followed by a time trial (TT) to measure performance. Tcore, skin temperature, heart rate, blood pressure, sweat loss, RPE, thermal stress, blood lactate and hormonal data were recorded. The significance level was set at p<0.05.

Results
Acute SSRI did not change performance on the preloaded TT (18°C p=.518; 30°C p=.112). Tcore was identical between PLAC and CITAL during exercise in each temperature setting. During recovery in 30°C Tcore was significantly lower in the CITAL trial (p<.012). In 30°C heart rate was significantly lower after exercise in CITAL (p=0.13). In 18°C there was no difference in heart rate. No differences were observed for skin temperature, RPE and thermal stress. CITAL significantly increased CORT values at rest (p=.016), after the TT (p=.006) and after 15 minutes of recovery (p=.041).

Discussion/Conclusion
The lack of effect on performance is in accordance with previous studies performed with SSRI (Meeusen, 1997, Strachan, 2004, Strachan, 2005). The effects of SSRI on core temperature are inconsistent and probably depend on which receptors are activated (Strachan, 2004). Our results suggest that, in these specific circumstances, the 5-HT neurotransmitter system has no direct influence on performance and thermoregulation.

SHORT DURATION NECK COOLING DOES NOT IMPROVE 15-MIN TREADMILL TIME-TRIAL PERFORMANCE IN THE HEAT

Tyler, C., Sunderland, C.
Nottingham Trent University, United Kingdom

INTRODUCTION: Running performance is impaired in hot, compared to moderate, conditions (Tyler & Sunderland, 2008) and it has been proposed that a high brain temperature may be the reason for this (Capuata et al., 1986). Cooling the neck might be an effective way of lowering brain temperature by reducing the temperature of the carotid blood (Zhu, 2000) and it seems prudent to suggest that this may attenuate the performance impairment observed. Cooling the neck during exercise in the heat has been shown to elicit potentially beneficial thermo-regulatory and cardiovascular changes (Bulbulian et al., 1999; Gordon et al., 1990) however the effect of cooling the neck on exercise performance has not been investigated. AIM: To investigate the effect of cooling the neck during 15-minute treadmill running on performance in high ambient temperatures. METHODS: Eight, familiarised, trained males completed two 20-min trials in the heat (30.5 ± 0.1°C, 53 ± 2% rh) on a motorised treadmill with (CC) or without (NC) a neck-cooling collar. The trial consisted of a 5-min warm-up at 9km.hr-1 followed by a 15-min self-paced time-trial. Distance covered, heart rate, rectal temperature, neck temperature, rating of perceived exertion, thermal sensation and water consumption were recorded throughout. Nude body mass was recorded pre- and post-exercise. Paired t-tests and one-way and two-way ANOVA with repeated measures were used with Tukey’s HSD post hoc tests were appropriate. Significance was accepted as P < 0.05. RESULTS: There was no significant difference in the distances covered during the 15-minute TT with the application of the cooling collar (CC: 3.239 ± 267m; NC: 3.180 ± 271m; P = 0.351). Mean neck temperature was cooler throughout the trial with the collar (mean difference -11.05 ± 1.08°C; P = 0.000). Subjects commenced the time-trial feeling significantly cooler (P = 0.006) however there were no differences during the time-trial. There were no differences for heart rate (P = 0.305; rectal temperature (P = 0.665); RPE (P = 0.925) or sweat loss (P = 0.756) between trials. The cooling collar significantly reduced voluntary water intake (P = 0.033). CONCLUSION: Time-trial performance in the heat was not significantly improved by the short-term application of a cooling collar despite a significant reduction in the mean neck temperature throughout the trial. The effectiveness of such a cooling intervention appears to be dependent upon the magnitude of the thermal stress experienced during exercise (Nunneley et al., 1971) and so it is likely that the 20-min bout provided an insufficient thermal stress to benefit from the cooling intervention.

Effects of Different Water Temperature on Reactivation in Cardiac Parasympathetic Nervous System during Supine Floating After Exercise

Nishimura, K., Korniyama, M., Yoshioka, A., Seki, K., Onodera, S.
Graduate School, Kawasaki University of Medical Welfare, Japan

Introduction: In the water, humans have different physical responses compared to land due to influences of physical characteristics of water such as water temperature, water pressure, buoyancy and viscosity. We suggested that the supine floating after exercise could increase the cardiac parasympathetic nervous system activity which was inhabited by exercise. During immersion at rest, humans made different responses by water temperature. We hypothesized that influences of different water temperature made different responses not only at rest, but also during recovery after exercise. The purpose of this study was to determine the effects of different water temperature on reactivation cardiac parasympathetic nervous system during supine floating after exercise. Methods: Six healthy Japanese males volunteered for this study. Their mean age, height, body weight, %body fat and maximum oxygen uptake were 21.3 ± 2.1yeras (mean ± SD), 169.3 ± 2.9cm, 66.6 ± 10.1kg, 17.1 ± 2.1%, 46.0 ± 8.2ml/kg/min., respectively. All subjects signed an informed consent form prior to participation in this study. Subjects maintained their supine position for 30 minutes on bed or floating, after exercise for 15 minutes. Water temperature of the supine floating was 25 (WT-25), 30 (WT-30) and 35 (WT-35) degrees Celsius. Exercise intensity was 50%VO2max. Measurement items were heart rate, cardiac autonomic nervous system activity. Cardiac autonomic nervous system activity was calculated using Maximum Entropy Calculation Methodology (MemmCalc). The cardiac parasympathetic nervous system activity was estimated by two indexes. One is log HF, the high frequency domain (HF; 0.15-0.40Hz) was transformed into logarithmic values to obtain a statistically normal distribution. Another is the slope in PNS. We calculated regression line in appearance time and peak of HF. The slope of regression line defines reactivation in cardiac parasympathetic nervous system (Slope in PNS). Results and Discussion: Heart rate increased about 160 bpm. Heart rate and log HF of post exercise were no significant differences under the four conditions. During the recovery process, log HF was significantly increased under the WT-25 and WT-30, as compared to the WT-35 and C-condition (p< 0.05, respectively). Peak of HF in WT-25 (166.8 ± 152.5%) was significantly higher than WT-35 (75.6 ± 94.7%) and C-condition (33.2 ± 38.8%) (p< 0.05, respectively). The Slope in PNS of WT-25 (167.4 ± 153.6) was significantly higher than WT-35 (75.7 ± 95.0) and C-condition (33.2 ± 38.8) (p< 0.05, respectively). These data suggest that it is significant differences on reactivation in cardiac parasympathetic nervous system to different water temperature during supine floating after exercise. And, reactivation in cardiac parasympathetic nervous system was significantly increased, when water temperature was lower than body temperature.

Functional Architecture of Human Thermoregulation under Increasing Levels of Exercise in the Heat

Flouris, A., Cheung, S.
Centre for Research and Technology – Thessaly, Greece

Thermoregulatory investigations have been an integral part of physiological research generating voluminous evidence that have illuminated latent physiological mechanisms at all levels of biological organization as early as in the 18th and 19th century (Richet, 1885, Ott, 1887, Greene, 1913). Yet, our knowledge remains limited on topics as critical as the functional architecture of human thermoregulation. The most prominent hypothesis proposed to date recognizes a thermal set point which the body’s control systems attempt to maintain, but it remains unknown whether the identification, monitoring, and maintenance of this set point are based on temperature or heat. In this experiment we examined whether the human body regulates core temperature or heat loss by assessing changes in these variables under environmental heat exposure and increasing levels of heat production through exercise leading to uncompensable heat stress.
using 10 healthy male (age 27.3±8.76y, height: 1.77±0.03m, weight: 77.0±12.23kg, body fat: 11.0±5.87%; maximum oxygen uptake: 53.8±7.40ml•kg•1•min-1) volunteers. Participants’ maximal oxygen uptake was assessed during one trial, while in the second trial they entered an environmentally controlled chamber set at ambient temperature and relative humidity of 42ºC and 30%, respectively. During their first hour inside the chamber, participants were resting seated in a comfortable chair. Thereafter, they exercised to volitional exhaustion on a cycle ergometer at an initial workload equal to 20W with 20W increments every subsequent hour. Results showed that heat loss followed precisely the changes in heat production without substantial delay, while rectal temperature increased linearly with time. This was confirmed using auto-regressive, integrative, moving average (ARMA) time series analysis which showed that, unlike rectal temperature (t=0.569, P>0.05), heat loss (t=28.746, P<0.001) systematically followed fluctuations in heat production across time. In addition, the integral of heat storage (i.e., the integral of the difference between heat loss and heat production) did not differ statistically from rectal temperature across time. It is concluded that, under environmental heat exposure and increasing levels of heat production through exercise leading to uncompensable heat stress, the human body regulates heat loss and not rectal temperature. Further, under the conditions of the present experiment, rectal temperature is the eventuality of adaptations in heat loss and, in turn, in heat storage.

**SIMULATED ALTITUDE DURING THE NIGHT AMELIORATES SYMPTOMS OF ACUTE MOUNTAIN SICKNESS**

Boehm, A., Menold, E., Grigoriev, I., Bärtsch, P., Dehnhert, C.
Medical Clinic, University Hospital, Germany

Acute mountain sickness (AMS) occurs after rapid ascent to high altitude in otherwise healthy mountaineers. The risk of AMS is influenced by individual susceptibility, absolute altitude, rate of ascent and preacclimatisation. All these risk factors have been shown to have approximately the same weight. Since individual susceptibility and absolute altitude and in most cases also rate of ascent are given for a particular expedition or trekking tour, preacclimatisation is the only preventive factor that can be influenced individually. Thus we hypothesised that regular exposure to normobaric hypoxia during the night leads to ventilatory acclimatisation and reduces incidence and severity of AMS.

To test this hypothesis 75 healthy men at the age between 18 and 55 years were included in a randomized double blinded study. For preexamination subjects were exposed for 4 h at a FiO2 of 12% (approx. 4500m). Before and at the end of this exposure AMS (Lake Louise Ill-score, AMS-c score), ventilation and blood gases were assessed. Then an acclimatisation period of 14 nights in commercially available “hypoxia-tents” followed. Hypoxia (HYP) and control (CON) group received visually identical equipment which was technically adapted to the assigned group. Handling of the equipment was the same in both groups. All subjects were advised to set the level of hypoxia to a FiO2 of 15.4% (approx. 2500m) in the first night, then gradually decrease FiO2 each night by 0.2% until the final “altitude” of 3300m (FiO2=14%) was reached. This altitude then was constant until the 14th night. After a break of 4 days subjects were examined during one day (20 h, 3:00 p.m. – 11:00 a.m.) at FiO2 of 12%. Again AMS, ventilation and blood gases were assessed before, after 4 and after 20 h of hypoxia.

For technical reason most subjects did not reach the desired sleeping altitude of 3043m at average. We therefore analysed the 21 “highest” (=HYP) and the 21 “lowest” (=CON) according to the performed power analysis. Mean sleeping altitude in HYP was 2599m compared to 325m in CON. Both, LL- and AMS-c score were significantly reduced by sleeping in hypoxia (LL: 3.1±2.2 vs 5.6±3.6, p=0.039; AMS-c: 0.38±0.38 vs. 1.10±1.23, p=0,014). The reduction of oxygen saturation by 4 h of hypoxia was significantly less after acclimatisation in HYP, while there was no difference in CON. Ventilatory parameters showed no significant difference between HYP and CON. Sleepquality during the acclimatisation period in the tents was not affected by hypoxia.

The results of the study indicate that preacclimatisation during 14 nights in normobaric hypoxia reduces symptoms of AMS and therefore is useful to prevent AMS if acclimatisation in natural altitude is not possible. The effects can be expected to be even more pronounced if a higher degree of hypoxia can be attained in the tent.

**IMAGERY PERSPECTIVES AND MODALITIES: AN INVESTIGATION OF THREE ISSUES**

Roberts, R., Callow, N.
Bangor University, United Kingdom

The present study explored three issues in imagery perspective and modality research: the angle used to imagine performing a movement when using external visual imagery (EVI); the relationship between imagery perspective preference and imagery ability; and the order with which visual and kinaesthetic imagery are experienced. One hundred and fifty nine athletes (M age = 19.6 years, SD = 2.67) completed the Vividness of Movement Imagery Questionnaire 2 (VMIQ-2). Roberts, Callow, Hardy, Markland, & Bringer, 2008, which assesses internal visual imagery (IVI) ability, EVI ability, and kinaesthetic imagery (KIN) ability. On completion of the VMIQ-2, participants completed three further questions. First, they marked the angle that they imaged from when completing the EVI factor on a 3-D diagram. Second, they rated their preference for using a particular visual imagery perspective on a Likert type scale from 0 (strong preference for IVI) through to 5 (no preference) to 10 (strong preference for EVI). Finally, participants reported whether they experienced KIN when completing the IVI and EVI factors of the VMIQ-2. If participants did experience KIN, they were asked to highlight the order (i.e., visual and kinaesthetic concurrently, visual then kinaesthetic, kinaesthetic then visual) that the two modalities were experienced. To assess whether the angle of EVI affected EVI ability, responses from the angle question were inspected, and the number of times each angle was reported by participants was summed. Although participants reported imaging from a variety of external angles, the four most common angles were from above, behind, from the right, and from the left. A single factor ANOVA revealed no significant difference in EVI ability between these four angles. To examine the relationship between imagery perspective preference and imagery ability, correlations were performed between the preference scale and the requisite factors of the VMIQ-2 (i.e., the IVI and EVI factors). Results revealed moderate significant...
correlations between preference and ability (r = -0.301 for EVI and r = -0.317 for IVI). The order data revealed that for EVI, participants reported experiencing visual imagery and kinaesthetic imagery concurrently to the same extent as visual then kinaesthetic imagery. However, these orders were experienced significantly more often than kinaesthetic then visual imagery. For IVI, visual and kinaesthetic imagery were experienced concurrently more often than visual then kinaesthetic imagery, and also kinaesthetic then visual imagery. The results are discussed in terms of their implications for both research and applied practice.

SELF-TALK CAN MEDIATE THE EFFECTS OF AUTONOMY-SUPPORTIVE AND CONTROLLING ENVIRONMENTS ON MOTIVATIONAL STATE

Oliver, E., Markland, D., Hardy, J.
Bangor University, United Kingdom

Using Self-Determination Theory as a theoretical framework, this study examined whether self-talk mediates the effects of social contexts on individuals’ motivational state. Within sport, relative to controlling contexts, autonomy supportive environments elicit more self-determined forms of behavioural regulation, greater persistence, and enhanced well-being (e.g., Pelletier, Fortier, Vallerand & Brière, 2001). Additionally, there is evidence that self-talk mediates the effects of social factors, such as coaches’ behaviours, on outcomes including athletes’ fear of failure and self-concept (e.g., Conroy & Coatsworth, 2007). As such, a model was tested by which the type of self-talk used by individuals varies as a function of social context, and that this in turn causes changes in one’s motivational and affective state.

70 male and female student volunteers (mean age = 24.19, sd = 9.07) were randomly assigned to an autonomy-supportive or controlling condition. Participants were instructed to ‘think-aloud’ throughout a ten-minute computerised task and self-verbalizations were recorded. A five-minute-free-choice period followed, after which participants completed the Intrinsic Motivation Inventory (Perceived choice, Interest / Enjoyment / Pressure / Tension subscales). Lexical frequency analysis software was used to examine self-talk transcripts. Independent t-tests identified that participants in the autonomy-supportive condition used significantly more positive emotional words (p = .004) and positive assertions (e.g., yes, ok) (p < .001), fewer swear words (p < .05), fewer anger words (p = .054), and reported significantly greater interest and enjoyment (p < .001) and spent longer on the task during a free-choice period (p < .01). Multiple mediator analyses revealed that certain self-talk factors predicted motivational outcomes and furthermore, some acted as mediators in the manner hypothesised. For example, 1st person speech was a significant mediator of the relationship between social context and interest/enjoyment, with autonomy-supportive contexts predicting fewer 1st person self-talk, which in turn negatively predicted interest and enjoyment. In addition, 1st person speech partially mediated the effects of social context on perceived choice, with greater perceived choice predicted by lower levels of 1st person speech. This study highlights the importance of theory-based research into the antecedents and effects of self-talk.

HEART RATE PATTERNS AND FOCUS OF ATTENTION DURING BALANCE BEAM PERFORMANCE

Cotyn, J., De Ciercaq, D., Crombez, G., Lenoir, M.
Katholieke Hogeschool Zuid-West-Vlaanderen, Gent University, Belgium

Preparatory heart rate (HR) deceleration is believed to be a marker of optimal functioning of attentional processes leading to excellent performance and is related to an external focus of attention (Radlo et al., 2002). An external focus of attention has been associated with optimal balance performance (for review, Wulff, 2001). However, research on sport related complex balance movements (e.g., gymnastics) appear to be limited.

The preparation period of an acrobatic element (flic flac) on the balance beam was studied in fourteen female gymnasts. HR was measured beat-per-beat with a telemetric heart rate monitor and four time points during the preparation period (T1 at the beginning, T2: mean during the first half, T3: mean during the second half, T4: at the end) were calculated in order to investigate the HR deceleration effect. A significant HR deceleration (F[3,33] = 8.16, p < 0.001) was found during the preparation period of the attempts with a fall in the consecutive acrobatic element. No HR deceleration (F[3,33] = 2.59, NS) was found in the attempts without a fall. These data suggest that preparatory HR deceleration is associated with a detrimental effect upon the performance of complex balance movements. Thus, the findings question the generalization of the beneficial effect of an external focus of attention on balance. An external focus of attention is defined as attention that is directed to the effect of the movements on an apparatus or implement. In the present study, the balance beam is a static apparatus, which by definition is unable to give additional information on the movement effect. In literature, the beneficial effect of an external focus of attention has been demonstrated in dynamic balance tasks on a stabilometer, but not in static balance tasks. Moreover, several authors demonstrated that gymnasts shift their sensorimotor dominance from vision to proprioception (Vuillerme et al., 2001), indicating that an internal focus of attention could be beneficial in balance beam performance. A direct manipulation of the focus of attention is necessary to further explore the role of preparatory HR deceleration on the performance of complex movements on the balance beam.

IS SPORT MOTIVATION IN YOUTH RELATED TO THE OUTCOME SUCCESS IN ADULTHOOD? EVIDENCE FROM DUTCH FIELD HOCKEY PLAYERS

Elferink-Gemser, M., Medic, N., Starkes, J., Jordet, G., Visscher, C.
1 University of Groningen, UMCG, 2 The University of Western Australia, 3 McMaster University Hamilton Canada, 4 Norwegian School of Sport Sciences Oslo, Netherlands

The developmental course of professional performers from childhood to adolescence has been shown to be fundamentally different from that of amateurs. Differences exist in terms of number of hours devoted to improvement of current levels of performance and in the quality and quantity of practice. Unlike amateurs, professionals continuously seek excellence, are highly motivated to improve and do well, and continue to practice with effort. Unknown, however, is whether this also holds for a group of talented youth athletes; i.e., athletes who are better than their peers during training and competition (Elferink-Gemser et al., 2004). Although during their developing years all are expected to have the potential to reach elite level, only few of them eventually do.

To examine whether sport motivation during youth years is predictive of sport outcome success in adulthood, 98 talented field hockey players (mean age 16.5, sd 1.1) filled in the Task and Ego Orientation in Sport Questionnaire and the Sport Motivation Scale. Based on their performance level three years later, they were divided into elite (n=21) and non-elite players (n=77). Unlike non-elite, elite players competed in the highest national Dutch field hockey competition. Multivariate analyses were conducted to examine if motivational differences were evident across performance levels. In addition, Spearman correlations between motivational variables and training characteristics were examined.

All talented players scored high on motivation when compared to population scores (p<.05). Compared to non-elites, elite players reported higher levels of intrinsic motivation (to experience stimulation and to accomplish), identified regulation, and external regulation when they were younger (p<.05). The number of field hockey specific training hours per week was positively related to intrinsic motivation (r = .23, p<.05), the number of field hockey matches to external regulation (r = .25, p<.05).

In a group of all talented youth field hockey players aged 15-18, sport motivation is related to training characteristics and outcome success. The building of a solid foundation of intrinsic motivation seems paramount in the development of highly successful, self-determined experts (Ryan & Deci, 2000). In line with Ericsson's expertise model (1998) talented youth field hockey players who ultimately reached elite level of performance had higher motivation when they were younger than those with an arrested development. Examination of a relation between motivation, practice, and outcome success has been suggested in literature but attempts to provide empirical evidence have been very limited to date. Results from the present study are amongst the first to provide support for a positive relation between sport motivation, practice, and outcome success.

SELF-REGULATION AND PERFORMANCE LEVEL IN YOUTH SOCCER PLAYERS

Toering, T., Elferink-Gemser, M., Jordet, G., Visscher, C.
Center for Human Movement Sciences Groningen, University Medical Center Groningen, University of Groningen, Netherlands

Why do some athletes reach the top in their sports while others fail to succeed? This question has frequently been asked in talent identification and development research. In their review on talent identification and development research in soccer, Williams & Reilly (2000, p.660) claimed that ‘a talented player possesses personality characteristics that facilitate learning, training, and competition’. Self-regulation, the ability to exert control over one’s metacognitive, motivational, and behavioral processes (Baumeister & Vohs, 2004; Zimmerman, 1986), might be such a characteristic that talented players can use to develop performance. The purpose of this study is to examine the relationship between self-regulation and performance level in youth soccer players.

Self-regulation was assessed with a questionnaire containing the following aspects of self-regulation: planning (= .79), evaluation (= .82), reflection (= .75), self-efficacy (= .78), and effort (= .84). The 388 participants were youth male soccer players aged 11 to 17 years (mean age ± SE: 13.90 ± 1.39 years). Players were classified in talents and regional players. In contrast to regional players, talents played in the U13, U15, or U17 youth soccer team of a professional soccer club at the highest national competition level in the Netherlands. Multivariate and univariate analyses of covariance were conducted. A significance level of .05 was adopted and we corrected for multiple tests.

The results revealed that talents scored significantly higher than regional players on effort and reflection. Because of the correction for multiple tests, for self-monitoring only a trend was visible, with talents scoring higher than regional players.

Talents outscored regional players on effort and reflection, which may mean talents invest more effort in practice and are better able to translate what they know into what they do. In many self-regulation studies effort has been studied as a motivational component (Hong & O’Neil, 2001). Deliberate practice is not always motivating, but commitment to practice is very important, since for expert performance a long period of sustained effort to improve performance is needed (Ericsson et al., 1993). Reflection is the key process of expert learning, which translates knowledge into action, making it possible to gain strategy knowledge from specific activities (Ertmer & Newby, 1996). Because of their better scores on effort and reflection, talents may be better able to develop their performance than regional players.

SYNCHRONIZED SWIMMERS MOTIVATIONS FOR THE ACTIVITY

Macara, A., Vieira, S.
Faculdade de Motricidade Humana, UT Lisbon, Portugal

Introduction
Synchronized swimming is a relatively young sport, but its development has been important in terms of numbers of practitioners as well as the quality of performance (Pawson, 2005).
Several authors (Vickers, 1965; Lundholm, 1976; Elkington & Chamberlain, 1986) appeal to the educational and fitness value of this modality. In this paper, we will present part of the results of a larger study concerning the positive and negative motivations of synchronized swimmers towards the activity.

Methods
From a total population of 38 swimmers in the region of Lisbon, Portugal, a total of 31 have collaborated in our study. A sub-group of 11 are federated, competition athletes. The other 20, non-federated, belong to exhibition groups.

A specific questionnaire was used to understand how these athletes relate to their preferred sport. We inquired about what they prefer in the activity, and what they dislike the most in this practice, to completely open questions. The questionnaires were applied by direct application. The data was treated by content analysis, looking for the most frequent categories of answers, in order to better understand the subjects motivations.

Results
This study allowed us to bring out the most important factors influencing the practice, and some differences between federated and exhibition athletes.

The federated athletes, mostly used to practice for competition value mostly the expressive and creative aspects, related to the creation of the choreographies, followed by the pleasure of the contact with the water, on one side, and the team spirit and human relations. The synchronization movement music and the development of fitness qualities are also mentioned by approximately half of the subjects.

In the non-federated sub-group, the synchronization with the music/dancing aspects are the most valued, immediately followed by the importance of team work, the control of the body in the water and the variety of activity. In this sub-group, there are very few items they dislike in this activity.

The federated athlete has more negative impressions about the activity, mostly related to the bad moments in competition and problems with the evaluation, but also with the lack of infra-structures for the modality.

OP-SM02 Sports Medicine 2 - General

DOES STANDARD ISOKINETIC EVALUATION REFLECTS OF FIRST 30° RANGE’S RESULTS ON HEALTHY PEOPLE?
Aydog, S., Horodyski, M.
Hacettepe University Department of Sports Medicine, Turkey; University of Florida, United States

Background: Clinicians generally use the peak torque (PT) of concentric hamstring (H) to PT of concentric quadriceps (Q) ratio (conventional H/Q ratio) and PT of eccentric H to PT of concentric Q ratio (functional H/Q ratio) for isokinetic strength evaluation in 90° of range of motion. But, the range for the angle of PT is between 40°-75° for the Q and 17°-47° for the H. And biomechanical and video analysis methods show us, non-contact ACL injuries frequently occur when the knee is close to full extension combined with some rotation of the tibia.

So, evaluation of the first 30° (ACL sensitive area) might be better than the evaluation of the full range.

Objective: This study was conducted to compare between the standard isokinetic results and first 30° range’s results.

Design: We evaluated cross-sectionally 31 healthy subjects (21 female and 10 male). We provided two teaching sessions for subjects to familiarize with the testing procedures for the isokinetic testing. All subjects had been tested bilaterally in four isokinetic conditions: one velocity (60°/s), two modes (concentric, reciprocal eccentric), two ranges (30°-limited, 90°-full). A one min rest between testing conditions allowed for re-adjustment of the isokinetic dynamometer.

We correlated between limited and full isokinetic evaluations.

Results: There was no correlation on functional H/Q ratio between limited and full range. But the study showed correlation on conventional H/Q ratio between limited and full range (r: 0.507, p<0.000). There were no correlation between functional H/Q ratio and conventional H/Q ratio for limited and full range.

Conclusion: These data indicate evaluation of the full range of isokinetic knee strength is not reflects limited range of knee strength. So, evaluation of the limited range might be better for ACL sensitive area.

THE INTERACTION BETWEEN EXERCISE AND CYCLOSPORINE-A IN ANTIOXIDANT CAPACITY AND OXIDATIVE STRESS IN MOUSE SKELETAL MUSCLES
Chi-Wei, C., Yei-Chun, C., Pei-Yu, S., Wei, H., Shih, H., Chen-Kang, C.
Taiwan Sport University, Taiwan

Cyclosporine-A (CsA) is a commonly used immunosuppressive agent in organ transplantation. CsA has been reported to reduce antioxidant capacity. Regular exercise training has been shown to increase antioxidant enzyme activities. The purpose of this study was to investigate the effect of exercise and CsA on antioxidant capacity and oxidative stress in mouse skeletal muscle.

Forty-eight adult female BALB/c mice were randomly assigned to one of the 6 groups: 0-Ex (no CSA, no exercise), 0+Ex (no CSA, exercise), 10-Ex (10 mg/kg/d CSA, no exercise), 10+Ex (10 mg/kg/d CSA, exercise), 20-Ex (20 mg/kg/d CSA, no exercise), 20+Ex (20 mg/kg/d CSA, exercise). The 3 exercise groups were trained 3 times a week at approximately 75% VO2max for 6 weeks. Activities of antioxidant enzymes, oxidative stress markers, and total antioxidant status (TAS) were analyzed in quadriceps with commercial kits. The data were analyzed by two-way ANOVA.

Data was presented as mean±SD. There were significant exercise, drug, and exercise x drug effects in SOD, GPX, and TAS. In non-exercise groups, CSA significantly reduced activities of SOD (0-Ex: 7.93±2.17, 10-Ex: 7.20±1.42, 20-Ex: 7.40±1.46 U/mg protein) and GPX (0-Ex: 1.84±0.28, 10-Ex: 1.48±0.24, 20-Ex: 1.56±0.26 U/mg protein) and TAS (0-Ex: 0.57±0.15, 10-Ex: 0.44±0.04, 20-Ex: 0.43±0.06 nmol/mg protein). On the other hand, exercise prevented the CsA-induced reductions in activities of SOD (0-Ex: 7.25±1.58, 10-Ex: 7.0±1.46, 20-Ex: 10.0±1.42 U/mg protein) and GPX (0-Ex: 1.55±0.28, 10-Ex: 1.63±0.30, 20-Ex: 2.03±0.27 U/mg protein) and TAS (0-Ex: 0.43±0.05, 10-Ex: 0.49±0.06, 20-Ex: 0.41±0.08 mol/mg protein). There were significant exercise, drug, and exercise x drug effects in protein carbonyl (PC) concentration. PC levels were similar in the 3 non-exercise groups (0-Ex: 92.9±30.4, 10-Ex: 74.1±50.1, 20-Ex: 71.5±20.2 nmol/mg protein).
The study compares the arthrokinematics of asymptomatic handball players with six handball players demonstrating borderline grade I internal impingement. Intra-articular glenohumeral kinematics was assessed by means of 3D reconstruction of helical CT-scans in 90° abduction/90° external rotation and the apprehension test pose. Osteokinematic ex/intershoulder rotation and posterior shoulder tightness was assessed goniometrically. Scapularoactivity motion was evaluated using electromagnetic trackers.

Internal impingement III presented with an augmented intra-articular external rotation angle (+32.3°, +28.6°, +32.7°) compared to the asymptomatic shoulders (AS: [-0.5°, ±0°]). In the apprehension test, III presented a posterior position of the humeral head on the glenoid (-6.8°, -7.4°, -6.2 mm) comparable to the AS (-7.6°, -8.5°, -6.4 mm) and also no apparent differences for superior position.

III presented with an internal rotation deficit (IRD) of -35.5±7.6° or 1.2 SD under the average in Meyers study (1), a posterior shoulder tightness of -8.9±1.2 mm or 1.0 SD under the average in Meyers study (1), and an external rotation gain of 30.6±3.7° or 2.4 SD above the average in Meyers study (1). This tightness has been hypothesized by Burkhart et al. (2) to result from shifting the glenohumeral fulcrum posterosuperiorly, hence increasing contact of the rotator cuff and labrum. However, despite the IRD and posterior shoulder tightness found, no significant differences in superior and posterior position of the humeral head on the glenoid cavity could be demonstrated with external rotation. As such, IRD and posterior shoulder tightness may be related to internal impingement but not in the hypothesized causal cascade point of view. The only difference found between II and AS was the enhanced intraarticular glenohumeral external rotation. II might be compounded with scapula dysfunction. Recently, Laudner et al. (3) demonstrated that throwers with II exhibit an increased sternoclavicular elevation during humeral elevation from 30 to 120°, an increased posterior scapular tilt position and a more protracted scapula. However, in this study scapularoactivity position and rotation during scaption remained within one SD of the AS measurements presented by Laudner et al. (3).

lipids and glucose. Furthermore, a prospective analysis, pre and post the intervention analysing 60 obese children of the same age with respect on equal parameters. Additionally non-invasive sonographic measurements of carotid IMT were performed. Results: Main outcomes of the retrospective study were as follows: Average BMI of 31.72 kg/m² (+/- 5.73) at the beginning and of 28.56 kg/m² (+/- 5.20) at discharge, equivalent to an average reduction of 10% body weight. Systolic blood pressure in 25.1% of the patients above the 95th percentile, total-cholesterol in 69.9% above age related norm values, LDL-cholesterol in 73.4% increased, glucose in 41%. A stra ng positive association (p<0.01) of the pathologies with weight classifications was found. Especially in extreme obese patients, significant reductions of all examined parameters were investigated after the intervention. Prospective study: IMT with a mean of 0.517 +/- 0.049mm was above age related healthy peers without significant reduction at discharge.

Conclusions: There is a high incidence of subclinical and evident cardiovascular and metabolic disease. The alterations of the analyzed cardiovascular risk factors were positively associated with the weight loss throughout the intervention program. Increased IMT is present in the obese paediatric population. In advantage to invasive diagnostics, the ultrasound measurement can demonstrate the effect of the intervention program clearly on the level of the vascular system since it enables an insight into the health of the blood vessel, but obviously pathological changes need longer time to be reduced.

PHYSICAL ACTIVITY IN DIABETES PATIENTS AND HEALTHY SUBJECTS
Karjalainen, J., Kiviniemi, A., Hautala, A., Huikuri, H., Tulppo, M.
Verve, Finland

BACKGROUND: Physical activity is a well recognized and recommended treatment for diabetes patients. However, the physical activity levels among elderly diabetes patients and age matched healthy subjects are not well known. The purpose of this study was to measure long-term physical activity among coronary artery disease (CAD) patients with type II diabetes and age matched healthy subjects.

METHODS: Maximal oxygen uptake was measured by bicycle ergometer with 12-lead ECG recordings for 12 healthy subjects (61±5 years) and for 13 CAD patients with diabetes (age 61±5 years). None of the healthy subjects have any clinical changes in ECG during exercise test. After the exercise test the physical activity was measured over 7 days during waking hours by Polar AW200 device.

RESULTS: The maximal oxygen uptake was 23±6 ml/kg/min for patients and 30±7 ml/kg/min for healthy subjects (P<0.05). The average physical activity measured over 7 days was 25±5 kcal/kg/waking hours for patients and 31±4 kcal/kg/waking hours for healthy subjects (P=0.005) corresponding as an average 1.96±0.27 vs. 1.62±0.39 METs (P<0.05). Patients had a higher BMI (30±4 vs 25±4, P<0.005) and HbA1c levels (6.0±0.8 vs. 5.2±0.3, P<0.03) compared with healthy subjects. Systolic and diastolic blood pressure was at the same level between patients and healthy controls (85±6/141±17 vs. 84±4/141±19 mmHg, for patients and healthy subjects, respectively).

CONCLUSIONS: Elderly diabetes patients have reduced physical activity compared to age matched healthy subjects. Community wide strategies to increase physical activity among diabetes patients are warranted.

VEGF CONTENT AND BLOOD FLOW IN HUMAN PATELLA TENDON AFTER ACL RECONSTRUCTION
Bayer, M., Mikkelsen, K., Boesen, M., Kjaer, M., Langberg, H.
Institute of Sports Medicine Copenhagen, Denmark

ACL ruptures are common sports injuries, and surgically obtained autographs from the mid-portion of the patellar tendon are routine procedures for reconstruction. However, this has a severe impact on the patella tendon with poor healing prognosis. Generation of patellar tendon after autograft surgery has remained an under-researched area and the aim of this study was to examine progression of the healing in the mid-portion of the patella tendon after surgery and the involvement of different growth factors. One of these growth factors with a potential role is Vascular Endothelial Growth Factor (VEGF), a major angiogenic factor (Petersen et al., 2003).

Subjects underwent ACL reconstruction six (n= 7) and 24 months (n= 7) prior to the experiment. Microdialysis catheters were inserted through the peritendinous space at mid-patella to measure the content of VEGF (Langberg et al., 1999). The blood flow in the area was determined with the Ultrason-sonography Doppler technique. The contralateral, healthy tendon served as a control.

Six months post surgery, patellar tendon revealed increased VEGF synthesis and enhanced blood flow compared to control (P< 0.05).

Both VEGF and blood flow were back to basic and not significant different from the control tendon 24 months following harvesting.

The observed increase in blood flow 6 months post surgery indicates that neovascularisation in the mid-portion of healing tendon takes place and that VEGF may play a role in the healing response in traumatized tendon. Although augmented blood supply might benefit regeneration, VEGF is also known to be related to induction of hyperemia in degenerative tendon. Noteworthy, the results suggest a relatively short-termed response due to the decline of increased blood flow 24 months post operation, i.e. an induction of new blood vessels as an early phase response, which decreases again during tendon regeneration.

The present study reveals VEGF induction and enhanced blood flow in human tendon after ACL reconstruction and proposes essential healing mechanisms. I recommends further studies on VEGF, its potential role in angiogenesis of regenerating tendon and possible negative effects of VEGF.

KNEE INJURIES IN TEAM SPORTS: EVALUATION AND ASSESSMENT OF RISK FACTORS
Moschny, A., Henke, T., Platen, P.
Ruhr-University Bochum, Germany

Purpose: Presently, there is a trend towards individualising the training process in team sports to efficiently develop the respective athletes' performance. With regard to sports injuries, such a development would be desirable for preventive training as well. Up to now, injury prevention measures are generally used for an entire team. Thus, individual factors predisposing single athletes for specific injuries remains disregarded. Similarly to performance diagnostics in ball sports, there is a need for assessment tools to evaluate the athletes' predisposition for specific injuries according to established risk factors. A suchlike prediction of injury risk could result in individualised injury prevention training.

Methods: Sports club members who reported their injury to the insurance company received a questionnaire containing questions with regard to the circumstances of the accident, the injury itself and the treatment. Currently, the database contains approximately 170,000 sports club injuries. Information on gender, age, previous injuries, height, weight and BMI will be included in analyses. Additionally, literature relating to intrinsic risk factors and assessment tools has been compiled.

Results: Analysing German club sports, football (fb), handball (hb), basketball (bb) and volleyball (vb) result in highest frequencies of injuries. In these ball sports the lower extremities are most frequently injured (fb=61.5%, hb=51.7%, bb=62.1%, vb=69.9%). Muscle strains as well as ankle and knee ligament sprains are dominating. Since knee ligament and more precisely ACL injuries are not only frequent but also serious injuries, they have been analysed concerning risk factors in the following. Thereby, according to the residuals, the relation between knee ligament injuries and female gender, previous injury as well as higher age is higher-than-average. Moreover, residual values for knee injury prevention tools do not seem to be related to knee ligament injuries.

Conclusions: Aiming to own data analyses and a literature review female gender, previous injury and higher age are well-established risk factors for knee injuries. Additionally, an increased Q-angle, general ligament laxity, mechanical instability of the knee, excessive foot pronation as well as proprioceptive and strength deficits seem to be risk factors, all abetting a dynamic valgus position being a risk factor itself. Measures to assess the respective risk factors for knee injuries are suggested. They encompass assessment of leg alignment, mobility, stability and functional movement. Thus, athletes at risk may be identified and consequently may be given the chance to work up their individual deficits to prevent knee injuries.

GLYCINE-ARGININE-ALPHA-KETOISOCAPROIC ACID DOES NOT IMPROVE PERFORMANCE OF REPEATED SUPRAXIMAL CYCLING SPRINTS IN TRAINED CYCLISTS
University of Glasgow, United Kingdom

Amino acids are essential for protein synthesis and muscle formation and are involved in numerous metabolic pathways affecting exercise metabolism. Consequently, it has been suggested that athletes involved in intense training and competition, supplement their diet with specific amino acids. For example, oral supplementation with glycine-arginine-alpha-ketoisocapric acid (GAKIC) has previously been shown to improve performance during exhaustive high-intensity anaerobic isokinetic exercise [1] and attenuate the decline in mean power during five repeated cycle sprints [2]. PURPOSE: The aim of the present study was to examine the effects of GAKIC on fatigue during repeated supramaximal repeated cycle sprints in trained cyclists. METHODS: After at least two familiarisation tests, seven well-trained male cyclists (Aged 25-44 years) completed two supramaximal sprint tests each involving 10 sprints of 10 s separated by 50 s rest intervals on an electrically braked cycle ergometer. Computer software was used to calculate mean and peak power output and the fatigue index. During a period of 45 min prior to the two experimental trials, subjects ingested 11.2 g of GAKIC (2.0 g glycine plus 6.0 g l-arginine monohydrochloride plus 3.2 g (alpha)-ketosocaproic acid calcium salt) or placebo (Pl) (composed of 9.46 g sucrose plus 3.2 g calcium carbonate) administered in a randomised and double blind fashion. Supplements were dissolved in 450 ml of sugar free fruit juice, divided into 3 equal aliquots of 150ml and consumed 30, 20 and 20 min prior to the trial. RESULTS: Peak power declined from the 1st sprint (mean +/- s.d.) (Pl: 1332 +/- 307, GAKIC: 1367 +/- 342 W) to the 10th sprint (Pl: 1091 +/- 229, GAKIC: 1061 +/- 272 W) but did not differ between treatments (P=0.88). Power mean declined from the 1st sprint (Pl: 892 +/- 151, GAKIC: 892 +/- 153 W) to the 10th sprint (Pl: 766 +/- 120, GAKIC: 752 +/- 138 W) but did not differ between treatments (P=0.96). In general, the fatigue index remained stable at ~38% throughout the series of sprints and did not differ between treatments (P=0.99). The subjective rating of perceived exertion increased from 766 +/- 120, GAKIC: 752 +/- 138 W) but did not differ between treatments (P=0.99).

MONITORING TRAINING LOAD IN YOUNG ELITE SOCCER PLAYERS
Lemmink, K., Brink, M.
University Medical Centre Groningen, University of Groningen, Netherlands

Monitoring training load in young elite soccer players is important for optimizing their performance and avoiding overtraining. Methods using Rate of Perceived Exertion (RPE) have become popular for this purpose, especially in endurance athletes. However, validity of this method is largely unknown, especially in young elite soccer players [1]. The purpose of this study was to validate the RPE method in young elite soccer players by comparing the RPE method with the Modified TRIPW method, a well-known method based on heart rate measurements [2].

Monitoring training load in young elite soccer players is important for optimizing their performance and avoiding overtraining. Methods using Rate of Perceived Exertion (RPE) have become popular for this purpose, especially in endurance athletes. However, validity of this method is largely unknown, especially in young elite soccer players [1]. The purpose of this study was to validate the RPE method in young elite soccer players by comparing the RPE method with the Modified TRIPW method, a well-known method based on heart rate measurements [2].
Two age groups of young elite soccer players, i.e., 17 players with a mean age of 17.8±0.4 years and 14 players with a mean age of 14.6±0.5 years, all playing for a professional soccer club on the highest level in the Netherlands, participated in the study. Four respectively 6 training sessions with different training intensities were monitored in the oldest and youngest age group using the RPE method (RPE × duration) and the (modified) TRIMP method. Data were analyzed using Pearson Correlation Coefficients.

In both age groups results showed a reasonable relationship between the RPE method and the (modified) TRIMP method with correlation coefficients of 0.67 and 0.65 for the oldest age group and 0.66 and 0.67 for the youngest age group (p<0.01). At individual level, 24 out of 31 players showed a correlation coefficient of 0.80 or higher.

The RPE method seems a reasonable method to monitor training load of a team of young elite soccer players on a daily and weekly basis. However, some players have problems in rating the perceived exertion of their training sessions. Those players should be trained properly in using the RPE method.

ATHLETIC PERFORMANCE EVALUATION SYSTEM
Silva, H., Martins, G., Mil-Homens, P., Valamatos, M.
PLUX Engenharia de Biosensores Lda., Portugal

In order to design an athlete’s follow-up or training program, a quantitative knowledge of the evaluated physical condition is needed[1]. The use of technology in this task[2] is becoming more usual, introducing automation and new insight to the evaluation process and results.

We present a pilot installation for an integrated athletic performance monitoring and evaluation system, which comprehends: (a) wireless measurement sensors and data acquisition hardware, (b) data analysis and reporting software modules, and (c) integrated athlete and protocol management software modules. The system works on a workstation/protocol basis. Each workstation is instrumented with a wireless measurement unit that collects the signals from the corresponding sensors. The acquired data is transmitted in real time to a base station via Bluetooth, where they are processed and represented. Each workstation is instrumented with the appropriate wireless sensor kit and can assess multiple parameters. The athlete has real-time feedback about his performance during the evaluations, with automated visual and acoustic aids to support the protocol execution.

The athlete’s progress history can be accessed allowing the follow-up and performance gains comparison throughout different evaluation sessions. The software consists of 5 modules: sensor control, acquisition and display, automatic signal processing, reporting and database. Currently three workstations are predefined: (a) leg-press: with force sensors for evaluation force production characteristics of the lower extremities, (b) jumping: with a force platform for evaluation of reactive force and related parameters in squat, countermovement and drop jumps; and (c) multi-power device: with a displacement sensor and a force platform for evaluation of dynamic parameters, such as power and velocity [3, 4].

Each evaluation session is defined by a protocol that is specifically created by the coach for the athlete, in which he chooses what workstations and evaluations will be executed by the athlete as well as their sequence. This provides a comprehensive evaluation which objectively shows the athlete’s strengths and weaknesses, allowing the design of a specific and optimized training program.

TALENT IDENTIFICATION IN YOUNG BASKETBALL PLAYERS
Vieira, F., Marqueses, P., Carita, A.
IFaculty of Human Kinetics, Technical University of Lisbon, Portugal

Introduction
Talent Identification (TID) is crucial for the selection of high performance athletes. Yet, TID is most frequently based on subjective criteria (coaches’ perception). The aim of this study is identifying the variables that best predict U-16 masculine basketball players’ success using different groups of variables.

Methods
Our sample consists of 83 Basketball male athletes aged 14-16. The morphological variables were obtained according to ISAK norms described by Fragoso & Vieira (2005). The equations of Slaughter et al. (1988) and Lohman (1986) were used to calculate relative fat and the ones proposed by Carter (1996) to determine somatotype. Fitness level was assessed with 7 field tests and questionnaires were used to assess technical/tactical and psychological variables. Maturational measures consisted of a skeletal age evaluation obtained according to TW3 method (Tanner et al., 2001) and the sexual maturity was self-evaluated according to Tanner (1962). The descriptive statistic and the logistic regression were generated by SPSS 15.

Conclusion
The explaining variables included in the final model were: sitting height (SH), horizontal jump (HJ) and long basketball throw (BT). The logit of the fitted logistic regression model is:

\[ g(x) = -84.113 + 0.725 * SH + 1.839 * BT + 0.058 * HJ \]

The odds ratio showed that an increase of one centimetre in SH almost duplicates the probability of being selected, that one cm more in BT, the same probability increases 6.3 times and for each cm increase in HJ the probability only raises 1.1 times.

The adjusted model is significant (2 loglikelihood = 25.537, p< 0.001) and shows a R2 of Nagelkerke of 0.843. Regarding the percentages of correct classifications found to the model described (93.9%) we may conclude that it seems to be an adequate one for talent identification in this sport.
ANALYSIS OF PLAYER INTERACTIONS IN SMALL-SIDED SOCCER GAMES

Frencken, W., Otten, E., Visscher, C., Lemmink, K.
University Medical Center Groningen, University of Groningen, Netherlands

Both time-motion and notational analyses have identified key determinants for successful performance in soccer. From this, optimal strategies and tactics are developed. However, less attention has been paid directly to tactics and player interactions in soccer. Yet, professional soccer clubs ‘scout’ their opponents, in order to identify patterns in game play. Therefore, tactics seem to be a crucial factor for success. This is supported by findings of Borrie et al. (2002), who have shown that successful teams display more and richer patterns, whereas compared to less successful teams. In this light, dynamical systems theory (DST) provides a sound theoretical framework for the analysis of player interaction patterns in match situations. Previously, McGarry et al. (2002) suggested that during a match, players are coupled. These couplings are not fixed, but formed and broken continuously, both within and between players and teams. In this study, the purpose was to investigate these couplings. Therefore, we analyzed players’ speed and acceleration profiles during 4 small-sided soccer games (4-a-side). Positional data (x,y) of elite youth soccer players (U19’s) was recorded at 1000Hz, using Local Positioning Measurement (LPM, Inmotio Object Tracking, Amsterdam, the Netherlands). In addition, the centers of both teams (mean(x,y)) were analysed similarly. Cross-correlations of speed and acceleration profiles were calculated over sliding 2,5s intervals, for all individual players and the centers of both teams. Preliminary results show that overall, all players are positively cross-correlated during small-sided games. Smallest player coupling values are found for both goalkeepers with all outfield players. On numerous occasions, decreases in couplings coincide with critical moments in the game, indicating perturbations. Finally, analyses show that calculations of cross-correlations are more sensitive for player interaction patterns in match situations. It can be concluded that couplings between individual players and between teams can be measured properly using cross-correlations of acceleration profiles when compared to speed profiles. It can be concluded that couplings between individual players and between teams can be measured properly using cross-correlations of acceleration profiles. In addition, results indicate that perturbations can be identified by decreased or negative correlations. These analyses are very promising in the light of dynamical systems and performance analysis and require further investigation. Above results will be discussed along with practical implications and suggestions for future research.

OP-TT05 Training and Testing 5 - Training

RESISTIVE TRAINING OF VARIOUS INTENSITIES: EFFECTS UPON FORCE-VELOCITY AND MORPHOLOGICAL INDICES

Vinogradova, O., Netreba, A., Popov, D., Lyubaeva, E.
SSC RF Institute of biomedical problems RAS, Russia

The study was designed to reveal the effect of resistive training intensity upon physiological and morphological indices of trained muscle. Responses to 8-week resistive training at various intensities were investigated in 30 male subjects using a leg press exercise machine. Training loads were approximately 20-25%, 60-70% and 85-90% of one repetition maximum (1 RM) for low (LI), medium (MI) and high intensity (HI) training groups, respectively. The medium intensity training was performed without relaxation, i.e. under conditions of restricted blood supply. The total work done during the training session was identical for 3 groups. The increments of muscle strength in trained multi-joint movement were quite different in LI- and HI-groups, but in one-joint movement (knee extension) differences between the groups disappeared. It might be connected with biomechanics of movements and with the types of muscles involved. Velocity trained HI-group demonstrated the lowest increases of maximal speed of leg extension. Maximal increases of speed were recorded in HI-group which used highest external loads with rather slow speeds. That observation confirmed the speculation that muscle contraction speed is a function of its strength potential. Analysis of knee extension isokinetic torques produced under concentric and eccentric conditions revealed no differences between HI- and LI-groups. Medium intensity training without relaxation did not induce strength increments in eccentric regime. This result might be connected with practically absent stroke loads in MI-group in comparison with other groups. Medium intensity training without relaxation led to a decrease of IEMG-activity of m. vastus lateralis during maximal knee extensions in the whole range of angular velocities tested. At the same time HI-group demonstrated the opposite tendency and LI-group did not demonstrate significant changes of IEMG activity. We believe it to be connected with the organization of motor command in groups. Resistance to fatigue during 45 rhythmic contractions of knee extensors increased after medium intensity training without relaxation and did not change after training of two other types. Three training regimes affected the size of trained muscles in different ways. In HI-group an increase of size for muscle fibers II was noticeably higher than for MF I. In MI-group the increases of size for MF of both types were similar, whereas after low intensity training the...
SUPPLEMENTAL TRAINING TO IMPROVE DANCE TECHNIQUE: THE EXAMPLE OF FRONTAL FALL SKILL

Rodrigues, L., Carvalheiro, S.
Technical University of Lisbon-Faculty of Human Kinetics, Portugal

To improve technique and prevent injuries, dancers need to follow a conditioning program. This plane can balance strength and flexibility in order to prepare the bodies for classes, rehearsals and performances.

Dance classes are not enough to develop those qualities, because the learning process of dance technique takes of the time, developing patterns of coordination required for specific dance movements.

The ballet technique and other dance styles might contribute to muscular imbalances. We need good dance conditioning programs to complete the work in technique classes.

In this study we analysed the frontal fall, a skill of modern dance technique that requires strong arms and shoulder girdle muscles and strong trunk flexors. Dancers, particularly the female dancers, have many difficulties (fear, light wrist injuries, etc.) in performing this skill.

In most technique classes, lot of time is spent exercising the lower limbs and, to a lesser extent, the torso and upper limbs. The majority of dance students are not prepared to dive to the ground and support their bodies’ weight.

Twelve female dance students participated in the experiment, ranging in age from 19 to 24 years. All subjects were enrolled in dance classes for 1 hour and a half to 3 hours a day, four to five times a week.

To evaluate the arms and torso strength it was applied the Push-ups and Sit-ups tests. For the evaluation of shoulder and torso flexibility it was used the tests of back-scratch and trunk-lift.

The duration of the conditioning program was twenty minutes, three times a week during five weeks. It consisted of a five minutes warm-up period, ten minutes of coaching and five minutes to cool-down. In spite of the diversity of exercises, all focused on the muscles groups mentioned before (shoulder, arm and trunk).

Six parameters were considered to evaluate the skill before and after the conditioning program: forward projection of the trunk, elbows position, lower limbs position, movement fluidity, control of the body when contacts the ground, and evident effort.

Statistical analysis of data collected shows no significant difference between the two moments of evaluation of the frontal fall. Program duration might have been too short to achieve results. We are applying the same test during a longer period (8, 10, 12 weeks) and results will be presented later.

EFFECTS OF 8 WEEKS OF HEAVY RESISTANCE CIRCUIT TRAINING VS. TRADITIONAL STRENGTH TRAINING ON PHYSICAL PERFORMANCE AND BODY COMPOSITION: A PILOT STUDY

Alcaraz, P., Pérez-Gómez, J., Chavarrias, M.
Universidad Católica San Antonio de Murcia, Spain

INTRODUCTION: Circuit training effectively reduces the time devoted to strength training while allowing an adequate training volume to be achieved. Nonetheless, circuit training has traditionally been performed using relatively low loads for a relatively high number of repetitions, which is not conducive to maximal muscle size and strength gain. PURPOSE: To compare the effects of 8 wk of heavy resistance circuit training (HRC) vs. traditional strength training (TS) on physical performance parameters, metabolic response and body composition.

METHODS: Twelve healthy subjects with strength training experience were randomly assigned to a HRC (n=6) (22.2 ± 1.6 years; 71.1 ± 6.0 kg; 176.4 ± 3.0 cm) or to a TS (n=6) (22.5 ± 2.1 years; 72.7 ± 7.9 kg; 179.3 ± 5.6 cm). Training consisted of weight lifting 3 times a week during eight weeks. Prior to and at the end of the training program, maximum dynamic strength (1RM) on bench press and half squat exercises, peak power output in both exercises using resistances of 30%, 45%, 60%, 70%, and 80% of 1RM and body composition (DXA) were determined. In addition, maximum lactate (Lactmax) was obtained after a 30 s Wingate test. T-tests for dependent and independent samples were used (p<0.05).

RESULTS: There were no between-group differences. The data confirm that upper limb (UL) and lower limb (LL) 1RM significantly increased in both groups (HRC = 23.6 ± 15.1%, and 27.7 ± 16.8%, and TS = 15.0 ± 7.0% and 19.1 ± 8.0%, respectively). In addition, UL peak power at 30% and 45% of 1RM was significantly higher in post-test for the groups (HRC = 15.8 ± 14.2%, and 15.8 ± 14.5%, and TS = 11.5 ± 7.4% and 20.6 ± 18.4%, respectively), and significantly higher at 70% of 1RM in TS group (17.3 ± 14.4%), while LL peak power was only increased significantly at 45% of 1RM (34.2 ± 24.0%) in HRC group. Lactmax was significantly higher after the training in the HRC group (HRC = 15.4 ± 10.8% vs. TS = 7.82 ± 10.6%). Regarding body composition, significant increases were found in the total body area, and a tendency to signification (p = 0.054) was established in the total lean mass in TS (3.6 ± 3.2%). CONCLUSION: The HRC and TS were effective methods to improve 1RM and peak power output, the metabolic response was greater in the HRC while the TS seemed to be more appropriate than HRC for enhancing lean mass.

PLYOMETRIC TRAINING AND VERTICAL JUMP HEIGHT PERFORMANCE: A META-ANALYSIS

Saez-Saez de Villareal, E., Kellis, E., Izquierdo, M.
University Pablo de Olavide, Aristotle University of Thessaloniki; Research, Studies and Sport Medicine Center, Government of Navarra, Spain

It is commonly accepted that plyometric training improves vertical jump height (VJH). However, the effectiveness of plyometric training depends on various factors. A meta-analysis of 56 studies with a total of 22% size effects (ES) was carried out to analyze the role of various factors on the effects of plyometric training on VJH performance. The inclusion criteria for the analysis were: a) studies using plyometric training programs for lower limb muscles b) studies employing true experimental design and valid and reliable measurements; c) studies including enough data to calculate ES. According to the results, subjects with more experience in sport obtained greater enhancement in
vertical jump height performance (p<0.01) On the other hand, subjects in both good and bad physical condition benefit equally from plyometric work (p<0.05), although men obtain better power results than women following plyometric training (p<0.05). With relation to the variables of performance, training volume for more than 10 weeks and with more than 20 sessions, and to utilize high intensities programs with more than 50 jumps per session were the strategies that will maximize the probability to obtain significant greater improvements in performance (p<0.05). Other important conclusion was that in order to optimize jumping enhancement it would be recommended to combine different types of plyometrics (squat jump+countermovement jump+drop jump) compared to to utilize only one form (p<0.05) Although, better results are obtained with treatment in dry rather than in wet conditions, no extra benefits gained from doing plyometrics with added weight were found. These conclusions are essential for the strength and conditioning professional to consider the most appropriate plyometric training approach based on the fundamental movement patterns, technique, volume and intensity, energy system requirements, and potential injury analysis for a given sport.

EFFECTS OF WEIGHTLIFTING TRAINING ON KNEE MUSCLE CO-CONTRACTION AND VERTICAL JUMP POWER

Arabatzis, F., Kellis, E.
Aristotle University of Thessaloniki, Greece

Introduction: The efficient coordination of agonist and antagonist muscles is an important early training adaptation. However, little research has been conducted on the role of training on agonist and antagonist muscle interplay and power improvement. Weak antagonist muscles may limit speed of movement (1) consequently, strengthening them may increase training results (2). The purpose of this study was to examine the effects of 8-weeks Olympic weightlifting training on muscle co-contraction and vertical jump performance.

Methods: Nineteen males (age = 20.4 ± 2.6 years, height = 175.8 ± 5.3cm, mass = 71.9 ± 3.5kg) randomly divided into 2 groups, the Weight Lifting (WL), and the Control (C) groups performed a 8-week programme (3sessions / week, 4 sets of 5 exercises at 80-100% of 1 Repetition Maximum ). Participants performed 3 vertical jumps squat jump(SJ), countermovement jump (CMJ) and drop jump (DJ), from 20, 40, 60 cm, onto a force platform. Electromyographic (EMG) activity of rectus femoris (RF) and biceps femoris (BF). Signals were sampled at a frequency of 1000 Hz. Co-contraction index was assessed as the BF to RF EMG activity ratio (BF/RF).

Results: Analysis of variance with repeated measures showed that, maximum height significantly (p<0.05) improved in all jumps for the WL group. The WL group increased significantly concentric power during CMJ and DJ60cm and eccentric power in DJ60cm. The co-contraction ratio decreased significantly (p<0.05) during the eccentric phase of CMJ and DJs. The results indicated significant changes in EMG activity of RF with simultaneous reduction of BF EMG activity, especially in eccentric phase of vertical jumps.

Discussion/conclusion: Our results confirmed the adequacy of Olympic weight lifting exercises in improving vertical jump performance. The mean power gains were accompanied by significant increases in neural activation of the agonist (RF) muscles recorded in both eccentric and concentric phases with significant reductions in the antagonistic co-activation during the eccentric phase of the vertical jump. The reduction of antagonistic muscle activity after power training may assist to reduce the braking phase duration about halfway the push off phase. In turn, this may increase resultant power. Olympic lifting exercises seem to be effective in improving jumping performance by reducing co-activation and improving muscle coordination.

THE EFFECTS OF WEIGHTED ROPE JUMP TRAINING ON STRENGTH PERFORMANCE IN ADOLESCENT VOLLEYBALL PLAYERS

Çolakolu, F., Karacaçan, S., Atalay Güzel, N., Baltac, G.
Gazi University, Turkey

Introduction: Rope jumping can be used to develop coordination of neuromuscular skills, muscular strength, and cardiovascular endurance. The aim of this study was to investigate the effect of a 12-week rope jumping and weighted rope jumping exercise programme on body composition and strength performance of female adolescent volleyball players.

Method: Twenty-six female volleyball players (age:14.66±1.16yrs) who had at least 2 years volleyball experience were recruited to participate in the study and were divided into there groups. Group 1 took on the weighted rope jumping (WRJ;n =8) diet as well as volleyball training, Group 2 on rope jumping (RJ;n=9) diet as well as volleyball training and Group 3, the control (C;n=7), participated only volleyball training. The exercise sessions were carried out 3 times each week for 12 weeks. Percentage body fat and subsequent fat free mass were estimated using Sloan and Weir’s equation. The hand grip strength of the subjects was measured by using Takei Grip-D trade mark hand dynamometer. Sit-ups and push-ups for 30 s for endurance and standing long jump, Sergeant Jump, and medicine ball javelin tests for lower and upper extremity muscular strength were applied to the subjects as described before.3 The effects of these exercise programs on subjects’ performance on the body composition and strength were analyzed with Kruskal-Wallis test.

Results: There was not a considerable change in the body weight among three groups exercising rope jumping. There was a decrease of the body fat between WRJ and RJ groups (p<0.01). The values of WRJ group were highly increased for the mean of sit-ups, standing long jump and the values of throwing the ball to the front part with two hands (p<0.01). There was a significant difference in the values of push-up, right hand grip strength at the end of training both two groups. Moreover, a considerable gap was determined between values of WRJ and C groups for left hand grip strength (p<0.01).

Discussion / Conclusions: Hong4investigated the effect of 8-week rope jumping training program on the development of neuromuscular coordination. It was determined that the rope jumping increased the neuromuscular coordination at a meaningful level (p<0.01). In this study a group doing exercises for 12-week programme with weighted rope would be gained a considerable power. The results indicate that a weighted rope jumping exercise programme has the potential to improve shoulder performance in a number of muscle strength and functional activities in volleyball players.

REMOTE COACHING
Baca, A., Kornfeind, P.
University of Vienna, Austria

A system architecture for monitoring, transmitting and processing performance data in sport is proposed. Sensors acquire the relevant performance data, the digitized signals are transmitted to a mobile client over a wireless interface (Bluetooth, ANT) and from this sent to an internet server. Coaches and sports scientists may thus give fast feedback not only at the training site but also from remote locations.

In more detail, physical and physiological values (e.g. force, acceleration, pressure, heart rate, breathing rate) are collected from the athlete with appropriate sensors. The produced analog signals are then digitized using a µC (Microchip PIC) with integrated ADCs (analog/digital converters). After preprocessing the signals (offset, scaling, filtering) either a Bluetooth or an ANT module is used to establish a connection between the measurement device(s) and a mobile client (e.g. PDA, Smartphone) in order to transfer the data (serial data stream). On the mobile device an embedded RichClientPlatform Application (eRCP) handles the Bluetooth communication to the sensors and the data storage process. Depending on the connection status (offline/online) the captured data are buffered either temporary local or transmitted directly to the server database (DB2everyplace). Possible communication profiles for the internet connection are GPRS, UMTS, and if available also WLAN.

Basically, the framework described above allows to monitor physical performance parameters of athletes and, moreover, to use the bidirectional route to positively affect the training process. Coaches, athletes and sports scientists (e.g. from the areas of exercise physiology or biomechanics) should be able to use this system not only at the training site but also from remote locations. It is not necessary to have a continuous internet connection during exercising. In case of interruptions the data will be buffered locally and sent later.

The different components of the system are currently developed in parallel. Upon availability of the complete system, coaches and sports scientists (experts) will be in a position to give rapid feedback to athletes during training (online training sessions) from any remote location having internet access. Athletes may easily compare their performance to others or put it in relation to norm profiles during exercising. Information exchange between athletes could be facilitated. Moreover, the system could be applied for training documentation purposes and as a tool to illustrate media presentations.
Results of various studies will be presented. In cross-sectional designs opposite stimuli conditions (high- and zero-load) at high level of hypoxic or mechanical stimulation, often is so low and the intra-group variability is so high traditional statistical testing cannot indicate the magnitude of effects that can be attributed to known physiological mechanisms, such as vessel degradation and/or formation after pre-adaptation. In groups of low level of performance, i.e. pre-adaptation, indicate a variety of subtle physiological responses that can be in-line with traditional physiological interpretation or are completely contradictory. This result is similar to those groups of low level of performance. In longitudinal studies the magnitude of effects that can be attributed to known physiological mechanisms, such as vessel degradation and/or formation after hypoxic or mechanical stimulation, often is so low and the intra-group variability is so high traditional statistical testing cannot indicate significant results.

Summary

Physiological models that lead to physiological pathways in the sense of multiple cause-effect chains are so complex that the attempt of an empirical verification of hypotheses normally is only possible under extremely controlled situation with homogenous groups of subjects at a low level of pre-adaptation. In groups of high-level pre-adaptation the magnitude of the stimuli often is too low, the time-course of effects normally is so inhomogenous and the individuality of the response is so high that statistically significant results are rare.

**Summary**

Physiological models that lead to physiological pathways in the sense of multiple cause-effect chains are so complex that the attempt of an empirical verification of hypotheses normally is only possible under extremely controlled situation with homogenous groups of subjects at a low level of pre-adaptation. In groups of high-level pre-adaptation the magnitude of the stimuli often is too low, the time-course of effects normally is so inhomogenous and the individuality of the response is so high that statistically significant results are rare.
TESTING AND MONITORING TECHNIQUES TO DETERMINE INDIVIDUAL PHYSIOLOGICAL ADAPTATIONS AND ACUTE RESPONSIVENESS TO TRAINING IN ELITE ATHLETES

Smith, D.
University of Calgary, Canada

Athletic excellence has been defined as the ability to maintain technical excellence, at speed, under pressure and when fatigued (adapted from Goldsmith, 2003). An analysis of the performance gap should include a performance technical analysis, also recognizing that the continuum of performance from optimal to under-performance is influenced by the competitive schedule and sequence of training on physiological, technical, psychological, tactical and health factors. Testing - the measurement of chronic structural and functional adaptations to training and monitoring techniques measuring acute functional responses to exercise provide tools for predicting and assessing stimuli effects. Outcome variables should be known to impact performance, be reliable and sensitive to training. Furthermore, test selection including submaximal, incremental, constant load, time-trial, and/or maximal tests can impact the timing of testing and the psychological effect on the athlete and coach. Thus regular physiological testing, anthropometric and nutrition assessments should be programmed into the Yearly Training Plan. A profile may be constructed of specific and non-specific tests establishing a performance time curve from short to medium duration including a 4 to 5 min exhaustive test together with a maximal lactate steady state evaluation. Monitoring techniques including blood profile, heart rate variability, orthostatic response and heart rate and lactate measures within a training set provide time-sensitive functional response data to the coach that should be evaluated against the sequence of training undertaken. Sport scientists conduct many different tests but monitoring/t test selection, timing, interpretation and action steps in conjunction with the coach are the keys to success.

Invited symposia (IS)

IS-PM08 Intermittent hypoxia for the improvement of performance

DOES INTERMITTENT HYPOXIA IMPROVE PERFORMANCE AT SEA LEVEL?

Bärtsch, P.
Div. of Sports Medicine, Germany

Two modalities of applying hypoxia at rest are reviewed in this overview. Intermittent hypoxic exposure (IHE), which consists of breathing hypoxic air for 5 - 6 minutes alternating with breathing room air for 4 - 5 minutes during sessions lasting 60 - 90 minutes, and prolonged hypoxic exposure (PHE) to normobaric or hypobaric hypoxia over up to 3 hours per day. The level of normobaric hypoxia used with IHE is usually in the range of 12 - 10 % O2, corresponding to an altitude of about 4000 - 6000 m. Normobaric or hypobaric hypoxia in studies applying PHE corresponds to altitudes of 4000 - 5500 m. Five of 6 controlled studies applying IHE and all 4 well controlled studies using PHE did not show a significant improvement with either modality of hypoxic exposure for aerobic or anaerobic performance at sea level after 14 - 20 sessions, with the exception of swimmers in whom there might be a slight improvement by PHE in combination with a subsequent tapering. There is no direct or indirect evidence that IHE or PHE induce any significant physiological changes that might be associated with improving athletic performance at sea level. Therefore, IHE and PHE cannot be recommended for preparation of competitions held at sea level.

IS INTERMITTENT HYPOXIA HELPFUL IN PREPARATION FOR HIGH ALTITUDE EXPOSURE?

Dehnert, C.
University of Heidelberg, Medical Clinic, Germany

Ascend to high altitude frequently causes high altitude illnesses. In most cases this is the harmless but unpleasant syndrome of acute mountain sickness (AMS). In some cases, however, harmful high altitude pulmonary (HAPE) or cerebral edema (HACE) may develop, particularly at altitudes above 4000 m. It has been shown that major determinants of the prevalence of these illnesses are individual susceptibility, absolute altitude reached, rate of ascent and the degree of pre-acclimatization. For a particular mountaineering trip the first two are given, whereas the last two can be modified. Reducing the rate of ascent is often not possible. Thus pre-acclimatization is often the only option to avoid or reduce severity of altitude illnesses. Since acclimatization at natural altitude is very time consuming and usually also expensive, attempts were made to acclimatize with repeated exposures to simulated altitude at rest or during exercise. Studies examining the effect of intermittent hypoxia at rest or during sleep used a variable time of exposure from 1.5 - 10 hours during 5 - 18 sessions at altitudes from 3000 - 6000 m. Reported results from these studies are inconsistent. While most of them showed an increased hypoxic ventilatory response only some also showed an increase in ventilation and/or an improvement of oxygenation during a subsequent hypoxic exposure. The fact that alterations in the hypoxic ventilatory response are still detectable several days to weeks after the end of the acclimatization period point to a carry over effect for ventilatory acclimatization. The few studies examining symptoms of AMS consistently report reduced severity of AMS. A weak point of almost all studies in this field is the low number of subjects and/or the lack of an adequate control group. Furthermore, most studies examining AMS were not performed in a double blind design and therefore results may be considerably biased by a placebo effect. The only placebo controlled double blind study exposing subjects for 8 hours over 14 nights at an average altitude of 2600 m showed significantly reduced severity of AMS during a 20 hour exposure to FiO2 of 12% equivalent to an altitude of 4500 m. Today, exercise during intermittent hypoxic exposure is offered by commercial institutions to enhance exercise performance at altitude and to reduce the incidence of AMS. While it has been demonstrated that performance at high altitude can be improved by training in hypoxia, the effect on AMS has not been evaluated until now. In summary, repeated exposures to hypoxia in preparation to high altitude sojourns can reduce AMS and training in hypoxia improves performance at high altitude. However, to evaluate the underlying mechanisms and the adequate dose of hypoxia further randomized double blinded studies are required.
DOES INTERMITTENT HYPOXIA HAVE BENEFITS FOR PATIENTS WITH CORONARY ARTERY DISEASE?

Levine, B.
Institute for Exercise and Environmental Medicine, Presbyterian Hospital of Dallas, United States

Intermittent hypoxia, such as induced by sleep apnea causes severe abnormalities of cardiovascular function, including prominent sympathetic activation, vasoconstriction, and sustained hypertension. These abnormalities lead to significant cardiovascular morbidity in patients who have spontaneous intermittent hypoxia at night, and raise caution regarding the use of intermittent protocols in patients, as well as healthy individuals like athletes. Moreover, although acute hypoxia generally causes systemic and coronary vasodilation to preserve oxygen delivery, recent evidence suggests that in patients with impaired endothelial function from atherosclerosis, paradoxical vasoconstriction may ensue. Conversely, in some models of intermittent hypoxia, activation of the hypoxia response pathways involving hypoxia inducible factor 1 may provide some protective effects against more profound hypoxia or ischemia, and small clinical studies suggest the possibility of improved myocardial perfusion and enhanced exercise performance. Overall, the available evidence suggests that intermittent hypoxia is more likely to harm than help patients with coronary heart disease, though careful study of mechanisms may reveal the opportunity for benefits under specific, carefully defined circumstances.

Invited symposia (IS)

IS-SH05 Gender and football

WOMEN’S FOOTBALL: A JOKE OR A SPORT TO BE TAKEN SERIOUSLY

Hjelm, J.
Department of Historical, Philosophical and Religious Studies, Sweden

According to many Swedish football experts, journalists and others, women’s football players at elite level are not even close to male football players as regards ball technique and game perception. To all appearances, there are similar views in many other countries where women’s football has been established. The chief aim of the study is examine the accuracy of this opinion, that is, is it correct that Swedish women’s football players at elite level often fail to perform when ball technique and game perception are put to the test. The study analysed how often the Swedish national team players failed in their actions in the Women’s World Cups of 2003 and 2007. Actions refers to passes, ball re-ceptions, dribbles, final shots and fixed situations. The men’s national team’s performance was corre-spondingly analysed in the Men’s World Cups of 2002 and 2006. The matches were analysed by means of video. The analysis of nearly 10,000 actions shows that there are differences but that these are relatively small and do not explain the very heavy and categorical criticism that is usually levelled against women’s football. The criticism is essentially due to the masculine coding of football and to female intrusion being perceived as a feminist provocation that hence has to be counteracted.

EMPOWERMENT AND DISCRIMINATION WITHIN ELITE FOOTBALL

Skogvang, B.
Hedmark University College, Norway

The purpose of this paper is to discuss gender, empowerment and discrimination within elite football in Norway. I will try to answer the research question: ‘How and why do elite players of both genders experience both empowerment and discrimination within elite football in Norway?’ This is a part of the project ‘Elit Football a Field of Changes’, where I have done observations in international championships, observations of practices, meetings, and matches in three elite football clubs through a year, plus interviews with 22 players (11 of each sex) and eight coaches in women’s and men’s football. Both women’s and men’s football have developed significantly during the last 25 years, and Norway is one of the leading nations in terms of international successes in women’s football. One crucial part of this is the ‘Norwegian Model’ of development programme, where girls and boys follow the same model and practice together. In the study many similarities were found in the conditions of the men and the women: They experience the game itself as joyful and exiting because of the tough tackles, the team spirit and the joy of victory, and the social network and the friendships are also mentioned as crucial. However, much progress has been made, particular problems regarding the women’s game globally as well as locally concern the difficulties of attracting sponsors and media interest. I also found that women’s sexuality is questioned when they play football. At the same time it is easier to be a lesbian inside some football clubs, but more difficult for men to be gays inside elite football. A conclusion is that the heter-onormativity is weakened for lesbians, but not for gays. Bourdieu’s field theory with elite football as a sub-field was employed in this study. Another conclusion is that, it is ‘doxic’ and taken for granted both inside and outside the field of football that men’s football is better than women’s football, that gay men do not exist in side elite football, and some men still have ‘the symbolic power’ within the field of football, even if it is the largest organised sport for both women and men in Norway.

MARKETING WOMEN’S FOOTBALL IN GERMANY

Klein, ML.
Ruhr-University Bochum, Germany

During the past years, European women’s football experienced a considerable upswing (Hong & Mangan, 2003). In Germany, football has become one of or even the most popular women’s team sports. This positive development certainly was supported by the recent sporting success of the women’s national team (World Champion in 2003 and 2007). Actually Germany will host the next Women’s World Cup in 2011. Now Women’s football is for the first covered by the big media and benefits from increased promotion by the German Football Association, Deutscher Fußball-Bund (DFB). But this lasting success story cannot belie the fact that esp. the base for a long-term establishment and sustainable sporting development of women’s league football in Germany is by no means secured. Thus, a number
of clubs of the first division league, the Bundesliga, are struggling with structural and financial problems and are still far away from a professional management and marketing.

Those briefly outlined development prospects and problems of women's football in Germany are studied in detail in an empirical research project. Based on a general economic market model of team sports (Hübl, Peters & Swieter, 2002), the key markets and demand groups, respectively, of the Bundesliga clubs are analysed. The media, sponsorship, attendance and merchandising, in addition, the external organisational network of the league (support by the DFB) as well as the clubs internal organisational and marketing structure is examined.

As to the data sources used in this research, association and club data, special periodicals on women's football, internet sites of the clubs, press releases etc. are analysed, quantitatively and qualitatively. In addition case studies of selected Bundesliga clubs enable a deeper look at marketing praxis. Structured interviews have been conducted with executives of 7 out of 12 premier league clubs and of the responsible association DFB. Furthermore, a questioning of totally 2.680 spectators of women's football games in 2007 gives information about the socio-demographic characteristics of the audiences, their motives and views of women's football.

Results of this study are: Marketing women's football in Germany, today, and in the running of the 2011 Women's World Cup, is going to be easier than in former times. But there remain handicaps in a male-dominated team sport market. Also, successful marketing is much more difficult for women's football clubs than it is for the German national team, for instance, because the league and individual clubs are simply not known well enough. A major problem is the huge differential both in sporting talent and economic base between the clubs.

OP-HF05 Health and Fitness 5 - Children

THE INFLUENCE OF MATURATION ON DAILY PHYSICAL ACTIVITY OF OBESE AND NON OBESE LISBON CHILDREN AGED BETWEEN 6 AND 11 YEARS OLD

Vieira, F., Fragoso, I., Barrigas, C., Bronzeado, M.
Technical University of Lisbon, Portugal

INTRODUCTION

Obese and non obese children show different patterns of daily activities. Most of the studies related with overweight and obesity and time spent on domestic tasks, leisure activities, organized and non organized sports do not take into account the effect of maturation. The aim of this study was to analyze if obese and non obese Lisbon children have different patterns of physical activity and whether the time spent in different activities can be influenced by maturation variability.

METHODS

The sample was composed of 1843 children (976 girls and 867 boys) aged between 6 and 11 years. The anthropometric measures were obtained according to Fragoso and Vieira (2000), the maturation was estimated in accordance with Khamis-Roche (1994). The sample was divided into six groups according to BMI cut-off points proposed by Cole et al. (2000, 2007) and the physical activity was evaluated through a questionnaire. The physical activity variables were time spent on regular and non regular activities, sedentary activities (PC and TV) and domestic tasks, done in all week. The descriptive statistics and the multivariate ANOVA were generated by SPSS 15 for Windows. Gender, age and relative height were used as covariant variables. The level of significance was set at p ≤ 0.05.

RESULTS

The prevalence of overweight, between 6 to 11 years, was 13.7% for boys and 20.3% for girls. The correspondent obese prevalence was 8.4% and 6.9%. The studied groups showed some differences on time spent on total physical activity being the three thinness grades the more active ones. Additionally the most sedentary children are the thinnest and obese ones. When using relative height as covariant the time spent on sedentary and non sedentary activities decrease slightly on the obese group. The only variable influenced by relative height was watching TV during the weekend.

CONCLUSION

Apparently, as it is shown in this study, relative height (maturation) doesn't seem to interfere in time spent in physical activity. However, early mature development can have different origins and different morphological consequences meaning that some of the children who are early mature spent more time in activity but some others who are also early mature are fat and sedentary. This confound factor will be considered in a future study.

IS THE BMI DURING THE FIRST TWO YEARS OF LIFE ASSOCIATED WITH THE BMI BETWEEN 6 AND 12 YEARS OLD?

Barrigas, C., Fragoso, I., Vieira, F.
Faculty of Human Kinetics, Technical University of Lisbon, Portugal

Introduction

In the last decades, many investigators have concluded that childhood overweight is associated to adult obesity. The association between a precocious metabolic program induced by nutritional stimulus or adaptations experienced in uterus that influences birth-weight (BW), physiological and morphologic characteristics in adult life and obesity is not consensual. Some studies point to a direct association
between BW and fat-free mass (Singhal et al., 2003), others recognize a direct association between BW and adult obesity (Labayen et al., 2005), and even others document an association between growth velocity in the first weeks of life and obesity in adolescence (Deckelbaum & Williams, 2001). The aim of our study is to identify the association between BMI measured in different moments in infancy in a sample of Portuguese children.

Methods
Our sample was composed by 612 Portuguese school children (323 boys and 289 girls) aged 6 to 12 years, who were divided into 6 groups, according to BMI cut off points proposed by Cole et al. (2000, 2007). Weight and stature during the first two years of life were obtained by questionnaire. Each child’s most recent measure was collected according to ISAK (2006) procedures. The BMI was calculated in five moments (birth, 1 and 6 months, 1 and 2 years and present age) and were transformed in Z scores. The descriptive analysis and the tests of Spearman and Friedman were calculated using SPSS 16.0 for Windows. The significance level was set at p<0.05.

Results
We have not found differences in Z scores between the five moments in both sexes (p=0.506 for girls and p=0.432 for boys). However, we found a significant correlation between Cole’s classification at two years and at present age in both sexes (p=0.001 in girls and p=0.009 in boys).

Conclusions
Our results reveal a tendency for the maintenance along the life time, at least until 12 years old, of the relationship between weight and stature (BMI). We concluded that there is an association between BMI in the first two years of life and BMI in later infancy.

THE IMPORTANCE OF THE WAIST CIRCUMFERENCE IN THE METABOLIC SYNDROME AND PHYSICAL FITNESS IN 6 TO 15 YEAR-OLDS

University of Madeira, Portugal

Research evidence has showed a connection between central adiposity and an increased risk of metabolic disorders, morbidity, and mortality. Waist circumference (WC) has been identified as the best predictor of Metabolic Syndrome (MetS) in children and adolescents. The purposes of this study were: 1) to determine if there were significant differences between the subjects who presented the WC risk factor (WCrf) and those without that risk factor (non-WCrf) for all the other MetS components and physical fitness parameters, in boys and girls across 3 agegroups (6-9, 10-11, and 12-14 year-olds); 2) to estimate the risk in WCrf subjects of having MetS and being considered unfit.

Methods
Participants in this study were 1128 children and adolescents ranging from 6 to 15 years of age attending the public school system in the island of Madeira. Subjects were measured for anthropometric indicators (weight, height and waist circumference), metabolic parameters (blood pressure, triglycerides, glucose and C-HDL), and fitnessgram tests (curl-ups, push-ups and pacer-20m). WCrf was defined according to the classifications by Katzmarzick et al. (2004) and Maffeis et al. (2001). MetS diagnosis was done according to the criteria established by Cook et al. (2003).

Results:
Multivariate ANOVA showed significant effects for factors agegroup and WCrf in all the metabolic parameters (p< .05) but not sex. Significant effects for found for all 3 factors in the fitness tests (p< .05). Significant 2-way interactions were found for blood pressure and triglycerides, and no 3-way interaction was found.

Risk estimate of being unfit in the pacer test when presented the WCrf was 3.453 (ICC 95% 2.559-4.661), comparing with the non-WCrf.

Conclusions:
For all agegroups and sex, subjects with the WCrf had significantly higher scores in the other MetS components (lower for C-HDL) and lower scores in the fitness tests.

ANALYSIS OF THE INFLUENCE OF SEVERAL FACTORS RELATED TO THE BIO-Psycho-social HEALTH ON THE PHYSICAL ACTIVITY OF ADOLESCENTS IN MADRID

Cordente Martínez, C., García Soidán, P., Sillero Quintana, M., Stirling, J.
(1) Facultad de Ciencias de la Actividad Física y el Deporte-INEF (Universidad Politécnica de Madrid) (2) Facultad de Ciencias Sociales y de la Comunicación (Universidad de Vigo), Spain

An epidemiological study (1) for adolescent scholars between 13 and 17 years old from Madrid was made in order to know which variables are the most important determinants of the physical activity (PA). After obtaining written consent of the parents, anonymous forms were completed by a random sample of 266 boys and 288 girls. This sample was selected from 35 educative centres from 16 of the 21 districts on which the city of Madrid is divided.

284 13th ANNUAL CONGRESS OF THE EUROPEAN COLLEGE OF SPORT SCIENCE
A first exploratory analysis showed that several variables turned out to be associated with PA, namely: gender, age, socioeconomic status (SES), PA of parents and friends, scholastic performance (SPI), money availability (MA), tobacco (TC) and alcohol (AC) consumption and being overweight (OW).

After a logistic regression, it was found that the variables that had the greatest influence on the PA were as follows, in order of importance: gender, PA of the father, PA friends and OW. With these four variables, a model was developed to predict the PA of the adolescents of Madrid.

As a result of our observations the following series of proposals for the future were made. Girls and adolescents with lower SES should receive high-priority attention concerning their health-related habits. Parents should be encouraged to practise PA, since the latter proves to have a positive influence on their children. Nutritional education for children, adolescents and parents is necessary to avoid being OW and to change sedentary habits. Although we did not observe any relationship between the screen time (ST) and PA, ST seems to be a relevant variable due to the current proliferation of multimedia entertainment and the average ST for our sample (225 min/day ±135 for boys and 174 min/day ±109 for girls).

DETERMINANT FACTORS OF CARDIORESPIRATORY FITNESS IN CAUCASIAN AND AFRICAN PORTUGUESE ADOLESCENTS

Santos, D., Silva, A., Santa-Clara, H., Cristóvão, P., Sardinha, L.
Faculty of Human Kinetics, Portugal

Cardiorespiratory fitness is an important health indicator in aged-school children. The aim of the current study was to understand the effects of some variables, such as body composition, age, race and gender in maximal oxygen consumption (VO2max) in a racially diverse sample of Portuguese adolescents (Caucasians C) and African Portuguese (AP). The sample consisted of 266 adolescents, 12-18 years of age (112 boys (80 C and 32 AP) and 154 girls (109 C and 45 AP)). Percent body fat (%BF) was estimated by a hand-to-hand bio-electrical impedance device (BF 300, OMROM). Cardiorespiratory fitness was assessed by the shuttle test from the fitnessgram battery. Multiple regression modelling methods were used. The prevalence of normal weight and overweight/obesity in this sample was 80.8% and 19.2% respectively. The mean values of VO2max were 45.0+/-6.2 ml/kg/min, 45.6+/-6.3 ml/kg/min, 36.2+/-4.9 ml/kg/min, and 38.8+/-4.9 ml/kg/min, respectively for C boys, AP boys, C girls, and AP girls. Girls showed a lower VO2max and higher %BF compared with boys (p<0.05). Overall, there were no significant differences between C and AP, though AP girls showed higher values in cardiorespiratory fitness compared to their counterparts. The model developed to explain VO2max showed that %BF (ß=-0.003, p<0.001), age (ß=0.011, p<0.001), and the interactions of age x Caucasian (ß=-0.001, p<0.01) and age x female (ß =0.004, p<0.001) were significant predictors, presenting a negative association with cardiorespiratory fitness. These results suggest that adolescents with higher adiposity, older Caucasians and older girls have lower cardiorespiratory fitness. The data seems to highlight the importance of interventions in promoting physical fitness in schools throughout the ages, taking into account the impact of determinant factors, such as race and gender.

PHYSICAL ACTIVITY IN PRESCHOOL CHILDREN - A PILOT STUDY

Vale, S., Silva, P., Santos, R., Mota, J.
Faculty of Sports - University of Porto, Portugal

Purpose: The aims of this study were (i) to determine Physical Activity (PA) patterns in preschool children with accelerometry in between gender and, (ii) to analyse discrepancy in the PA patterns using different epochs.

Methods: 45 Portuguese preschool children (25 girls, 20 boys) between the ages of 3 and 5 participated in the pilot study regarding PA patterns in preschool children. PA was assessed with accelerometers (MTI actigraph) during the school hours, for five consecutive days. Epochs were set at 5 seconds. PA was expressed as mean counts per minute during 5 days of MVPA, 95% CI: 23.11 - 30.33 for girls vs mean=29.69 counts per minute during 5 days of MVPA, 95% CI: 25.01-34.37 for boys albeit without statistical significance (p>0.05). The same tendency occurred with a 60 seconds epoch (mean=9.42 counts per minute during 5 days of MVPA, 95% CI: 6.33 - 12.50 for girls vs mean=12.33 counts per minute during 5 days of MVPA, 95% CI: 7.70 -16.96 for boys; p>0.05). In girls as well as in boys the average counts per minute of MVPA was much higher with a 5 seconds epoch than with a 60 seconds epoch (p<0.001).

Results: With a 5 seconds epoch, girls were, on average, less active than boys (mean=26.72 counts per minute during 5 days of MVPA, 95% CI: 23.11 - 30.33 for girls vs mean=29.69 counts per minute during 5 days of MVPA, 95% CI: 25.01-34.37 for boys) although without statistical significance (p>0.05). The same tendency occurred with a 60 seconds epoch (mean=9.42 counts per minute during 5 days of MVPA, 95% CI: 6.33 - 12.50 for girls vs mean=12.33 counts per minute during 5 days of MVPA, 95% CI: 7.70 -16.96 for boys; p>0.05). In girls as well as in boys the average counts per minute of MVPA was much higher with a 5 seconds epoch than with a 60 seconds epoch (p<0.001).

Conclusions: In Preschool Children gender differences in mean counts per minute during 5 days of MVPA were not significant. The use of an epoch of 60 seconds, compared to an epoch of 5 seconds, underestimated MVPA, in this children.
LIFETIME PARTICIPATION IN PHYSICAL ACTIVITY: DOES IT PREDICT EXERCISE ADHERENCE DURING BEHAVIORAL OBESITY TREATMENT IN WOMEN?

Carraça, E., Teixeira, P., Silva, M., Vieira, P., Castro, M., Coutinho, S., Santos, T., Sardinha, L.

Faculty of Human Movement, Technical University of Lisbon, Portugal

Purpose: To analyze the association between history of participation in physical activity (PA) and adherence to PA/exercise recommendations during a 12-month behavioral weight management intervention in women. To our knowledge, this is the first study to investigate this topic.

Methods: At baseline, 255 women (137.5 ± 21.7 yr, 31.6 ± 4.2 kg/m²) were randomly assigned to intervention (IG) or control groups. The IG participated in a 12-month weight management program seeking to improve diet and nutrition and increase physical activity. Controls received a general health education curriculum. At baseline, participants completed a PA and exercise history questionnaire. Past activity was categorized by exercise intensity (light, moderate, vigorous) and life period (infancy, adolescence, adulthood), and quantified in min/yr per category. Exercise adherence at the end of the weight management program was assessed with the 7-day PAR interview. Associations between PA history and self-reported current activity were analyzed with correlation/regression analyses and comparing activity level categories (± 150 min/wk of moderate/vigorous PA).

Results: In general, higher levels of total lifetime (p=0.001), total adult (p=0.002) and total vigorous PA (p=0.001) were associated with moderate/intense PA after the obesity treatment program. Adult vigorous PA was also a predictor of higher PA adherence at 12 months, for the whole sample (p=0.026). In the IG, only participants with higher levels of adult PA showed greater adherence to PA at program’s end (p=0.02). For controls, moderate/intense PA levels were predicted by previous PA experiences, namely total PA (p=0.019), adult PA (p=0.018), and total and infant vigorous PA (p=0.012 and p=0.005). Comparing PA categories, significant differences were observed for the total sample and for both participation groups. The active group reported more total (ES=0.40; p=0.012) and adult (ES=0.40; p=0.017) PA in the IG, active participants after the program reported approximately more 662 min/yr of adult PA (p=0.044) than the insufficiently active. Active controls reported having engaged in about 1000 min/yr more of adult PA than their counterparts (p=0.018). After adjusting for the intervention group, regression analyses showed that adult PA predicted greater adherence to moderate/intense PA during the intervention (B=0.21; p=0.014).

Conclusions: Results suggest a history of participation in exercise and physical activities may positively predict exercise adherence during weight management, a critical target of most interventions. This is especially true for recent (adult) PA and more vigorous past exercise experiences. Lifetime participation in physical activities should be evaluated and considered by professionals in the field, prior to initiating weight loss treatment.

CAN DIFFERENCES IN MOTOR PHYSICAL FITNESS (EUROFIT) BETWEEN OBSESE AND NON-OBSESE CHILDREN BE USED TO DESIGN MORE EFFECTIVE INTERVENTIONS TO INCREASE PHYSICAL FITNESS IN EARLY SCHOOL AGE OBSESE CHILDREN

Zinzen, E., Begyn, K., Watthly, C., Luyten, R., Gies, I., De Schepper, J., Clarys, P.

Vrije Universiteit Brussel, Belgium

Introduction

Obesity is an increasing health problem, starting already in primary school children. Promotion of physical activity programs at schools should take the motor performance of overweight children into account. Little is known about the variability in young children’s performance on tests of motor fitness. A study was designed to see whether the EUROFIT test battery (Adam et al., 1988) can be used to initiate health related physical fitness programs in obese children.

Objectives

To determine whether the EUROFIT Test Battery for children of 12-18 years old is reliable for testing children between 6 and 12 years of age and to determine differences in the motor physical fitness between obese and non obese children.

Material and Procedure

A randomised control group (N=42) was constructed for the obese children (patients) group (N=179). These controls were matched according to age and gender. The reliability of the EUROFIT test for children between 6 and 12 years old has been tested by a test retest with one week interval on the control group. Standard statistics (a.o. 1-tests) were used for determining reliability and differences between the experimental groups. The significance level for all tests was set on 5%.

Results and conclusions

The Eurofit test showed to be reasonable reliable. At retesting a learning effect could be noticed for plate-tapping, handgrip strength and sit-ups. The feasibility of the flamingo balance test and bent arm hang test was found to be very low in the experimental group. Respectively 62.1% and 80.5% of the children were unable to perform this tests.

The obese subjects scored significantly worse for all test components requiring propulsion or lifting of the body (standing broad jump, sit-up, bent-arm hang and the speed shuttle run). Obese children had significantly higher scores for the handgrip strength test and similar scores on the components of flexibility (sit & reach) and speed and coordination of the limbs (plate tapping). Results are in line with the study of Deforche et al. (2003).

As to bring obese children to more physical activity, it is suggested to avoid bodyweight bearing exercises in the beginning of physical activity interventions. Obese children will experience more success with exercises emphasizing their static strength and speed of limb movements. An adaptation of the flamingo balance test and bent arm hang tests are required for the use in the young age group, given their low feasibility scores.

SHORT-TERM IMPACT OF A MODERATE INTEGRATED WEIGHT LOSS PROGRAM ON COMORBID OBESE SUBJECTS AND ITS EFFECT ON WEIGHT LOSS MAINTENANCE AND EXERCISE ADHERENCE

Galvani, C., Medelli, J., Annoni, I., Magni, S., Mondoni, M., Faina, M.

Motor Science, 2Unité de Biologie de l’Effort et de Médecine du Sport; 3Istituto di medicina e scienza dello sport, Italy

Epidemiologic researches show an increasing percentage of overweight and obese subjects in the population. Obesity is often associated with many comorbidities. The American College of Sports Medicine recommends that the combination of reductions in energy intake and increases in energy expenditure, through structured exercise and other forms of physical activity, should be a component of weight loss intervention programs (WLP). There is also evidence that including behavioural principles within a WLP improves long-term outcomes. The aim of this study was to analyse the short-term results of an integrated WLP on body composition, physiological and health related parameters on a comorbid obese population, and to evaluate the results of the WLP on long-term weight loss maintenance and exercise adherence.

22 severely obese subjects (age, 40.3±6.48 yr; BMI, 43.37±6.03 kg/m²) followed a 3 weeks WLP composed by: an energy intake reduction, nutritional and psychological counselling and a tailored PA program (5 training sessions/week). PA program intensity ranged between 40 and 50% of VO2max for 40 minutes of cardiovascular exercises and between 40 and 60% of IRM for 1x10 strength exercises for different muscle groups. Before and after the intervention period a body composition analysis with bioimpedance methodology, a sub-maximal indirect test to estimate maximal oxygen consumption (VO2max) and a maximal indirect test to calculate maximal strength (IRM) were carried out. Framingham score was used to estimate health related parameters modification. The follow up included telephonic interview to collect information about physical activity ratio (PAR) and body weight after 6 months (FU6m).
Effect of a Weight Management Program on Body Composition, Physical Fitness, and Metabolic Parameters in Korean Obese Children

Introduction
Childhood obesity is progressing at an alarming rate. Since most overweight children become overweight adults, this chronic condition may increase the likelihood of cardiovascular diseases in adulthood as a result of early establishment of risk factors for cardiovascular diseases. To reduce this major health issue, effective childhood interventions are essential.

Purpose
The purpose of the present study was to examine the effects of weight management program on body composition, physical fitness, and metabolic parameters in Korean obese children.

Methods
Thirty-eight obese children (body mass index (BMI) > 95th percentile for age and sex) were recruited and randomly assigned to either a control (n = 19) or weight management group (n = 19). The control group received weight management counseling, and the weight management group received organized program, including exercise (~6-7 METs, 70 minutes, 2x/week), dietary education, and life style modification counseling for 3 months.

Results
The following variables were improved significantly with 3-month organized weight management program (mean ±95% confidence interval in weight management vs. control): weight [-2.3 kg (-4.2 to -0.4) vs. +2.5 kg (+0.9 to +4.1)], BMI [-1.7 kg/m² (-2.5 to -0.9) vs. +0.5 kg/m² (-0.2 to +1.2)], % body fat [-3.9% (-5.2 to -2.6) vs. +2.2% (+0.8 to +3.6)], VO2max [+3.7 ml/kg/min (+1.1 to +6.3) vs. -0.2 ml/kg/min (-1.2 to +0.8)], handgrip strength (+1.7 kg (+0.6 to +2.8) vs. +0.2 kg (-0.5 to +0.9)], sit-ups [+2.1 times/30 sec (+0.4 to +3.8) vs. +0.3 times/30 sec (-1.0 to +1.6)], TC [-15.4 mg/dl (-27.4 to -3.4) vs. +2.5 mg/dl (-9.3 to +13.4)], LDL-C [-11.0 mg/dl (-29.4 to +7.3) vs. +3.89 mg/dl (-5.8 to +13.6)], HOMA-IR [-1.0 (-1.5 to -0.5) vs. +0.2 (+0.8 to +1.6)], and hs-CRP [-0.4 mg/L (-1.2 to +0.3) vs. +0.9 mg/L (+0.3 to +0.8)].

Conclusion
Organized weight management program used for this study had beneficial effects on body composition, physical fitness, and risk factors for cardiovascular diseases in Korean obese children. In view of the global childhood obesity epidemic, multiple approaches, such as exercise, nutrition, lifestyle modification, and education, should be the focus of strategies aimed at overcoming childhood obesity.

The Effects of Caffeine on Endurance Cycling Performance and Exogenous Carbohydrate Oxidation: A Dose-Response Study

Desbrow, B., Barrett, C., Minahan, C., Grant, G., Leveritt, M.

Griffith University, Australia

This study investigated the effects of a low and moderate caffeine dose on exogenous CHO oxidation and endurance exercise performance. Nine trained and familiarised male athletes (age 29.4 ± 4.5 years, mass 81.3 ± 10.8 kg, ht 183.8 ± 8.2 cm, peak O2 uptake (VO2 peak) 61.7 ± 4.8 ml/kg-1·min-1, values are mean ±SD) undertook 3 trials, with training and high CHO diet being controlled. One hour prior to exercise subjects ingested capsules containing placebo, 3 or 6 mg.kg-1 BW of caffeine. Trials consisted of 120 min steady-state (56 ± 11%) cycling at ~70% VO2peak, immediately followed by a 7 kJ.kg-1 BW time trial (TT). During exercise subjects were provided with fluids containing 14C glucose every 20min to determine exogenous CHO oxidation. No significant TT performance improvements were observed during caffeine containing trials (Placebo 30.2 ± 5.3, 3 mg.kg-1 BW 30.4 ± 3.4, 6 mg.kg-1 BW 29.6 ± 3.8. TT Time ±SD min±s). Furthermore, caffeine failed to significantly alter maximal exogenous CHO oxidation (maximal oxidation rates Placebo 0.95 ± 0.2, 3 mg.kg-1 BW 0.92 ± 0.2, 6 mg.kg-1 BW 0.96 ± 0.2 g.min-1). Low and moderate doses of caffeine have failed to improve endurance performance in fed, trained subjects.
LOW GLYCAEMIC INDEX OR LOAD DIETS FOR WEIGHT LOSS

Thomas, D., Elliott, E., Bour, L.
The University of Sydney, Australia

Aim The aim of this review was to assess the effects of low glycaemic index (GI) or low glycaemic load (GL) diets for weight loss. Methods Studies were identified through searches of The Cochrane Library, MEDLINE, EMBASE and CINAHL for randomised controlled trials (RCTs) comparing a low GI or low GL diet with a higher GI, higher GL diet or other diet (CI diet for weight loss. Two authors identified studies, assessed their quality and extracted data, including information on adverse effects. Results Six eligible RCTs (N=202) were identified. Interventions ranged from five weeks to six months with up to six months further follow-up. Decrease in body mass (weighted mean difference [WMD] -1.1 kg, 95% confidence interval [CI] -2.0 to -0.2; P < 0.05; n = 163), total fat mass (WMD -1.1 kg, 95% CI -1.9 to -0.4; P < 0.05; n = 147) and body mass index (BMI) (WMD -1.3, 95% CI -2.0 to -0.5; P < 0.05; n = 48) was greater with low GI or GL diets compared to CI diets. Decrease in total cholesterol was greater with low GI or GL diets compared to CI diets (WMD -0.22 mmol/L, 95% CI -0.43 to -0.02; P < 0.05), as was decrease in LDL-cholesterol (WMD -0.24 mmol/L, 95% CI -0.44 to -0.05, P < 0.05). No study reported adverse effects, mortality or quality of life data. Conclusion A clinically significant decrease in body mass, total fat mass and BMI was seen with low GI or GL diets compared to CI diets. Lowering the dietary glycaemic load promotes weight loss and improves lipid profiles.

THE EFFECT OF FLUID INGESTION ON INTERMITTENT-SPRINT PERFORMANCE AND PACING STRATEGIES IN THE HEAT

Rouse, M., Duffield, R.
Charles Sturt University, Australia

Fluid ingestion during exercise is commonly used due to the proposed reduction in cardiovascular and thermoregulatory loads and corresponding maintenance of exercise performance. However, minimal research has examined the influence of fluid ingestion on performance and pacing strategies during intermittent-sprint exercise in the heat. Nine male, club-standard rugby players completed a familiarisation session followed by two randomized testing sessions consisting of ingestion of fluid (F) or no fluid (NF). Participants were also advised of a third session to ensure they were blind to all sessions; however this third session was not completed. All participants were pre-hydrated with 500ml of water 1h prior to each testing session. Participants completed a 50min intermittent-sprint exercise protocol in warm conditions (31 ± 0.7°C) with a 3min break at 30 and 40min in which they consumed 250ml (water) or no fluid. The exercise protocol involved a 15 m maximal sprint each minute followed by sub-maximal, self-paced exercise in a shuttle run format at varying intensities (hard running, jogging, and walking) for the remainder of the minute. Performance was assessed with 15m sprint time, distance covered during sub-maximal bouts and pre- and post-exercise vertical jump and hand grip tests. Physiological measures of heart rate (HR), core temperature (Tcore), nude mass and blood parameters (La-, pH) plus perceptual ratings of perceived exertion (RPE), thermal stress and thirst were measured throughout the session. No significant differences (p>0.05) were present between conditions in 15 m sprint time or distance covered during the sub-maximal bouts. However, trends were evident with the difference between conditions for distance covered progressing to a 7% difference in the final period, which represents a 61m reduction in the NF trial. No significant differences were evident in the pre- and post-exercise vertical jump and hand grip tests. Physiological measures of HR, Tcore, blood parameters and nude mass showed no significant differences (p>0.05) between conditions at any stage of the protocol. RPE and thermal ratings were not different between conditions at any stage, however rating of thirst scale was significantly higher (p=0.02) post-exercise in the NF trial. These results indicate that fluid ingestion has minimal effect on intermittent-sprint performance in warm conditions less than 1h in duration. However, a progressive difference began to exist, suggesting larger differences between conditions may be evident with longer exercise durations. Further, the presence or knowledge of fluid availability may alter pacing strategies in intermittent-sprint exercise, as while minimal physiological differences were present between conditions, participants progressively reduced the amount of work performed in the NF trial.

THE EFFECT OF A CARBOHYDRATE MOUTH RINSE ON SIMULATED 40KM TIME-TRIAL PERFORMANCE IN ELITE MALE COMPETITIVE CYCLISTS

Cosgrave, C., Donne, B.
Trinity College Dublin, Ireland

Recently a novel study reported suggested a significant performance enhancing effect of a carbohydrate (CHO) mouth rinse during high intensity exercise of approximately 1-hour in duration (Carter et al., 2004). Subsequent CHO mouth rinse studies have produced conflicting results. The present study aimed to investigate the effect of a CHO mouth rinse (6.4% maltodextrin) on simulated self-paced 40km time-trial performance in elite cyclists. Endurance trained male racing cyclists (n=8; mean±SD: age 31±3yr, mass 77±8kg, BMI 24.7±2.2 kg.m-2, body fat 14±2%, VO2max 68±6mL.kg-1min-1 and load at TLac 275±30W) participated in this study and were required to make five visits to the laboratory. The first visit consisted of a medical examination, a graded incremental test to volitional exhaustion (initial load 120W, increment 40 W every 3 min) and a 10km familiarisation session on a standard racing bike mounted on a fluid filled turbo-trainer, cycling performance data were continuously monitored using the SRM system. During subsequent visits cyclists performed simulated self-paced 40km time-trial separated by 3 to 7 days using double-blind, randomised design incorporating two placebo and two CHO mouth rinse trials (10mL mouth rinse for 10s every 5 km), during time trials the distance completed was the only data visible to the cyclist. Time, power output, heart rate, blood glucose and lactate were recorded at 5 km intervals. Group data across treatment and distance were analysed using 2-way repeated measures ANOVA and P<0.05 inferred statistical significance. A small, non-significant decrease in 40 km time to completion was noted comparing CHO and placebo mouth rinse trials (74.6±4.1 vs. 76.0±3.3 min, P=0.104). However the calculated 95% limits of agreement (95%LOA) from repeated placebo and CHO mouth rinse trials were -5.5 to 5.2 and -3.7 to 7.0 min, respectively, and identified wide variability within each repeated test arm. These 95%LOA were large in comparison with the mean time difference detected between test arms (7±1.4 min). Overall no significant differences were recorded comparing power output (P=0.13), heart rate, metabolic data, blood lactate or glucose concentrations across treatment. For all assessed variables the variation within was greater than variation between trials. Due to high intra-trial variation, the findings of Carter et al. (2004) are not supported. In conclusion, CHO mouth rinse appears to have no beneficial or ergogenic effect on performance time or physiological variables during exercise of this nature. More research into CHO mouth-rinse investigating postulated ergogenic effects are warranted. Future studies should ensure that the most appropriate, reliable
EFFECT OF HIGH AND LOW GLYCEMIC INDEX RECOVERY DIETS ON SKELETAL MUSCLE SUBSTRATE STORAGE AND UTILISATION DURING SUBSEQUENT EXERCISE

Stevenson, E., Thelwell, P., Thomas, K., Trenell, M.
Northumbria University, United Kingdom

BACKGROUND AND AIM: The glycemic index (GI) of carbohydrates consumed during the post-exercise recovery period significantly alters substrate utilisation during subsequent exercise (Stevenson et al., 2005). We have recently reported that consumption of high GI carbohydrates during recovery reduces FFA availability and increases reliance on intra-myocellular triglyceride as a substrate source during moderate intensity exercise (Trenell et al., 2007). It is unclear whether muscle glycogen utilisation is altered as a result of this change in muscle lipid metabolism. The purpose of the present study was to investigate the effect of high and low GI recovery diets on muscle glycogen and lipid utilisation during subsequent exercise.

METHODS: Nine male endurance trained cyclists (age 33.0 ± 6.9 yrs, mass 76.3 ± 7.0 kg, VO2max 61.5 ± 5.0 ml/kg/min) participated in two trials in a randomised cross-over design. Subjects completed a 90 min cycle at 70% VO2max and were then provided with a high GI (GI = 73) or low GI (GI = 35) diet to be consumed over the following 12h. Carbohydrate was provided at 8 g/kg body mass with 11% protein and 17% fat content. The following day after a 10 hour fast, the 90 min cycle was repeated and metabolic parameters measured. 1H and 13C Magnetic resonance spectroscopy were used to evaluate intra-myocellular triglyceride and glycogen content of the vastus lateralis before and after exercise. Blood samples were collected at 15 min intervals throughout exercise. Substrate oxidation was calculated from expired air samples.

RESULTS: There were no differences in the metabolic responses to exercise on Day 1. The 90 min cycle on Day 2 resulted in a greater reduction in intra-myocellular triglyceride in the high GI trial than the low GI trial (P < 0.05). There were no differences in muscle glycogen utilisation between trials. FFA concentrations were higher throughout exercise following the low GI diet compared to the high GI diet (P < 0.05). There were no differences in glucose, lactate or insulin concentrations during exercise between trials.

CONCLUSION: The results of this study support previous findings that consumption of high GI carbohydrates in recovery from exercise reduce FFA availability during exercise and increase reliance on intra-myocellular triglyceride as a substrate source during moderate intensity exercise. The GI of carbohydrates consumed during a 24 h recovery period does not influence muscle glycogen utilisation during subsequent exercise.

Stevenson, E., C. Williams, and H. Bisce, The metabolic responses to high carbohydrate meals with different glycemic indices consumed during recovery from prolonged strenuous exercise.

EFFECT OF SHORT TERM LIPID SUPPLEMENTATION ON A 1-HOUR TIME-TRIAL CYCLING PERFORMANCE

Decombaz, J., Lecointre, V., Grathwohl, D., Pollien, P., Schmitt, J., Borrani, F.

Nestle Research Center, Nestle Ltd, Lausanne, 2nd Institute of Sports Sciences and Physical Education, Fac. of Social and Political Sciences, University of Lausanne, Switzerland

PURPOSE: A short term lipid supplemented diet that increases intramyocellular lipids (IMCL) 55% while allowing normal muscle glycogen loading was previously validated (1). The effect of this diet on endurance performance is presently assessed.

METHODS: Twenty-two trained male cyclists performed two simulated time trials (TT) in an open randomized crossover design. Subject selection at entry included a performance test (VO2max, Wmax) and TT familiarization. Two weeks later, the subjects performed a 2h submaximal exercise to deplete energy stores. This was followed by feeding one of 2 glycogen replenishment diets for 2.5 resting days (7 meals): a Twenty-two trained male cyclists performed two simulated time trials (TT) in an open randomized crossover design. METHODS: Twenty-two trained male cyclists performed two simulated time trials (TT) in an open randomized crossover design. Subject selection at entry included a performance test (VO2max, Wmax) and TT familiarization. Two weeks later, the subjects performed a 2h submaximal exercise to deplete energy stores. This was followed by feeding one of 2 glycogen replenishment diets for 2.5 resting days (7 meals): a high-carbohydrate low-fat diet (HC diet), or an identical diet that was fat supplemented during the last 4 meals only (HCF diet, total excess fat load ~280g). Macronutrient intake over the entire period was (protein, carbohydrate, fat; g/kg/d): 1.4, 7.4, 0.6 (HC, 39 kcal/kg/d) and 1.6, 7.3, 2.3 (HCF, 55 kcal/kg/d), respectively. The next morning, whole body fasting fat oxidation was measured by indirect calorimetry and reproducible endurance performance measures are used. Larger sample population and testing CHO mouth-rinse vs. placebo on multiple occasions will ensure results stand up to detailed statistical analysis.

MATRIX OF ANALYSIS FOR SPORTS TASKS; TAXONOMIC SURF MODEL

Moreira, M., Peixoto, C.
Technical University of Lisbon – Faculty of Human Kinetics, Portugal

Introduction
In an ecological approach, the ideal technique is difficult to define, being each time more accepted the necessity to characterize the environment, the performer and the task, to be able to identify the best performance.
Construct a sport activities matrix of analyzes from an established taxonomic framing of the activities aiming the improvement of techniques.

Methods
Sample was within Surf discipline in a competition flowing having 5 of the top 16 Portuguese surfers training together.
The study intended to develop a Matrix of Analysis for Sports Tasks (MAST), no matter the sports activity, based on the practise classification and the task analysis. Based on a qualitative method, studying the surf as the main activity, this was an interpretative study case.
The MAST was applied in four phases: taxonomy, tasks and context description, task analysis, teaching/performance strategies. Its application allows the activities’ characterization through the observation, surfer's opinions and bibliographical support. The data was crossed as an information data treatment.

Results
Surf is a discipline of surfing which is a sliding sports modality therefore a Nature sport.
Waves and surfboards are related to the context. The knowledge of the swell formation process allows the anticipation of the breaking waves (waves' components and waves' conditioners). As main surfboards' characteristics we have the format, the composition and the fins, being / associated to the quality of the surfboard.

With the tasks description, 9 groups, including several techniques, were found becoming possible the development of a diagram with the trajectories in the waves and the possible linkings between techniques.
Some characteristics aspects were found through the functional analysis that allowed a better understanding of the techniques.

Conclusions
The elements are classified by the challenges proposed to the practitioners and the taxonomy is constituted by the sport activities, group, modality and discipline. The structural analysis allowed to identify and to explain the inter task relationships linkings between groups of manoeuvres and intra task (relationships between manoeuvres of the same group). The understanding and learning of the manoeuvres must be from the terrestrial environmental to the aquatic one, from a stable context to an unstable one, from a plain surface to an inclined one. With the task analysis it is possible to perceive the relationship between manoeuvres and the sections of the wave; surfboards and the waves; manoeuvres and the technical level. The structural and the functional analysis allowed to find solutions for the learning of trampoline and skateboards because these last ones fit in sliding sports. MAST makes possible the development of strategies that benefit teaching/performance intervention.

PHYSICAL ACTIVITY, MOTOR COMPETENCE AND HEALTH STATUS OF CHILDREN IN DEPENDENCE OF SOCIAL STATUS

Holzweg, M., Ketelhut, K.
Humboldt University Berlin, Germany

Introduction
In the last years the health status of children in Germany declined and the number of psychologically conspicuous children also increased. According to the KIGGS study children from socially deprived areas are hit from this development the most (compare Opp et al., 2007). Holzweg (2006) and several other studies allocate a decline of the level of activity and the motor competence of young children in Germany (compare Woll, 2007 for an overview). In this study physical activity, motor competence and health status of children with different social backgrounds (privileged vs. deprived) are assessed.

Method
A sample of 172 3-5 year old children was included in this study. While 80 children lived in a deprived area 92 children lived in an affluent area. The children were testes with the KMS 3-6 and the MOT 4-6. Height, weight and Body Mass Index (BMI) were also assessed. In a questionnaire for the parents’ social status, activity level, television consumption, participation in sport clubs and sport activity of the family were assessed. The social status was collected by profession and income of both parents and according to the social structure atlas for Berlin. The analysis of the assessed data was carried out with SPSS 15 (ANOVA).

Results
Regarding coordination [SHI: F(3,9)=16.51, p<.05; eta²= .085], TBT: F(3,9)=14.28, p<.05; eta²=.075] and flexibility [F(3,9)=20.14, p<.05; eta²=.102] significant differences between the two groups could be shown. With the data of the questionnaire significant differences between the two groups relating to television consumption [F(3,9)=44.87, p<.05; eta²= .238], participation in sport clubs [F(3,9)=22.6, p<.05; eta²=.132], outdoor activities [F(3,9)=6.37, p<.05; eta²=.041], as well as sport activity of the family [F(3,9)=17.35, p<.05; eta²=.104] could be identified.

Discussion / Conclusions
The study showed that comparable to obesity and health status also motor competence is decisively influenced by the social status of the children. The results of this study additionally indicated differences of the level of activity in dependence of the social background. Therefore it seems to be necessary to offer affirmative intervention programmes especially in Kindergartens and Primary Schools in socially deprived areas.

References.
Participation in physical activity (PA) during childhood can help to reduce the onset of risk factors associated with ill health. Recommendations for healthy levels of PA for children have been established by the National Association for Sport and Physical Education (NASPE guidelines, 2004). Children should accumulate at least 60 min of moderate and vigorous PA on most if not all days of the week. Lack of information about Italian children has made it impossible to assess proportions of children meeting the recommendations. The aim of this study was to objectively measure PA behaviour in a sample of 8 to 12 year-old children in order to investigate if they fulfilled NASPE PA guidelines.

16 healthy children (age, 9.1±1.2 yr; BMI, 19.8±4.6 kg/m2; RMR, 4406.6±1758.6 kJoule/d; VO2max, 39.9±8.2 ml/kg/min) were monitored during a whole week in winter and in summer with a Actiheart (AH) monitor (Cambridge Neurotechnology, UK). The AH is directly attached to the chest with two standard ECG electrodes and it is able to measure acceleration, heart rate (HR), HR variability and ECG magnitude for objectively measuring PA and inferring time spent in sedentary or light (ISPA, <3 METS) to moderate (MPA, 3-6 METS) and vigorous (VPA, >6 METS) intensity. Data presented provide a minimum of four days of 10-h valid recording per week (the choice of 4 ensures that at least 1 weekend day is included).

Data analysed through the Branched model showed that children significantly exceeded NASPE guidelines of 60 min of moderate-to-vigorous PA (MVPA) both in winter (MVPA 143.4±67.9 min/day, p<0.001) and in summer (178.3±78.8 min/day, p<0.0001). However, a significant seasonal difference was detected especially for time spent in MPA (MPA: winter 132.2±62.8 min/day, summer 161.6±70.1 min/day, p<0.05). On the contrary, no significant differences appeared between weekly and weekend days (MVPA: weekly days 160.3±86 min/day, weekend days 161.4±86.7 min/day, p=ns). Besides, the between intensity comparison revealed a significant higher amount of time spent in moderate than in vigorous intensity (MPA 146.9±67.2 min/day, VPA 14.1±12.7 min/day, p<0.001).

The main finding of this study is that Actiheart data, taking intensity of activity into account, indicate that Italian young children significantly exceed the minimum activity standard of 60 min of accumulated MVPA per day. Although it is likely that all children should be encouraged to adopt an active lifestyle, it is unclear if 60 min of intermittent, accumulated PA are sufficient to gain health benefits or if it is favourable 60 min of sustained PA. Taking into account seasonal differences, a suggestion could be to increase physical education hours during school time.

Conclusions.

The main finding of this study is that Actiheart data, taking intensity of activity into account, indicate that Italian young children significantly exceed the minimum activity standard of 60 min of accumulated MVPA per day. Although it is likely that all children should be encouraged to adopt an active lifestyle, it is unclear if 60 min of intermittent, accumulated PA are sufficient to gain health benefits or if it is favourable 60 min of sustained PA. Taking into account seasonal differences, a suggestion could be to increase physical education hours during school time.

YOUTH SPORT PARTICIPATION AS BASIS FOR A PHYSICALLY ACTIVE LIFESTYLE AND HEALTH

Telama, R., Yang, X., Hirvensalo, M., Raitakari, O.
LIKES Research Institute, Finland

The aim of the study was to investigate the relationship of youth sport participation with adult physical activity and some selected health variables.

Methods. The data were obtained from the Cardiovascular Risk in Young Finns Study. The subjects of this study were 9-, 12-, 15- and 18-year-old girls and boys (N = 2200) who participated in base line measurements in 1980, and in follow-ups in 1983, 1986 and 2001. Participation in youth sport (sport club training sessions, sport competitions and persistent sport participation) was measured through a self-report questionnaire. To study the effect of persistent sport participation the subjects were divided into four groups on the basis of two subsequent measurements. Actives, who participated in both 1980 and 1983; Beginners who did not participate in 1980 but did in 1983; Drop Outs who participated in 1980 but not in 1983, Outsiders who participated neither in 1980 nor in 1983. Physical activity (PA) questions in adulthood concerned the frequency and intensity of PA, frequency and hours per week of intensive PA and participation in organised PA on the basis of which a Physical Activity Index (PAI) was formed. Measurement of health and lifestyle in adulthood included attention paid on health habits, BMI and sum of z-scores of following metabolic syndrome variables: insulin, triglycerides, HDL-C (inverted), glucose, systolic and diastolic BP and waist circumference.

Results. A regular and persistent participation in youth sport was significantly associated with high physical activity level in adulthood. The odds ratio (OR) for belonging to the most active tertile of PAI in adulthood was in females participating many times a week 6.0 (IC 2.4 - 15.1) and in males 5.1 (2.9 - 9.1) non participants being as reference. OR for Active sport participants was 4.2 (2.0 - 8.9) in females and 9.9 (5.0-19.3) in males Outsiders being as reference. Also participation in high level sport competitions increased the probability to be active in adulthood both in males, OR 3.3 (2.0 - 5.4) and in females, OR 3.5 (2.6 - 18.4) Outsiders being as reference. Those who participated more than once a week in sport club training sessions had higher probability to pay attention to their health habits in adulthood than non-participants, females’ OR 1.9 (1.1 - 3.3), and males’ OR 2.0 (1.3 - 3.0). The frequent participants also had higher probability for normal weight than non-participants among males, OR 1.9 (1.1 - 1.3) but not among females when adjusted for the youth BMI. Frequent sport participants had lower level in the sum of z-scores of metabolic variables than non participants among males (P>0.001) but not among females.

Conclusion. It is concluded that a frequent and persistent participation in youth sport is associated with a high physical activity level in adulthood and also with important health variables, especially among males.

PHYSICAL EDUCATION IN THE NATIONAL CURRICULUM STATEMENT OF SOUTH AFRICA: PERSPECTIVES OF TEACHERS

Van Deventer, K., Van Niekerk, E.
Stellenbosch University, South Africa

Educational transformation in South Africa not only brought about Curriculum 2005 and Life Orientation as a new Learning Area / Subject, but also major challenges, especially for Physical Education. In the previous dispensation, Life Orientation's constituents were perceived as being of minor importance by many educationists due to its non-examinable status creating many preconceptions about the Learning Area / Subject. Against this background, it was necessary to investigate Life Orientation teachers’ perspectives regarding the implemen-
tation of the Learning Area / Subject in Grades R-11. Two hundred and forty-eight (N=248) schools which consisted of n=124 primary and n=124 secondary schools were randomly selected in the Western Cape region of South Africa. A response rate of 63%. (N=157) was obtained. Summary statistics using frequency tables and histograms were utilised. Comparisons of ordinal variables were done using one-way variance of analysis (ANOVA) and the Kruskal-Wallis non-parametric test. The data was analysed with Statsoft Statistica 8.0 (2007). The results indicate that the Learning Outcome related to the Physical Education focus of Life Orientation in the General Education and Training (GET) Band and Further Education and Training (FET) Band is presented in the majority of schools. However, the fact that 60% of the schools do not have qualified Physical Education teachers at their disposal, hold certain implications for the status of Life Orientation in general and more specifically for the growth and development of the learners. Life Orientation is a compulsory offering for all learners in Grades R-12 since the 1 January 2008 and therefore it is recommended that in-service and pre-service education and training of teachers receive a high priority from the Department of Education and that Higher Education Institutions become more involved in different forms of training initiatives than is currently the case. The state and status of Physical Education in South African schools and the implication that it has for sport development among the youth have been a major concern for more than a decade.

Key words: Curriculum 2005; Outcomes-based Education, National Curriculum Statement; General Education and Training Band; Further Education and Training Band; Life Orientation; Physical Education; Teacher training; Teacher perspectives.

DANCE AND THE PHYSICAL EDUCATION STUDENT: COMPARISON BETWEEN PORTUGUESE AND FINNISH UNIVERSITY STUDENTS

Macara, A., Correia, S.
Faculdade de Motricidade Humana, UT Lisbon, Portugal

Introduction
Many authors (Lynch, 1991, Taylor & Taylor, 1995, Macara, 1997, Mayer, 1998, Nakra, 2000) indicate dance as a form of physical activity fundamental for the development of young people. This is due not only to the potential for the rhythmic and motor development, but also for the artistic and aesthetic education. Considering that both in Portugal and in Finland, Physical Education Teachers are supposed to include dance in their teaching programs, we tried to better understand the relation of the future physical teachers in two universities with different curricula, in countries with different teaching traditions in what concerns dance.

Methods
The participants serving as sample for this study were 3rd year Physical Education Students from the University of Jyväskylä, Finland (n= 48) and from the 3rd year of Faculdade de Motricidade Humana in the Technical University of Lisbon, Portugal (n=63). Using specifically designed questionnaires, we looked for the types of dance, with which the students identified the most, and their previous dance practice, before and after the study in the University. Descriptive statistics was used to characterise both groups.

Results and discussion
As results we found similarities between the two groups: in both countries the involvement with dance previously to the University is significantly larger in the female sub-groups. Also, in both countries street dance, such as hip-hop were the most practiced. Contrarily ball-room dance was much more practiced by Finish students than in Portugal. In conclusion in both countries we find that most students have never practiced any dance forms. Though they may have some dance in the curriculum, the interest for this activity is relatively low, especially in the male subgroups. This indicates the necessity to develop the teaching of some dance forms in the curricula of PE teachers, knowing that street dance is presently the most attractive dance form for both genders and in both countries.

TALENTED ATHLETES AND SCHOOL PERFORMANCE; A COMPARISON OVER 14 YEARS
Jonker, L., Efferink-Gemser, M., Visscher, C.
Center for Human Movement Sciences Groningen, University Medical Center Groningen, University of Groningen, Netherlands

Talented athletes and school have been subject of continues debate. It was assumed, for years, that top level sport may be negatively linked with school performance. Recent research has indicated that talented athletes perform well in school (Dexter, 1999, Durand-Bush & Salmela, 2002). It is not yet clear whether this transition is related to school facilities, increasing importance of sport performance or changes in the type of student athlete. The purpose of this study is to gain insight in the school performance of talented athletes in 1993 and 2007 in the 14-16 age-band.

A questionnaire was used to measure the school performance of 253 talented athletes in 1993 and 260 in 2007. All talented athletes participated in a sport selection. All 2007 talented athletes were part of a school with special facilities. School performance was measured by school level [i.e. pre vocational or pre university]. Whether athletes had difficulties combining sport and school was assessed by a combination of an objective standard and perceived school performance.

Stability in the national averages of 1993 and 2007 was observed (p>05). It was also found that 2007 talented athletes were more often present in pre university education (p<05), whereas regular youth was more often present in pre vocational education. Results indicated the same tendency for 1993 talented athletes. In addition, 2007 talented athletes were more often present in pre university education than 1993 talented athletes (p<05). No significant difference was found between 1993 and 2007 on difficulties combining sport and school (i.e. 48,8% vs 41,2%).
When compared to the national average, talented athletes in 2007 attend pre university education more often. It is assumed that talented athletes might be more focused, motivated and self-regulative. A higher percentage of the 2007 talented population participated in pre university education in comparison with 1993, whereas the percentages of regular youth showed stability. Since no difference is found on difficulties in combining sport and school between 1993 and 2007 (i.e. without vs with facilities) it appears relevant to investigate self-regulation (e.g. metacognition, motivation and behavior) of today's talented athletes. Self-regulation of performance might be a promising venue as research indicates that expert performance in sport may not only be attributable to innate physical characteristics and physical training but also depends on levels of self-regulation. Experts in sport as well as in school have been indicated to be more self-regulative (Ertmer & Newby, 1996; Cleary & Zimmerman, 2001). It might well be possible that talented athletes are capable of learning skills in sport and use it in school and vice versa.

AFFECTIVE RESPONSES DURING EXERCISE AND THEIR INFLUENCE ON FUTURE PARTICIPATION

Parfitt, G.
University of Exeter, United Kingdom

Purpose: Affective responses to exercise may be the first link in the chain between exercise and adherence. However, the progress of research in this area has been hampered by practical constraints (e.g. tracking individuals, controlling exercise intensity). This study extends the research by exploring the perceived impact of acute responses to either an imagined exercise experience at a prescribed high-intensity (HI) exercise session or a preferred self-selected (SS) intensity exercise session on future exercise participation.

Methods: Seventy volunteers (35 male, 35 female) took part in the study. Participants read (in a counter balanced order) 4 scripts that described two imaginary exercise sessions (one that was prescribed and one that was self-selected). The scripts either described the cues typically generated during exercise, or the cues generated following recovery. In the ‘during’ exercise scenarios, the cues are more extreme in the HI condition than the SS condition, where it is clear that the participant can alter their intensity to achieve a preferred level. After reading each script, participants completed measures of their rating of perceived exertion (RPE, Borg, 1998) and recorded their affect using the feeling scale (FS: Hardy and Rejeski, 1989). They then indicated to what extent the FS they had just recorded would influence their future participation and whether this would be in a positive or negative direction.

Results: As anticipated, and confirming the scenario manipulation, ANOVA indicated that the RPE responses were significantly higher for the ‘during’ HI script (M=16.4, SD=1.9) compared to the ‘during’ SS (M=12.8, SD=3.0) but that both decreased ‘post’ exercise (HI(M=11.9, SD=2.7, M=10.3, SD=2.7, respectively). FS was significantly lower in the ‘during’ HI (M=-0.29, SD=2.9) compared to the ‘during’ SS condition (M=-1.8, SD=-2.0) and became more positive in the recovery condition (M=1.36, SD=2.72, M=2.58, SD = 1.88, respectively). Preliminary analyses indicate that very positive or very negative FS responses were more likely to influence future participation (p<0.01). Further, the more negative the FS response the greater the negative influence, while positive FS responses were perceived to influence participation in a positive direction.

Conclusions: The results, although limited by the methodology selected, support the position that affect could be the first link in the chain to adherence. The data suggest that if the exercise experience leads to a large negative response then this will have a perceived negative effect on future exercise participation. However, a positive response, as experienced in the SS condition had the opposite effect.

POWER LAW DISTRIBUTIONS IN PATTERN DYNAMICS OF ATTACKER-DEFENDER DYADS IN RUGBY UNION: PHENOMENA IN A REGION OF SELF-ORGANISED CRITICALITY?

Passos, P., Araújo, D., Davids, K., Milho, J., Gouveia, L.
Lusófona University of Humanities and Technologies, Portugal

In the region of self-organised criticality (Bak, 1996) an interdependency of action between system components exists and slight changes in circumstances characterising near-neighbour interactions (i.e. attacker defender dyads in team games) can break the balance of equally poised options leading to sudden transitions in system order. In this region frequency of events (i.e. attackers attempting to pass defenders and defenders counterbalancing attackers’ actions) of differing magnitudes exhibits a power law distribution, in which smaller fluctuations arise more frequently than larger system changes such as phase transitions. The aim of this paper was to identify a power law distribution for the attacker-defender dyadic system in rugby union, suggesting that pattern forming dynamics observed in team sports is a phenomenon in a region of self-organizing criticality (SOC). In our analysis of typical (1 v 1) sub-phases of rugby union near the try line, videogrammetry captured players’ motion and TACTO 7.0 software digitized player positions (Passos et al., 2006). Power laws were calculated based on the rate of change of relative position between an attacker and defender. This power law displays a certain quantity N (i.e. frequency of changes in attacker-defender relative positioning) which can be expressed as a power of another quantity s (i.e. the magnitude of frequency of changes in attacker-defender relative positioning), in the following equation: log N=β-1·log s. Our analysis showed that three emergent patterns from dyadic system interactions (i.e. clean try, unsuccessful tackle, and effective tackle) revealed a power law distribution with exponents between 1.2 and 1.9. Adjustments in players’ relative positioning with higher magnitudes occurred less frequently than smaller adjustments. These findings suggested that pattern forming dynamics observed in attacker-defender dyads in rugby union exemplify the natural phenomenon of SOC. In this region the distribution of adjustments in players’ relative positioning approximated a straight line, exemplifying a power law in accordance with Bak’s (1996) underlying principle for system complexity. Players spontaneously adjusted their relative positions with information available in each specific performance setting, such as an opponent’s relative position. Required adjustments were scale free since there were no typical sizes of variations. We may conclude that attacker-defender dyads evolve in SOC regions signifying that players’ decisions and actions were governed by local emergent interactions rules rather than by outside agents or previously determined actions.

FORMATION OF PHYSIOLOGICAL PREPAREDNESS OF EXPERTS IN SPHERE OF PHYSICAL TRAINING AND SPORTS

Ershova, N., Vikhreva, S., Kholodilova, E.
Velikie Luki State Academy of Physical Education and Sports, Russia

Introduction. The problem of social adaptation of children-orphans and children who have remained without care of parents, is especially painful now for our society. For today the very actual is the purposeful psychological preparation of experts which will promote the most effective formation of the personality of junior pupils in the conditions of a boarding school.

Our research aims to form the psychological preparedness of experts in sphere of physical training and sports for work in boarding school.

Methods and subjects. 131 students aged 19-23 took part in the experiment.

The empirical methods were used: 1) express-questioning which has allowed to reveal: a) subjective opinion of respondents concerning with the level of the importance of the personal-professional skills which are necessary for the expert in sphere of physical training and sports for effective activity with the orphans (on a mark scale from 0 to 10; 0 - not significant skill, 10 - the most important professional skill); b) the respondents' level possessing of the given professional skills (on a mark scale from 0 to 10 points: 0 - it is not formed, 10 - it is completely formed); 2) the testing of real formed level of professionally important skills, and also level of social disadaptation of children-orphans of junior pupils; 3) the quantitative and qualitative analysis of the received data; 4) the correlation analysis (or statistical processing of results of research).

Results. The research was carried out in the boarding school. During the research the essence of professionally important skills, the features and the factors providing their development and display were studied, and also the conditions promoting effective formation of psychological preparedness of the expert were investigated; the degree of influence of professionally important skills on decreasing of social disadaptation children-orphans of junior pupils was established.

Our findings show that the high formed level such personal-professional skills as the empathy, stress-stability, tolerance, reflexivity, communicativeness, self-organization, objectivity, working capacity, creativity, emotional flexibility, affiliation makes the base of psychological preparedness of the expert of physical training and sports and has direct influence on the process of decrease of social disadaptation of children of junior pupils.

Conclusion. The development of professionally important skills is initial, very important and responsible stage of formation of psychological preparedness of the expert in sphere of physical training and sports for work in boarding school. The purposeful professional training of experts will provide faster adaptation of children-orphans in the conditions of a favorable psychological climate, will promote decrease in level of anxiety, aggression and vulnerability, correction of negative emotional displays and development of skills of positive social behavior.

PERCEIVED MEDIA INFLUENCE ON BODY IMAGE CONCERNS OF TURKISH ATHLETES

Asci, F., Hashemvarzi, S., Fallahmohammadi, Z., Dabidi, V.
BASKENT UNIVERSITY, Turkey

The purpose of this study was to investigate the influence of media on body image concerns (weight loss, weight gain and muscle size) of Turkish athletes. The study also aimed to examine the perceived pressure from media on body image concerns of athletes with regard to gender, sport experience and types of sport.

One hundred and six female (Mage = 18.5, SD= 3.8) and 197 male (Mage = 19.2, SD= 4.7) athletes from variety of sports voluntarily participated in this study. Perceived Socio-cultural Influences on Body Image and Body Change Questionnaire (McCabe, & Ricciardelli, 2001) was administered to all participants. In this study only the perceived pressure from media was evaluated. Athletes were grouped into two sport experience (less experienced: 5 & less years and more experienced: 6 & more years) and two sport type (team: handball, soccer, basketball, volleyball & individual: figure skating, weight lifting, swimming, wrestling, fencing, karate, track and fields) categories based on year of sport experience and types of sport that they were involved.

Multivariate Analysis of Variance for testing the gender differences revealed significant differences in perceived pressure from media on body image concerns of male and females athletes (Hotelling’s T2 = 0.08, F(3,299) = 7.79, p < .01). Follow-up univariate analysis demonstrated that female athletes perceived more pressure from media to lose weight than male athletes (F(1,302)= 5.83, p < .05) than female athletes. The sport experiences and sport type differences in the perceived influence of media on body image concerns was tested by Multivariate Analysis of Covariance by using gender as a covariate. MANCOVA results demonstrated significant multivariate main effect of sport types (Hotelling’s T2 = 0.09, F(3,297)=8.65, p < .01) and sport experience (Hotelling’s T2 = 0.03 F(3,295) =2.66, p < .05). The multivariate main effect of sport experience could be attributed to the pressure from media to lose weight (F(1,299)=7.61, p < .05). More experienced athletes perceived more pressure to lose weight as compared to less experienced athletes. Furthermore, follow-up univariate analysis indicated that team sport athletes reported more pressure from media to lose weight (F(1,302)=17.61, p < .01), gain weight (F(1,302)=15.54, p < .01) and improve muscle tone (F(1,302)=20.65, p < .01) than individual sport athletes.

As a conclusion, these findings suggest that the media are sending messages about the ideal body shape to Turkish athletes and particular media outlets give Turkish athletes the idea that they should be slimmer, eat less to lose weight, and eat less to be more muscular.

CONFIRMATORY FACTOR ANALYSIS OF THE MALAY VERSION OF THE SPORT ANXIETY SCALE - 2

Hashim, H.
Universiti Sains Malaysia, Malaysia

Significant progress in competitive anxiety research has yielded a better understanding for practitioners to deal with anxiety (Martens, Burton, & Vealey, 1990). A clear distinction has been made between trait and state anxiety. The former refers to the general tendency to
perceive certain situations as threatening, while the latter refers to feelings of apprehension and tension that are associated with arousal. It has been suggested that the intensity and magnitude of state anxiety is proportional to the perceived threatening situation. Thus, an individual, who is high in trait anxiety, is likely to experience greater state anxiety than an individual who is low in trait anxiety (Halvari & Gjesme, 1995; Spielberger, 1966). Sport competition can be a major source of stress among young sport athletes. Given the debilitating effect of competitive anxiety to children overall sport participation, knowledge of children competitive trait anxiety may be beneficial in both of performance and developmental perspectives. However, its assessment has proven to be problematic because of measurement difficulties (Smith, Smoll, Cumming, & Grossbard, 2006). Smith et al. (2006) recently developed the Sport Anxiety Scale 2 (SAS-2) to assess competitive trait anxiety in children. Given its utility in both research and applied settings, SAS-2 has been translated into Malaysian language. However, without appropriate psychometric assessment, the translated version may be problematic in terms of functional equivalence. Thus, the present study sought to examine the validity and reliability of the Malays version of the SAS-2. The questionnaire was administered to 73 elite youth sport athletes. Using Confirmatory Factor Analysis (CFA), the results revealed a satisfactory goodness of fit of the model (chi-square = 121.439, df = 87, p < .05; RMR = .04; GFI = .84; CFI = .91; RMSEA = .07). Significant Unstandardized Regression Weights (< .05) for all of the path loadings were obtained. Furthermore, all of the Standardized Regression Weights were above .50. The results also revealed an acceptable reliability for the subscales (Alpha = .78 for Somatic, .83 for Worry, and .75 for Concentration disruption subscales). Overall, the findings support the construct validity and reliability of the Malay version of SAS-2. However, further studies with larger sample are needed to confirm if the findings were sample specific or more general.

OP-SM03 Sports Medicine 3 - Elite Athletes

ENDOCRINOLOGICAL STUDY ON THE EFFECTS OF TESTOSTERONE GEL APPLICATION IN MALE ATHLETES

Ruhr-University Bochum, Germany

Introduction:

Testosterone gel is used for the treatment of testosterone deficiency in males. Testosterone is a hormone with strong anabolic effects and, therefore, belonging to the list of prohibited substances in sport. In the case of testosterone gel application results of preliminary studies indicate that the T/E ratio increases by a decrease of the epitestosterone concentration to stable, slightly elevated values with normal variations during the day. Under this misuse in sport, the steroid profiles appear like profiles of individuals with natural increased T/E ratios based on a decreased epitestosterone excretion. The misuse is, therefore, not detectable so far. One possibility to detect the misuse of testosterone gel might be an endocrine test on the integrity of the hypothalamo-pituitary-gonadal axis (HPGA).

Therefore, the aim of the study was to investigate the effects of testosterone gel applications in physically active young male subjects on the stimulatory pattern of LH, FSH and testosterone.

Methods:

The study was approved by the responsible ethical committee. All subjects gave their written informed consent. 9 healthy male subjects were included. Integality of the hypothalamo-pituitary-gonadal axis (HPGA) was tested by means of exogenous Gonadotropin-Releasing-Hormone (GnRH) injections (0.1 mg Relefact LRH) prior to, during every 7 days, and after a six week period of transdermal testosterone gel application (100 mg testosterone/d). Venous blood was collected prior to, 30, 75 and 120 min after GnRH injection.

Results:

Mean basal LH and FSH declined significantly during the application period. Values were (prior to and week 1 to week 6): LH (IU/l): 4.5, 2.6, 2.4, 2.4, 1.9, 1.8, 2.1; FSH (IU/l): 4.2, 2.5, 2.6, 2.5, 2.4, 2.2, 2.3. Maximal LH after GnRH increased in the first week and then declined, like FSH from the first week on, continuously during testosterone gel application. Values were: LH (IU/l): 37, 33, 24, 19, 16, 17, 13; FSH (IU/l): 7.2, 6.2, 5.4, 5.0, 4.3, 4.4, 3.5. Basal total testosterone as well as free testosterone increased from the first week of gel application and constantly remained elevated on nearly the double level. Values were: total testosterone (pg/ml): 19, 34, 40, 41, 43, 47, 41; free testosterone (pg/ml): 13, 24, 23, 26, 28, 40, 27. There was no significant effect of exogenous GnRH on either total or free testosterone.

Conclusion:

Daily transdermal testosterone gel application is capable to approximately double serum testosterone concentration in healthy young active male subjects from the first week of application, and to suppress pituitary LH and FSH secretion after the second week. This suppression of the endocrine axis might be detected by means of several exogenous GnRH injections over time.

The study was financially supported by the World Anti Doping Agency, Ontario, Canada.

THREE-PHASE BONE SCINTIGRAPHY FINDINGS AND EXERCISE EFFECTS IN CHRONIC EPICONDYLITIS

Pienimäki, T., Takalo, R., Karppinen, J.
Finnish Institute of Occupational Health, Finland

Introduction:

Bone scintigraphy is a tool to image injuries and recovery in the musculoskeletal system. In this study bone scintigraphies were performed in different stages of rehabilitation in patients with chronic epicondylitis and the uptake intensities were compared to rehabilitation results.

Methods:

Three-phase bone scans were performed after an intravenous injection of 550 MBq of 99mTc hydroxymethylene diphosphonate in 42 patients (74% women, mean age 41 years) with chronic epicondylitis. The images were evaluated using X-Rite 331 B W Transmission Densitometer. The scans were performed once for each patients either prior to exercise rehabilitation (n=19), during rehabilitation (n=12) and after an 8 weeks’ exercise rehabilitation intervention (n=11). From the images the maximal 99mTc-HDP uptake of each epicondylus and the mean value of adjacent humerus were calculated as epicondylus to humerus ratio and the same was done for the...
corresponding healthy epicondyle and for the affected arm's opposite epicondyle and differences between these two reference points and the affected epicondyle were calculated. Besides clinical examination, grip strength and pain thresholds (PPT) of the cubital region were measured and a pain and disability questionnaire with VAS and a whole body pain drawing were inquired before and after the rehabilitation intervention. The bone scintigraphy results were compared to rehabilitation results at each measurement point.

Results. In general, high 99mTc-HDP uptakes were associated with better functional status of the arm. Before rehabilitation, low uptakes were associated with higher improvements in pain at rest (p=0.005) and in manual test results (p=0.04) and high difference of uptake with the corresponding epicondyle with improved PPTs of epicondyles (p=0.04). During rehabilitation low uptakes were associated with improved PPTs (p=0.022) and low difference between affected and the same hand's opposite epicondyle with improved PPTs, grip strength and palpatory finding. After exercise rehabilitation intervention high uptakes were associated with significant improvement in pain at rest (p=0.048), improved PPTs of the epicondyle (p=0.032) and low uptakes with improved PPTs of the arcade of Frohse. Small differences in uptakes between the affected and corresponding healthy epicondyle were associated with improved pain drawing (p=0.01), and high differences with improved manual test results (p=0.008).

Conclusions. Increased 99mTc-HDP uptake in bone scintigraphy in chronic epicondylitis reflects healing response of the disorder, which can be classified according to the uptake intensity. It seems that uptakes will get lowered as a response for exercises. Evaluation of 99mTc-HDP uptakes can help to distinguish different types of epicondylitis from each others to plan suitable rehabilitation.

MARATHON RUNNING ENHANCES THE MIGRATORY ACTIVITY AND PROLIFERATION OF PC-3 TUMOUR CELLS

Tunca, E., Siliko, M., Hoffmann, A., Krüger, K., Mooren, F.
Sports Sciences, Justus-Liebig-University, Giessen, Germany

There is evidence from epidemiological studies that exercise can reduce the tumour incidence at least for some cancer types such as breast and colon cancer. Moreover, it has been shown that physical activity and exercise have beneficial effects on different physiological and psychological aspects of cancer patients. However, much less is known about the underlying mechanisms how exercise affects tumour progression. One important step of tumour progression is the development of tumour metastasis, which depends on migration and invasion of tumour cells into adjacent extracellular matrix, lymphatic systems or blood vessels.

The aim of this study was therefore to analyse the effect of exercise on the migratory behaviour and proliferation of tumour cells and to study the intracellular calcium homeostasis, which is an important second messenger.

Serum was taken from 10 male trained subjects before (pre) and 1 hour after (post) finishing a marathon run. The migratory behaviour of the androgen-independent prostate cancer cells PC-3 was analysed by performing a 3D-migration assay using collagen type I. Migration was recorded by time-lapse video-microscopy for 6 hours and was analysed by selecting 30 cells of each recording. The migration paths were digitized in 15 minute intervals by computer-assisted cell tracking. For the investigation of the proliferation rate, aliquots of the cells were cultured with either marathon serum, fetal bovine serum, or medium only until one group reached the confluent state. To analyse the possible underlying mechanisms intracellular calcium concentration ([Ca2+]i) was measured spectrophotometrically using the Ca2+ sensitive fluorescent dye Fura-2.

Treatment with post serum increased significantly the migratory activity and the mean migrated distance of PC-3 cells compared to treatment with pre serum. The velocity of the migrating cells remained unchanged. Proliferation of PC-3 cells was higher after incubation with post serum than with pre serum. In contrast, treatment of the PC-3 cells with pre serum lead to significantly higher [Ca2+]i levels than treatment with 1 hour post serum. This result could be confirmed also under calcium free conditions.

Our results suggest that long distance running enhances the migratory behaviour and proliferation of the prostate cancer cells PC-3. Marathon running seems to elevate serum factors which are able to increase both functions. In addition, it seems that these factors act predominantly through calcium-independent pathways. Further studies have to be done to get insights into the involved mechanisms and serum factors.

SORE THROATS IN ELITE ATHLETES: INFECTIONS OR INFLAMMATION?

Gleeson, M., Cox, A., Pyne, D., Callister, R., Ried, V., Clancy, R., Saunders, P., Fricker, P.
University of Newcastle (1) and Australian Institute of Sport (2), Australia

Background: Sore throats, oropharyngitis suspected to be upper respiratory infections (URTI) are a common health issue for elite athletes. They cause disruptions to training and can impact on optimal competitive performance (2). Despite extensive studies, a full understanding of the aetiology of sore throats in elite athletes is still uncertain.

Studies: Two prospective studies were undertaken to clinically assess elite athletes presenting to sports medicine clinics with URTI (3,4). An anti-viral agent and an anti-inflammatory agent (intervention studies) were assessed in prophylactic DBPC trials for efficacy to prevent the upper respiratory symptoms URS in elite runners (5,6).

Results:

Clinical 1 (3): In the first clinical study (n=41) physicians identified 22 athletes as having recurrent URTI (55%), however laboratory tests only identified evidence of infections or herpes virus reactivation in 27%. Other treatable medical conditions were identified in 50% of the athletes, including allergy (15%), asthma (16%), and airway dysfunction (5%).

Clinical 2 (4): In the second clinical study (n=70 physicians classified 89% as URTI), while pathology investigations only identified infections in 30%, with a further 27% of athletes with evidence suggestive of infections. There was no evidence of infection in 43% of athletes. Allergy was identified in 39% of the athletes.

Intervention 1 (5): An antiviral agent ValtrexTM reduced the viral load in elite runners (n=20) but did not reduce the incidence of URS.

Intervention 2 (6): The prophylactic use of a topical anti-inflammatory throat spray DifflamTM did not reduce the frequency of URS in elite runners (n=25) but did reduce the severity of the symptoms.

Conclusions. Symptoms of a sore throat in an elite athlete are not always associated with an infectious aetiology. Less than half the athletes associated with the two clinical studies had laboratory-based evidence of an infection. Other inflammatory causes of the URS should be considered, as treatable medical conditions were identified, with a high prevalence of allergy and asthma. The lack of a reduction in episodes of URS in response to an antiviral agent indicates that viral infections are not the major cause of the symptoms in runners. The reduced severity of symptoms in response to the topical anti-inflammatory throat spray supports an inflammatory cause for the symptoms that does not have an infectious aetiology. Mechanical damage to the airway epithelium is highly likely in these elite athletes undergoing intense training regimes.

ARE FORMER FEMALE ELITE ATHLETES MORE LIKELY TO HAVE URINARY INCONTINENCE LATER IN LIFE THAN NON-ATHLETES?

Ba, K., Sundgot-Borgen, J.
Norwegian School of Sport Sciences, Norway

Background
Symptoms of pelvic floor dysfunction, e.g. stress (SUI) and urge incontinence, are prevalent in female athletes (1). There is scant knowledge about the long-term effect of strenuous physical activity on prevalence of urinary incontinence. The aim of the present study was to investigate whether former female elite athletes are more prone to urinary incontinence later in life than non-athletes.

Methods
Female senior or junior athletes from 39 different sports participating at the national team level in 1988-1990 were the target group for this study. 331 former elite athletes (response rate 81%) and 640 controls replied to a postal questionnaire on physical activity level and general health status including validated questions on urinary incontinence. The study was approved by the Regional Ethics Committee. Chi-Square and Fisher Exact Test were used to compare differences between groups. P-value was set to ≤ 0.05. Logistic regression analysis was used and results reported as adjusted odds ratios (aOR) with 95% confidence intervals (95% CI).

Results
Mean age was 37.5 (SD 4.0) and 39.3 (SD 5.4), BMI 23.2 (SD 3.3) and 25.2 (SD 4.7), parity 2.2 (SD 0.8) and 2.3 (SD 1.1) and percentage of postmenopausal women 15 and 11.5 % in the elite athletes and controls respectively. 10.9 % and 2.7% of the former elite athletes reported SUI and urge incontinence, respectively while competing in sports. Presently, 36.5% and 36.9% reported SUI in the former athlete and control group. 9.1% and 9.4% reported urge incontinence. 77.8% of the athletes reporting SUI during their athletic career reported SUI at present. Significantly more former athletes reported urinary leakage during physical activity than controls (20.4% versus 15.3%, p= 0.048), but not during coughing and sneezing. In the former elite athlete group women having 2 (aOR 2.66, 95% CI: 1.32-5.35) or 3 (aOR 2.69, 95% CI: 1.23-5.90) children and having urge incontinence while competing in sports (aOR 8.57, 95% CI: 3.55-20.71) were more likely to report urinary incontinence now. In the control group women with higher BMI (aOR 1.07, 95% CI: 1.03-1.12), 2 children (aOR 1.77, 95% CI: 1.04-2.98) and 3 children (aOR 2.03, 95% CI:1.13-3.66) were more likely to report urinary incontinence. Age, menopause and being regularly physically active now were not associated with urinary incontinence in either group.

Conclusion
The prevalence of urinary incontinence is not higher in former athletes than in controls, except during physical activity. However, this study indicates that urinary incontinence early in life as reported during elite sport is a strong predictor of urinary incontinence later in life. Hence, the effect of prevention and treatment strategies such as strength training of the pelvic floor muscles should be evaluated in elite athletes.

OP-TT06 Training and Testing 6 - Failure

EXERCISE TRAINING EFFECTS ON VENTILATORY ANAEROBIC THRESHOLD IN PATIENTS WITH CHRONIC HEART FAILURE

Karatzanos, L., Anagnostakou, V., Kravari, M., Agapitou, V., Dimopoulos, Sf., Georgantas, A., Papazachou, O., Tsagalou, E., Malliaras, K., Nanas, S.
National & Kapodistrean University of Athens, Greece

Introduction: Anaerobic threshold is an index of prognosis and submaximal exercise capacity in patients with chronic heart failure (CHF). On the other hand, it could be considered a reference point for prescribing intensity at exercise training rehabilitation programs. This study was aimed at investigating the effects of exercise training on the ventilatory anaerobic threshold (AnT) in CHF patients.

Method: Thirty stable CHF patients, 23 male and 7 female (mean±SD age: 53.4±10.4 years, VO2peak: 15±5.1 ml/kg/min) participated in an exercise training program for 12 weeks, 3 times/week. Participants were randomly assigned to either aerobic (AER, n=14) or combined (COM, n=16) exercise training. Aerobic exercise was performed in interval type (30 sec exercise at approximately 110% maximum power output – 90 sec rest) on cycle ergometers. Strength training involved exercises for various muscle groups of the legs (quadriceps, hamstrings), the shoulder zone and the arms. Both regimes were of the same duration. All participants performed a symptom-limited maximum cardiopulmonary exercise test at the beginning and the end of the program. Increments were adjusted according to Wasserman's norms. Criteria of assessing AnT included the V-slope method, VE/VO2 - VE/VCO2 and PetO2 - PetCO2 plots, while the corresponding VO2 (VO2AnT) and power output (WAnT) were calculated by the gas analysis system software.

Results: The whole cohort improved (p<0.05) VO2AnT (from 9.9±2.8 to 10.9±2.7 ml/kg/min) and WAnT (from 58.1±22.1 to 69.2±23.2 watt). AnT, expressed in % of VO2peak predicted, was also improved (p<0.05, 33.6±8.2 to 37.0±7.4, p<0.05). No differences were found (p>0.05) in VO2AnT and WAnT, expressed in % max VO2AnT: from 65.7±8.0 to 64.5±10.2 %, WAnT: from 58.2±7.0 to 59.4±8.2 %). No between-group differences were observed (p>0.05), except for WAnT, in which COM (from 55.5±26.1 to 70.3±29.7 watt) tended (p=0.07) to improve more than AER (from 60.7±17.8 to 68.0±15.0 watt). The whole group also increased (p<0.05) VO2peak (from 15.1±5.1 to 17.2±5.2 ml/kg/min) and Wmax (from 98.1±36.3 to 115.6±36.7 watt).
Conclusion. An exercise training rehabilitation program, either aerobic or combined, enhanced $\text{AnT}$ in CHF patients. These improvements were found to relate to enhancement of maximal oxygen uptake and maximal power output rather than qualitative improvement of $\text{AnT}$ per se.

**INTERACTION-DOMINANT DYNAMICS OF FATIGUE IN ISOMETRIC EXERCISE UNTIL FAILURE**

Balgue, N., Hristovski, R., Vallejo, L.

**HAMSTRING/QUADRICEPS RATIO IN ATHLETES**

Muscle fatigue is defined as an exercise-induced reduction in maximal voluntary muscle force and it is said that has peripheral and central causes (Gandevia, 2001). The investigation of such causes and its individual components, as linearly loosely coupled and additively decomposable subsystems, centres most of the research in the classical approach to fatigue. Within this research paradigm the main aim is to find and locate the key or dominant factors of fatigue and failure for each task under investigation. In our opinion, the key question of explanation of fatigue and task failure phenomena is the following: Is the development of fatigue a component - dominant or interaction dominant self-organizing process? That is, is the internal dynamics of the components that bring about the task failure dominate over the interactions between them or vice versa? This is of a key importance because the two different kinds of processes would manifest different dynamics of the developing fatigue and task failure.

The objective of this research was to test the hypothesis of interaction-dominant dynamics in the fatigue development during a local isometric exercise until failure. Six subjects familiarised with the task performed during 5 alternative days an isometric arm curl exercise with 90° elbow flexion holding an Olympic bar weighting the 80% of their $1$-RM until failure. The subjects sat on an inclined forward bench with aim to isolate the prime movers in the elbow joint of both upper extremities. An electrogoniometer (Biometrics) and its software (Ebiom) were used to record the elbow angle in both extremities during the trials. The rate of perceived exertion was recorded during the exercise. It has been demonstrated that the developing fatigue is manifested by long-range correlations between the measured states of the investigated system. This fact points to an interaction dominant dynamics of the developing fatigue and task failure. The component processes have strong mutual vertical and horizontal interactions on each time scale of the fatigue development. This process leads the system through different highly correlated (i.e. history dependent) metastable configurations and forms the performance trajectory for each individual bout. The enhanced fluctuations immediately before the failure point are a result of these correlated processes and are another corroborated of the conjecture that task failure is an interaction - dominated self-organizing phenomenon.

**ASSOCIATION OF LEG VOLUME AND LEG MASS WITH ANAEROBIC PERFORMANCE, ISOKINETIC KNEE STRENGTH AND HAMSTRING/QUADRICEPS RATIO IN ATHLETES**

Kin-Islar, A., Ayyse, K., Ozkan, A., Aytar, A., Gulsen, M.

**Baskent University, Turkey**

The present study aimed to determine the relationship of leg volume and leg mass with anaerobic performance, isokinetic knee strength and hamstring/quadriceps (H/Q) ratio in athletes. Twenty male athletes from volleyball (n=6), basketball (n=6) and soccer (n=8) participated in this study voluntarily (Mage: 21.6±1.8 yrs; Mweight: 80.9±8.3 cm; Mweight: 75.3±6.1 kg). Leg volume of the athletes was determined by circumferential measurements and leg mass was determined by Hanavan method. Anaerobic performance was evaluated by Wingate anaerobic power test. Peak isokinetic concentric knee extension and flexion torques of both legs were tested at 60 and 300°/s and H/Q ratios were calculated for these movement velocities. Significant correlations were obtained between leg volume of the right leg and peak power (r=0.514; p=0.020), right knee flexion torque at 300°/s (r=0.620; p=0.004) and right H/Q ratio at 300°/s (r=-0.495; p=0.027). Results also indicated significant correlations between right leg mass and right knee extension torque at 60°/s (r=0.536; p=0.011), knee extension torque at 300°/s (r=0.463; p=0.040) and knee flexion torque at 300°/s (r=0.645; p=0.002). For the left leg volume significant correlation was obtained only between left knee flexion torque at 300°/s (r=0.509; p=0.022) and for the left leg mass significant correlations were found between peak power (r=0.575; p=0.008), average power (r=0.498; p=0.026) and left H/Q ratio at 300°/s (r=-0.473; p=0.035). As a conclusion the present results suggest that right and left leg volume and leg mass play different roles in anaerobic performance, isokinetic knee strength and H/Q ratio of male athletes.

**EFFECT OF CONCURRENT STRENGTH AND ENDURANCE TRAINING ON THE ENERGY COST OF RUNNING**

Bosquet, L., Berryman, N., Maurel, D.

**UNIVERSITY OF MONTREAL, Canada**

Purpose: The purpose of this study was to compare the effect of two strength training programs designed to increase maximal power on the energy cost of running in endurance athletes. Methods: Thirty moderately trained endurance athletes were separated into two groups matched for maximal oxygen consumption. They entered a training protocol that involved 2 high intensity interval training sessions, 1 moderate intensity continuous training session and 1 strength training session per week, for 8 weeks. All training sessions were identical between groups, except strength training sessions. Group A used concentric training with the resistance leading to maximal power as determined by a force velocity test in half-squat. Group B used plyometric training with the height leading to maximal power as determined by a drop jump test. The number of sets and repetition was the same for both groups. A maximal graded exercise test (treadmill), determined by a force velocity test (half-squat) and a performance test (3000 m on an indoor track) were performed before and after the training protocol. Results: Three subjects in group A and 4 subjects in group B withdrew from the study because of injury (n = 5) or lack of motivation to complete the protocol (n = 2). Concurrent strength and endurance training did not alter maximal oxygen consumption (pre-post mean ± standard deviation = 57.4 ± 6.7 vs 56.1 ± 6.7 ml.min⁻¹.kg⁻¹ in group A, and 57.5 ± 6.5 vs 57.3 ± 5.5 ml.min⁻¹.kg⁻¹ in group B, respectively, p > 0.05), nor aerobic endurance, as measured by the percentage of peak treadmill velocity sustained during the performance test (87.1 ± 4.7 vs 87.1 ± 2.8% in group A, and 87.6 ± 3.8 vs 86.8 ± 3.9% in group B, respectively, p>0.05). Both groups increased maximal power (1147 ± 180 vs 1324 ± 181 Watts in group A, and 1174 ± 139 vs 1214 ± 190 Watts in group B, respectively, p < 0.01). We found a significant interaction between time and group for the energy cost of running, the improvement of group B being higher than that of group A (0.207 ± 0.015 vs 0.199 ± 0.012 ml.kg⁻¹.m⁻¹ in group A, and 0.218 ± 0.016 vs 0.203 ± 0.013 ml.kg⁻¹.m⁻¹ in group B, respectively, p<0.05). The improvement of performance was similar between groups (755 ± 87 vs 724 ± 77 seconds in group A, and 748 ± 81 vs 712 ± 76 in group B).
B, respectively, p<0.001). Conclusion: Concurrent strength and endurance training improved maximal power and did not alter negatively the components of aerobic fitness, including maximal oxygen consumption and aerobic endurance. Plyometric training was more efficient than concentric training to improve the energy cost of running. Several hypotheses can now be tested to understand this difference, the main being an improvement of the capacity to use elastic energy.

THE USE OF AN ONLINE TRAINING DIARY TO DISTINGUISH BETWEEN FUNCTIONAL AND NON FUNCTIONAL OVERREACHING: A PILOT STUDY

Piacentini, M., Minganti, C., Olivi, M., Nederhof, E., Capranica, L., Meeusen, R.
Istituto Universitario di Scienze Motorie, Italy

Functional overreaching (FOR) is defined as short term performance decrement without severe psychological or negative symptoms. When the imbalance between training and recovery continues, non functional overreaching (NFOR) may occur. The distinction between NFOR and Overtraining syndrome (OTS) is very narrow, and occurs mostly on exclusion criteria (Meeusen et al. 2006). Although many markers have been proven to identify OTS, prevention remains the most important issue. Considering that it is difficult to standardize a method that can detect in advance some “early warning signals” of NFOR or OTS, the purpose of the present study was to evaluate the correlation between subjective and objective data of an online training diary before (PRE) and after (POST) 4 weeks of intensified training (IT) and 2 weeks of recovery (REC) and their relationship with performance and hormonal outcomes.

Methods
Four students (23±1.9 yrs) participated in the present study, trained for 6 weeks, with 2 weeks of IT and 2 weeks REC (Haslon et al 2002) and were tested PRE and POST by means of 2 exercise tests to exhaustion separated by 4 hours (Meeusen et al 2004) and with the finger precuing test (FPT). 4-weeks prior to the beginning of IT and during the whole training period, subjects filled in a daily online training diary (BLITS®?) and the POMS for objective and subjective evaluations of training. Hormonal and performance data were measured with a Friedman test while a Pearson correlation was performed between training diary parameters.

Results
No differences were observed in exercise performance between PRE and POST however, hormonal response was dampened after IT (ACTH: 269% and 135% increase PRE and 3,9% and 27,4% increase POST 1st and 2nd test respectively, PRL 113% and 115% increase PRE and 11% and 64% increase POST 1st and 2nd test respectively). The increase in negative mood was significantly correlated with physical (PWB) and mental well being (MWB) measured on a visual analogue scale. PWB and MWB were significantly correlated (r=0,877). Moreover, training attractiveness was significantly correlated with both PWB and MWB. Strain (load*monotony) increased by 132 and 157% while the Van Loon predicting value (Time*Intensity*attractiveness*soreness*MWB) increased by 322 and 614% in the 1st and 2nd week of IT respectively. The FPT shows that after IT, total reaction time was longer.

Discussion
The results demonstrate that prior to performance decrements due to incorrect training or excessive load, subjective data and training diary parameters are the most visible predictors of FOR, and strongly correlated with negative mood. Therefore, the use of the online training diary seems a valuable tool for training monitoring and prevention of OTS.

THE LEVEL OF METABOLIC ACIDOSIS EFFECTS THE LACTATE MINIMUM HEART RATE IN A HEART RATE BASED LACTATE MINIMUM TEST

Perret, C., Labruyère, R.
Swiss Olympic Medical Center, Nottwil, Switzerland and ETH Zurich, Switzerland

Background: The heart rate based lactate minimum test (LMT) was found to be a reliable tool to estimate maximal lactate steady state (MLSS) with one single exercise test (1, 2). The LMT consists of two parts: i) an incremental test to volitional exhaustion leading to extensive lactic acidosis and ii) a heart rate based incremental test to determine lactate minimum. However, it still remains unclear, whether the first part of the LMT needs to be performed until exhaustion. If not, the practical application of the LMT to provide accurate training prescriptions might be widened to fields, where maximal performance is not always of interest or even risky (e.g. cardiopulmonary rehabilitation). Thus, the aim of the present study was to investigate, whether or not the level of the metabolic acidosis in the first part of the LMT influences parameters measured at lactate minimum.

Methods: 15 well-trained men (age 31±6 years, height: 179±6 cm, weight: 75.6±7.6 kg and VO2peak: 51.0±9.5 ml/min/kg) each completed two LMTs. The first part of the LMT was composed either of an incremental test to exhaustion (maximal test) or an incremental test abandoned three stages earlier than the maximal test (submaximal test). The second part of the LMT was the same for both tests. Average values of heart rate, blood lactate concentration, oxygen uptake, minute ventilation, respiratory exchange ratio, breathing frequency, power and rating of perceived exertion were compared at the end of the incremental tests as well as at lactate minimum.

Results: At cessation of the first part of the maximal test compared to the submaximal test average maximal blood lactate concentration was significantly higher (9.7±2.7 vs. 6.0±2.0 mmol/l, P<0.001). The same finding was also true for all other parameters measured. At lactate minimum mean heart rate was significantly higher after the maximal compared to the submaximal test (160±12 vs. 144±13 bpm, P<0.001). Further, all other variables (except for respiratory exchange ratio) showed significantly higher values at lactate minimum in the maximal compared to the submaximal test.

Conclusion: Based on the findings of our study, we conclude that the first part of our heart rate based LMT needs to be performed to volitional exhaustion in order to reliably predict MLSS.

Any active or stretched passive sarcomere within a muscle fiber will shorten to its active or passive slack length respectively, unless opposed by an equal opposite force. Therefore at equilibrium, sarcomere length is determined by the loads working on it. Usually, only loads exerted by myotendinous structures are considered. However, in addition to those loads, evidence is accumulating that also loads exerted via epimysial myofascial connections. This name indicates that the load is imposed via the epimysium (i.e. the muscle fascia). Such load can originate from non-muscular structures (bone, periost, compartmental fasciae, neurovascular tract, intermuscular septa) or muscles. In the latter case, it seems likely that extramuscular structures usually play an important role, even though some direct transmission between the connective tissue strata of adjacent muscles is also reported (Maas et al., 2006). As a consequence, the length of sarcomeres exposed to such myofascial loads will differ from those exposed exclusively to myotendinous loads. Therefore serial distribution of lengths of sarcomeres within a muscle fiber is likely. The locations of epimysial myofascial loading on the muscle fiber determine such distributions.

If all fibers of a muscle would be exposed to similar myofascial loads little or no distribution of fiber mean sarcomere length would occur (Yucesoy et al., 2003), as seen at certain conditions (see Fig. below). However, finite element modeling usually indicates parallel distributions of sarcomere lengths. The net epimysial myofascial load may have a proximal or distal orientation. The corresponding force related to such myofascial force transmission will be integrated into the opposite side origin or insertion. Therefore, force exerted at both sides should not be expected to be equal. In the example shown force would be bigger at the distal tendon. Recently it has been shown that such additional myofascial force may well originate from antagonistic muscles (e.g. Huijing, 2007; Huijing and Baan, 2008). Experimental evidence and conditions for such force transmission will be discussed.

**THE ROLE OF TENDON MECHANICAL PROPERTIES IN OPTIMISING MUSCLE OUTPUT IN SIMPLE AND COMPLEX LOCOMOTION ACTIVITIES**

Baltzopoulos, V.

Manchester Metropolitan University, United Kingdom

Muscle-tendon interaction in static and dynamic conditions has important implications for muscle function. One of the important questions, for example, is whether Achilles tendon compliance is optimised for maximum muscle efficiency during locomotion (e.g. Lichtward & Wilson, J Biomech, 40, 2007). The mechanical response of tendons is more complex than a linear spring and due mainly to the wavy pattern of the collagen fibres and the mix of collagen and elastin present, these tissues behave in a non-linear elastic manner. Furthermore, the high liquid content means that there are substantial viscoelastic effects in evidence. Stress at a given time depends not only on the elongation but also on the rate of elongation and other history effects.

In previous experiments of muscle-tendon interaction during locomotion it was shown, for example, that force was developed isometrically and this was interpreted as an energetically efficient mechanism. Increases in incline increased muscle fascicle length at which force was developed and it was suggested that the Achilles tendon allowed the muscle fascicles to act at speeds more favourable for power production. These findings also suggested that the function of the muscle fascicles at different slopes is relatively unchanged despite changes in the external work demands (Lichtward & Wilson, J Exp Biol, 209, 2006).

In human drop jump exercises the gastrocnemius medialis (GM) fascicles shortened throughout the ground contact (Ishikawa et al., J Appl Physiol, 99, 2005). In human walking experiments the GM fascicles contract isometrically (Fukunaga et al., Proc R Soc Lond, B268, 2001), or even lengthen (Ishikawa et al., J Appl Physiol, 99, 2005) during the single support phase when muscle tendon unit (MTU) and tendon are stretching. These findings show different/contradicting fascicle behaviour as fascicles did not follow the length change pattern of the MTU and perhaps movement specific fascicle behaviour (e.g. Ishikawa et al., Gait and Posture, 25, 2007).

In a series of experiments we examined gastrocnemius muscle fascicle behaviour during stair negotiation in humans (Spanjaard et al., J Appl Physiol, 102, 2007) and the influence of gait velocity (Spanjaard et al., J Electromyg Kinesiol, 2007) and step-height and body mass (Spanjaard et al., J Biomech, 2008). The main conclusions from dynamic stair negotiation activities are that the GM muscle was mainly active during the touch-down phase of stair descent where the MTU was lengthened; however, the GM muscle fascicles shortened by 7 mm. These findings show that the behaviour and function of GM muscle fascicles in stair negotiation is different from that expected on the basis of length changes of the MTU as derived from joint kinematics. This behaviour of muscle fascicles is not shown when walking down an incline by humans or other species and this difference is probably due to the toe landing in stair descent as opposed to heel landing during incline...
IN VIVO APONEUROSIS MECHANICS

Herzog, W.
The University of Calgary, Canada

Introduction: Since the seminal work by AV Hill (1), muscle has been considered as a contractile element (CE), and a passive nearly elastic element arranged in series (SE) with the contractile element. However, neither Hill nor contemporaries identified the structures that were thought to be arranged in series with the CE. With increasing possibilities for theoretical representation of muscles, the series elastic element was rediscovered and needed identification and characterization. Obviously, tendons are in series with muscles. However, other passive structures, specifically the functional arrangement of aponeuroses is not nearly as obvious. Nevertheless, aponeuroses have been considered by most to be part of the in series elasticity of muscle.

By definition, series elastic elements transmit the same force (or force in constant proportion), and elongate in proportion to that force. Several years ago, while measuring aponeuroses strains in the cat medial gastrocnemius (MG), we observed that elongations of the aponeurosis were not in proportion to muscle force and certain parts of the aponeurosis were shortening with increasing force. The purpose of this work was to critically study the properties of aponeuroses experimentally and theoretically.

Methods: Measurements of aponeuroses lengths were performed in isolated aponeuroses, in situ aponeuroses and in vivo aponeuroses of cat MG using sonomicrometry. Simultaneous force measurements in cat MG were made using buckle type tendon transducer (2). Human tibialis anterior aponeuroses properties were also measured using ultrasound imaging for a variety of conditions. Theoretical analyses of aponeuroses force transmission and elongation were performed using models of uni-pennate muscle configurations (3).

Results: Aponeurosis segments in cat MG were found to shorten for in situ isometric contractions, and during normal locomotion. Also, theoretical modeling of aponeuroses function in uni-pennate muscle revealed that forces along aponeuroses were not constant and aponeuroses could shorten with increasing force.

Discussion: It has been shown previously that aponeuroses might shorten upon force production (4) and that aponeuroses strains in active muscle can be smaller than in passive muscle for the same force (5). These observations are not compatible with aponeuroses being arranged mechanically in series with the contractile element. Our observations on cat MG support these findings and add the result that these properties are preserved for in vivo contraction and everyday locomotor activities.

Conclusion: For the muscles tested here, aponeuroses are not arranged mechanically in series with the contractile elements. Should this result prove generally correct, biomechanical models of muscle would need to account for it.

IS-PM09 Mechanisms leading to the metabolic syndrome

THE ROLE OF SLEEP AND SLEEP DISORDERED BREATHING IN THE METABOLIC SYNDROME

Taheri, S.
University of Birmingham and Birmingham Heartlands Hospital, United Kingdom

The role of sleep duration and sleep disorders in the regulation of metabolism is increasingly recognised. Data from large population studies show that both long and short sleep duration are associated with obesity, the metabolic syndrome, diabetes, cardiovascular disease and mortality. These studies have been carried out across all age groups, and in several countries and ethnic groups. Human sleep laboratory studies have shown that both short sleep duration and sleep disruption are associated with metabolic derangements that are associated with the metabolic syndrome and diabetes. Additionally, sleep disordered breathing, which results in sleep disruption, hypoxia, and daytime sleepiness is associated with hypertension and glucose intolerance. Some studies suggest reversal of metabolic abnormalities with the treatment of sleep disordered breathing with continuous positive airway pressure (CPAP). As a result, it has been suggested that metabolic syndrome (also called syndrome X) should be called syndrome Z because of its potential association with sleep and sleep disordered breathing. The evidence for the association between sleep duration and sleep disordered breathing and metabolism will be critically discussed including potential mechanisms that could contribute to associated metabolic abnormalities. These mechanisms include sleep disruption, intermittent hypoxia, short sleep duration and daytime sleepiness (and concomitant reduction in physical activity) could be mediated through changes in metabolic hormone levels and autonomic nervous system activity.

ABNORMALITIES IN MITOCHONDRIAL FUNCTION: CAUSE OR CONSEQUENCE

Dela, F.
University of Copenhagen, Denmark

Mitochondrial function may be compromised in insulin resistance and type 2 diabetes. Studies in insulin resistant humans have indicated that the oxidative phosphorylation capacity is diminished in skeletal muscle in these individuals. However, these findings have been challenged by high resolution respirometry studies in which a 10-20% decrease in mitochondrial function is fully accounted for by a reduction in mitochondrial content, as measured by citrate synthase activity and mitochondrial DNA content.

A diminished mitochondrial function in insulin resistant skeletal muscle might partly explain both the common finding of increased intra-myocellular lipids and the hyperglycemia present in type 2 diabetes. However, the reverse situation may also be a possibility, i.e. that the intra cellular lipids are the cause of decreased mitochondrial function. As far hyperglycemia, studies in endothelial cells have shown that in these cells a decreased mitochondrial function may be a consequence of glycaemia induced increased production of reactive oxygen species, with subsequent impairment of mitochondrial function.

The presentation will cover this scenario, and further add to the knowledge of human mitochondrial physiology by reporting new data on intervention studies in healthy and insulin resistant humans.
ROLE OF INFLAMMATION, PROTEIN KINASE C (PKC) AND NADPH OXIDASE IN THE METABOLIC SYNDROME

Wagenmakers, A.
University of Birmingham, United Kingdom

Insulin resistance in the metabolic syndrome occurs both at the level of skeletal muscle fibres and at the level of the endothelium of the microvasculature in skeletal muscle. A high release of fatty acids from the adipose tissue stores and high plasma triglyceride levels lead to high concentrations of fatty acid metabolites both in the muscle and in the vascular endothelium. This then activates PKC isomers that lead to serine phosphorylation of IRS-1. The latter has been proposed to prevent activation of IRS-1 by insulin induced tyrosine phosphorylation and downstream activation of the insulin-signaling cascade. This will lead to reduced GLUT-4 translocation and glucose uptake in the skeletal muscle fibres, and has been suggested to prevent activation of endothelial NO synthase (eNOS) in the terminal arterioles of the muscle microvascular bed. The latter has been proposed to lead to an impairment of the meal-induced increase in muscle capillary recruitment in obese subjects that is necessary to channel more glucose and insulin to the muscle fibres. The impairment in both of these mechanisms has been suggested to contribute to the reduction in glucose control in obese subjects with and without the metabolic syndrome. Both exposure to high fatty acids and inflammatory cytokines also leads to activation of NADPH oxidase in the vascular endothelium. NADPH oxidase produces oxygen superoxide anions (a damaging free radical), which will further reduce NO production by the (microvascular) endothelium via a reaction with NO under the formation of peroxynitrite. The further decrease in NO production will reduce the dilation of arteries and arterioles in response to meal-induced increases in insulin and exercise-induced increases in blood flow (shear-stress mediated). A low NO production has also been shown to prevent angiogenesis (leading to loss of muscle capillarities = rarefaction) and to lead to atherosclerosis in the metabolic syndrome. TNF-alpha and related members of the TNF-superfamily via activation of nuclear factor-kappaB have also been shown to induce the expression of cellular adhesion molecules (CAM) by the endothelial cells. This will lead to leucocyte adhesion and a local vascular inflammation that leads to further activation of NADPH oxidase, further reductions in NO production and that will enhance the rate of atherosclerosis. Inflammation of the microvasculature in the muscle also is causing insulin resistance in skeletal muscle via mechanisms that are not completely understood. All these pathogenic mechanisms are reversible by lifestyle interventions involving calorie restriction and regular exercise.

A PERCEPTION-ACTION APPROACH TO VISUAL SEARCH AND MOVEMENT BEHAVIOUR IN FOOTBALL

Savelsbergh, G.
Institute MOVE, Faculty of Human Movement Sciences, VU University, Amsterdam, The Netherlands

With its emphasis on the nature of information for action, Gibson's (1979) ecological approach to perception stresses the circularity between perception and action. Gibson argues that information for perception and action is provided by the change or persistence of optical information in the environment. It is in this sense that perception and action are tightly coupled. In the presentation the role visual information will be illustrated and discussed by examples from the stopping of a penalty kick and the movement behaviour of football player in a four-to-four position game. The first part of the presentation will deal with the use of visual information by goalkeepers in stopping a penalty kick. The aim of the experiment was to improve the estimation of the direction of the ball during penalty kicks by changing the visual search behaviour. Inexperienced goalkeepers divided into three groups moved a joystick in response to penalty kick situations presented on a large screen in a pre-test, training and post-test. The perceptual learning group practised with film clips that were edited with a highlight over the relevant information in the sequence of the run-up of the shooter. The self-learning group practised with the same film clips without any highlights. The third group served as control. The findings in the post-test showed that the visual search behaviour of the directed training group changed significantly through direction of attention, changed its time of initiation of the joystick which coincidence with the most important visual information and stopped significantly more penalties than the other two groups. It is concluded that perceptual learning can improve the visual search and movement behaviour of the goalkeepers.

In the second part of the presentation, a study is reported that examined differences in locomotor and visual search behaviour among a group of skilled 11-12 year old football players. The participants watched film clips of a 4-to-4-position game, presented on a large screen. The task for participants was to take part in the game by choosing the best position for the reception of the ball passed by one of the players in the clip. Participants' locomotor and visual search behaviours were collected continuously throughout the presentation of the clip. A within-group comparison was made based upon the participants' interception score. The findings show that the high-score group, i.e. more at the correct position, looked more to the ball, while the players in the low-score group concentrated on the receiver and on the hips/upper body region of the passing player. In addition, the distance covered between the two groups differed significantly. It is concluded that the within-group comparison revealed differences in visual search and behaviour that can be used as indicators for talent.

The presentation will be ended with suggestions and implications for sport science research from a perception-action perspective.

UNDERSTANDING PERCEPTUAL MECHANISMS AND DECISION MAKING IN SOCCER

Craig, C.
Queen's University Belfast, Ireland

Deciding when and how to move is very important when trying to stop a ball from entering the goal in soccer. Goal-keepers must attend to pertinent visual information (player and ball) that will allow them to judge where the ball is going to get their body in the right place at the right time. The aim of this presentation is to explore how this type of perceptual information influences decisions about action.

In soccer more and more teams are exploiting the free-kick scenario as an opportunity for scoring goals (Grant et al, 1999). This appears to be related to the free-kick specialists' ability to bend the ball around the defensive wall. Why do players try to put spin on the ball to...
make it curve? Does this deviation in the ball’s trajectory make it more difficult for the goalkeeper to anticipate where the ball is going and subsequently control their actions to actually get there? In other words, does spin give the attacker a competitive advantage? Experimental work will be presented that shows how a deviation in the ball’s trajectory affects players’ decisions about when and how to act. By immersing players in a virtual soccer stadium and allowing them to interact with realistic curved free kicks we were able to see the extent to which lateral deviations in a ball’s trajectory impact upon the decision making process (Craig et al., 2006). An in-depth behavioural analysis allowed us to examine the relationship between perceptual information picked up through the senses and the control of action. The implications of these findings will be discussed in light of how the dynamics of the environment (e.g., movement of other players and/or the ball) provide prospective information for the player and directly influence decisions players make about their future course of action.

VISUAL EXPLORATION IN PREMIER LEAGUE FOOTBALLERS

Jordet, G.
Norwegian School of Sport Sciences, Norway

The extent to which skilled athletes use more appropriate and effective visual search strategies than less skilled athletes has been under some debate (e.g., Williams & Ward, 2007). Unfortunately, few studies have been conducted with expert athletes in real world competitive contexts. The purpose of this study was to learn more about the ways expert athletes use visual exploratory activity (Gibson, 1979) to prospectively control their actions under dynamic and complex performance conditions. In particular, we wanted to find out whether visual exploration frequency is related to performance with the ball in professional soccer games. Real-world close-up video images were obtained from Sky Sport’s split screen PlayerCam broadcasts in the 2003-2004 season, generating 442 game situations with 54 midfield players from the English Premier League. In addition, split screen video footage was obtained with 27 Dutch amateur level players (114 situations). Close-up video observation analyses made it possible to examine how players moved their bodies and heads, with their faces directed to players away from the ball (exploratory activity), prior to receiving the ball. Performance was indirectly assessed from level (Premier League or amateur) and player status (international awards), and directly assessed from the videos (e.g., pass completion percentage). The data was analyzed with ANOVAs and logistic regression analyses.

The results indicated a positive relationship between visual exploration frequency and performance. The Premier League players explored more than the amateur players (p < .01) and within the Premier League group, the players with international awards explored more than those without awards (p < .01). In addition, there was a positive relationship between exploration frequency and pass completion rate (p < .05). Specifically, in situations where players had the lowest exploration frequency (0-0.30 searches/s), they completed 57% of their passes, with medium frequency (0.31-0.50) this increased to 70% and with high frequency (0.50-1.25) to 75%.

In conclusion, the positive relationship between exploration frequency and performance is consistent with predictions from the ecological approach to perception (Gibson, 1979). It is possible that by exploring more extensively, actively moving one’s body and head, players detect more relevant and accurate information that can be used to control their prospective actions with the ball. Developing more ecologically valid research protocols for studying perceptual expertise in team ball sports are encouraged.

OP-BI02 Biochemistry 2

EFFECT OF ALLOPURINOL AND EXERCISE ON OXIDATIVE STRESS MARKERS IN GASTROCNEMIUS MUSCLE IN RATS

Kouretas, D., Yeskoukis, A., Kokinos, D., Kyparos, A., Nikolaidis, M.
University of Thessaly, Greece

Allopurinol is an inhibitor of xanthine oxidase. Xanthine oxidase is a major contributor of free radicals during exercise. Previous studies from other laboratories have shown that free radicals are vital for physiological adaptations in exercise. The purpose of this study was to examine the effects of allopurinol, exercise, and their combination on oxidative stress markers in gastrocnemius muscle in rats. Eighty adult male Wistar rats (8 weeks old, weighing 220±10 g; mean±SEM), were randomly and equally divided into eight groups as follows: a) DMSO-treated rats killed at 1.5 h after administration, b) DMSO-treated rats exercised at 1.5 h after administration and killed immediately after exercise, c) DMSO-treated rats exercised at 1.5 h after administration and killed 5 h after exercise, d) exercised allopurinol-treated rats immediately after exercise, e) exercised allopurinol-treated rats killed 5 h after exercise, f) allopurinol-treated rats killed at 1.5 h after administration, g) allopurinol-treated rats killed at 2.5 h after administration, and h) allopurinol-treated rats killed at 7.5 h after administration. Allopurinol was dissolved in dimethyl sulfoxide (DMSO) and administered intraperitoneally in a single dose of 50 mg/kg body weight at 1.5 h before the acute exercise protocol, as allopurinol peak plasma levels occur about 1.5 h after its administration. Exercise duration to exhaustion of DMSO-treated rats lasted approximately 1 h. Allowing 7 days of acclimatization in the animal facility, animals were then familiarized to swimming for a period of five days before the actual swimming protocol was implemented. Rats of the exercising groups individually swam until exhaustion in deep water tanks at a water temperature of 33/36 °C. Gastrocnemius muscle samples were collected before, immediately after and 5 h after exercise and in the respective time points after allopurinol administration. Tissue samples were homogenized using mortar and pestle followed by brief sonication treatment. Reduced (GSH) and oxidized (GSSG) glutathione, catalase activity, total antioxidant capacity (TAC), and thiobarbituric acid-reactive substances (TBARS) were determined. Allopurinol was found to increase GSH concentration, the GSH/GSSG ratio, catalase activity and TBARS concentration, whereas it decreased TAC. Similarly exercise increased GSH concentration, the GSH/GSSG ratio, catalase activity and TBARS concentration, whereas it decreased GSSG concentration. Allopurinol and exercise combined were found to increase GSH, the GSH/GSSG ratio and TBARS concentration. Allopurinol...
inhibits uric acid production to some extent via xanthine oxidase inhibition. This may be a possible explanation of the increased oxidative stress observed in gastrocnemius after allopurinol administration. The mechanism is discussed.

INVESTIGATION OF THE SP1-BINDING SITE POLYMORPHISM WITHIN THE COL1A1 GENE IN SUBJECTS WITH ACHILLES TENDON INJURIES AND CONTROLS

Posthumus, M., September, A., Schwellnus, M., Collins, M.
University of Cape Town, South Africa

Sequence variants within the type V collagen (COL5A1) and Tenasin C (TNC) genes have to date been shown to be associated with chronic Achilles tendinopathies and/or spontaneous Achilles tendon ruptures. Type V collagen and tenasin C are quantitatively minor components of tendon, while type I collagen is the major structural component. The expression of COL1A1 has been shown to increase in the painful Achilles tendon. The functional Sp1-binding site polymorphism SNP rs1800012 (IVS1+1023G>T) within the COL1A1 gene, which encodes for the α1 chain of type I collagen, has been shown to be associated with several connective tissue disorders. The aim of this study was to determine whether the Sp1-binding site polymorphism within the COL1A1 gene is associated with chronic Achilles tendinopathies and/or spontaneous Achilles tendon ruptures. Achilles tendinopathy (n=85), Achilles rupture (n=41) and asymptomatic control (n=125) subjects were genotyped for the COL1A1 Sp1-binding site polymorphism. There were no observed statistical differences in the genotype (P=0.602) or allele (P=0.694) distributions between the groups. In conclusion, this study has shown that there is no association between the Sp1-binding site polymorphism within the first intron of COL1A1 and Achilles tendinopathy or Achilles tendon rupture within the population studied.

TREADMILL EXERCISE ENHANCED LIVER NOT SKELETAL MUSCLE GLYCOGEN CONTENTS IN MALE RATS AT REST

Farshidi, Z., Ghanbari-Niaki, A., Barmaki, S., Ziaee, N., Fallah, S.
Tarbiat Modares University, Mazandaran University, Tehran, Babolveter-Mazandaran, Iran

Introduction: glycogen as a polysaccharide is stored in the liver and muscle at high levels and with low levels in heart, brain, erythrocyte, and lymphocyte. Glycogen also has been recognized as an important source of energy provision, particularly during prolonged exercise training. The effect of endurance training on tissues glycogen content is well documented. On the other hand, it has been suggested that endurance-trained rats have higher glycogen contents than sedentary match groups. Most of previous studies have focused on the temporary effect of high intensity exercise on muscle glycogen content, but they did not much focused on the effect of exercise training program at different intensities on resting muscle and liver glycogen simultaneously. The purpose of this study was to investigate the effect of treadmill exercise at different intensities on liver and skeletal muscle glycogen contents in male rats at rest. Methods: forty male Wistar rats (4-6 weeks, 250-260g) were used and divided into four groups: control, low (18m/min), moderate (26m/min) and high (34m/min) intensities. Training groups were undertaken of a motor-driven treadmill running at each mentioned intensities 60min/day, 5 days/week, for 12 weeks. Animals were sacrificed 36 hr after the last session of exercise training. All rats were overnight fast. A portion of liver and skeletal muscle (gastrocnemius) were removed, cleaned and immediately frozen by liquid nitrogen. Tissues glycogen was obtained by a commercial kit. Data were analyzed by one way ANOVA method and all P values <0.05 were considered significant.

Results: a higher level glycogen has been observed in trained rat liver not muscle when compared with control group. A higher and significant (P<0.01) resting liver glycogen concentration was only found in moderate intensity group. A lower and significant muscle glycogen concentration was observed in high and moderate intensities groups (P<0.01, P<0.024, respectively) when compared with control group. Discussion: a high liver glycogen in moderate intensity group and low level muscle glycogen in moderate and high intensity groups were found. A lower resting muscle glycogen content after a high intensity exercise might be attributed to a higher negative energy balance, glycogen content of muscle, possible exercise-induced muscle damage, and an incomplete recovery time following exercise plus short period of fasting. Conclusion: it seems that treadmill exercise at moderate intensity resulted in liver not muscle glycogen supercompensation in our experimental condition. A tissue glycogen content might be considered as a factor for glycogen restoration status and liver glycogen supercompensation has no direct impact on muscle glycogen restoration. Data indicate that there is no tissue preference and order for glycogen restoration during recovery period.

OXIDATIVE STRESS RESPONSE IN YOUNG JUDOISTS DURING FOUR WEEKS PREPARATION PERIOD TRAINING PROGRAM

Radovanovic, D., Bratic, M., Nurkic, M.
Faculty of Sport and Physical Education University of Nis, Serbia and Montenegro

BACKGROUND: Exercise can produce an imbalance between reactive oxygen species and antioxidant defense system, which is referred to as oxidative stress. Two major classes of endogenous protective mechanisms (enzymatic and non enzymatic antioxidants) work together to reduce the harmful effects of oxidants in the cell.

AIM: This investigation aimed to evaluate response of selected markers of oxidative stress in young judoists during four weeks preparatory period.

METHODS: Ten male judoists (mean±SD: age 20.1±1.3 years, body height 1.74±0.05 m, body weight 70.6±8.1 kg, body fat 7.3±2.9%) participated in the investigation. Blood samples, collected at rest before and after four weeks, were analyzed for the determination of selected markers of oxidative stress (malondialdehyde MDA, catalase CAT, carbonil and sulphhydryl group assay for determination of modified proteins and total antioxidant status TAS). The results were statistically evaluated by the Wilcoxon Signed Ranks Test.

RESULTS: There were no significant changes in erythrocyte MDA (median Me 13.84 µmol L-1 pre vs. 15.62 µmol L-1 post, p>0.05), plasma CAT (Me 7.21 IU L-1 pre vs. 9.44 IU L-1 past, p>0.05), catalase group (Me 0.71 µmol L-1 of proteins pre vs. 0.82 µmol g-1 of proteins post, p>0.05), sulphhydryl group (Me 191.06 µmol L-1 pre vs. 205.73 µmol L-1 post, p>0.05) and TAS (Me 49.91% pre vs. 52.67% post, p>0.05).

CONCLUSIONS: It can be concluded that this pattern of preparation period training program did not have any effects on oxidative stress levels in well-trained young judoists, and the body's natural antioxidant defenses respond adequately to increases in four weeks training program.

Key words: oxidative stress, judo, antioxidant defense, exercise.
Heat shock proteins (HSPs) act as molecular chaperones by refolding unfolded proteins. They control protein synthesis and trafficking, as well as regulating cellular adaptation and survival. Physical exercise provides a physiological stimulus for increased HSPs expression and up-regulate endogenous defences.

In the present study we investigated the effect of exercise and oxidant antioxidant intervention on the mRNA and protein expression of selected HSP and free radical concentration in the myocardium of rats. Methods: Thirty six, male Wistar rats were randomly assigned to one of six groups: non-exercised control injected with saline (NEC), non-exercised injected with oxidant H2O2 (NEH), non-exercise injected with antioxidant, N-tert-butyl-a-phenylnitrone (PBN) (INEP) and their respective exercised groups: exercise control injected with saline (EC), exercised injected with oxidant (EH) and exercised injected with antioxidant (EP). The experimental period lasted 10 weeks of inactivity or treadmill running. All animals were injected two weeks prior to sacrifice, every other day one hour before exercise. Results: Results revealed significant increase in HSP70 in all groups underwent exercise and significant increase in HSP25 and HSP90 only in EC group. No significant changes were found in HSP60 protein level. In addition, no differences were observed in any of the level of HSP mRNA among groups. The electron spin resonance (ESR) data for free radical concentration demonstrated significant decrease in free radicals in EC and NEP groups. Conclusions: HSP 70 induction seems to be sensitive to exercise training but not to oxidant or antioxidant interventions. On the other hand, HSP25 and HSP90 were induced by exercise alone while oxidant-antioxidant intervention attenuated their increase, emphasizing the redox regulation of cellular adaptations can be hampered by exogenous manipulations of oxidative stress. HSP60 showed no sensitivity to exercise or to oxidant-antioxidant stimuli. HSP mRNA level seems to be independent of protein level and it might be regulated by post-transcriptional modifications. Finally, exercise alone and antioxidant in sedentary animals have the capability of decreasing free radical concentration.

CONTRACTILE AND STRUCTURAL ALTERATIONS IN EDL MUSCLE FROM OB/OB MOUSE

Kemp, J., Blazev, R., Stephenson, D., Stephenson, G.
Victoria University, Australia

Animal models of obesity exhibit significantly higher body mass and lower skeletal muscle mass. This raises questions as to the contractile (and structural) status of skeletal muscle in the obese state, particularly in light of exercise being promoted as a therapeutic strategy. Here we combined whole muscle and single fibre methods to compare contractile properties (twitch and tetanic force, force-frequency relationship, fatigue resistance), myosin heavy chain isoform (MHCi) and fibre type composition and lactate dehydrogenase isoenzyme (LDHi) profile of the extensor digitorum longus (EDL) muscle from adult (18-22 wk) male C57 black (B6 V-Leip ob I/B) mice and its wildtype (lean) counterpart. For contractile measurements, the muscles were maximally stimulated at optimal length in carbogen (95% O2, 5% CO2)-bubbled Krebs solution with 10mM glucose and 10mM tubocurarine at 25±0.5 degrees Celsius. MHCi composition in both whole muscle homogenates and single muscle fibres and LDHi profile were determined electrophoretically. Mean body mass of obese and lean mice was 32.2±1.6 g (n=8) and 28.5±0.7 g (n=8), respectively. Mean muscle mass of EDL from obese mice (9.9±0.4 mg) was 27% smaller than from lean mice (13.5±0.7 mg). In comparison to EDL muscle from lean mice, EDL muscles from obese mice exhibited: (i) similar twitch and maximum tetanic forces per cross sectional area, (ii) shorter rate of force development of tetanus, (iii) longer half-relaxation time of twitch and tetanus, (iv) greater relative tension at suboptimal frequencies, (v) increased resistance to fatigue, and (vi) greater recovery of peak force post-fatigue. The predominant fibre type (~82%) in randomly dissected fibre populations from EDL muscles of both obese and lean mice was type IIb, however, the fibre population from obese mice compared with that from the lean controls, respectively.
contained a greater proportion of hybrid fibres (17.9% vs 4.5%), the majority co-expressing MHCIIdb and MHCIIdb (IIdb fibre). Consistent
with this result, EDL muscles from obese mice displayed a MHC IIIdb isoform ratio of 5.46 compared to that of 12.31 in muscles from
lean mice. The LDH profile of EDL muscles from obese mice displayed a M H subunit ratio of 33.13 compared to that of 78.99 in muscles
from lean mice. This was reflected by a lower proportion of LDH5 (M4; -6.8%, P<0.05) and a greater proportion of LDH4 (M1H3; +6.8%,
P<0.05) isoenzymes in EDL from obese mice. Taken together, these data suggest that the shift towards a more aerobic-oxidative muscle
observed in the present study of EDL from the obese mouse may be part of an adaptive response to the obese condition, whereby the
physiological role of the EDL muscle changes from a muscle enabling rapid movement to a muscle more suited to working under condi-
tions of increased body weight.

Oral presentations (OP)

OP-BN03 Biomechanics 3 - Neuromuscular

COMPARISONS OF THE LOWER LIMB KINEMATICS AND INTER-JOINT COORDINATION BETWEEN THREE DIFFERENT
CLOSED KINETIC CHAIN EXERCISES

Romanaazzi, M., Galante, D., Shira, Y., Sforza, C.
Università degli Studi di Milano, Italy

Introduction - Resistance exercise prescription is used to improve sport performance, rehabilitate injury, and preserve functional inde-
pendence in older adults. Despite its branching applicability, all resistance exercise prescriptions require a fundamental analysis, termed
needs analysis. Thus, appropriate resistance exercise prescription requires an analysis of both the activity to be improved, restored, or
preserved, and the exercises that may be used to the scope.

Methods - Eight healthy, young resistance training athletes (aged range 21-39 years, body weight 54-81 kg, standing height 160-176 cm)
performed three different exercises: Forward lunge (FL), Forward step-up (FSU) and Deadlift (DL) with a load corresponding to the subject's
15 RM. The three-dimensional movements of six right-side body landmarks (fifth metatarsal heads, heel, lateral malleolus, head of fibula,
greater trochanter and anterior superior iliac spine) were detected by an optoelectronic instrument with a sampling rate of 60 Hz (SMART
System - B.T.S., Milan, Italy), during 3 repetitions of each exercise (2). The lower body was modeled as 4 rigid bodies (feet, leg, thigh, and
pelvis) connected by pin joints. Angle displacement of ankle, knee and hip were obtained from the cinemematic data. To assess the interjoint
coordination during each task, continuous relative-phase variables (CRF) were calculated between pairs of joints (1). The average values
obtained over the three trials of the ankle, knee, and hip sagittal plane range of motion (ROM) angles, and average RMS value of CRF
between ankle-knee, knee-hip and hip-ankle (1) were used for statistical analysis (two-way factorial analysis of variance with repeated
measures).

Results As expected, ROM differed among the three analyzed joints, while no significant differences were found between exercises. From
FL to DL, CRF of movement coordination between ankle and knee decreased of 13° (p<0.001); from FL to FSU, CRF between knee and hip
decreased of 15° (p<0.0001). In the other instances, the level of phase coordination was similar between the exercises.

Conclusions The joint ROM did not differ among the three motor tasks. The execution of FL was made with different inter-limb motor
programs, resulting in a significant difference in ankle/knee coordination relative to DL, and in knee/hip coordination relative to FSU.
These findings should be considered when prescribing exercises, matching closed kinetic chain biomechanical attributes with the re-
storative, maintenance or improvement requirements of patients and athletes.

EFFECTS OF SUBMAXIMAL FATIGUING CONTRACTIONS ON THE COMPONENTS OF DYNAMIC STABILITY CONTROL
AFTER FORWARD FALLS

Walsh, M., Karamanidis, K., Pepper, A., Bierbaum, S., Arampatzis, A.
Miami University, United States

Several studies reported that loss of muscle strength may alter the capacity of the human system to generate rapid force for balance
corrections after sudden perturbations (3,4). In agreement to these reports, we found that the muscle-tendon capacities of the lower
limbs contribute about 33% to the balance recovery after forward induced falls (2). However, postural corrections after a sudden per-
urbation involve sensorimotor adaptational responses which include mechanisms responsible for maintaining the dynamic stability and
thus muscle weakness may be partly compensated by proper planning and execution of the used locomotion strategy. The present study
aimed to experimentally investigate the effect of muscle strength decline, induced by submaximal fatiguing contractions, on the dynamic
stability control of young adults during forward falls.

Thirteen participants (body mass: 70.2 kg, body height: 175 cm) were instructed to regain balance with a single step after a sudden
induced fall from a forward-leaning position before and after the fatigue. The experiment (pre and post fatigue) has been performed at
12 Vicon cameras operating at 120 Hz.

The reaction time as well as the duration until touchdown did not show any differences (p>0.05) before and after the fatiguing contra-
tions. All components of the dynamic stability (1) at touchdown did not differ significantly (p<0.05) between the two conditions. As ob-
served at the instant of touchdown as well as at the end of the main stance phase the fatiguing contractions had no effect on the compo-
nents of dynamic stability. In the fatigued condition, the participants flexed their knees more during the main stance phase, leading to an
increment in time available to decelerate the horizontal CM motion.

The fatigue related decrease in muscle strength did not affect the margin of stability, the boundary of the base of support or the position
of the extrapolated centre of mass during the forward induced falls, indicating an appropriate adjustment of the motor commands to
compensate the deficit in muscle strength. We concluded that the decrease in muscle strength after the fatiguing contractions do not lead
To functional deficits while the forward falls demonstrating that this specific impairment of the musculoskeletal system cannot fully predict the postural performance.

THE FORCE-RATE OF FORCE DEVELOPMENT RELATIONSHIP IN THREE TYPES OF ISOMETRIC CONTRACTIONS

Markovic, G., Knight, C., Jarić, S.
School of Kinesiology, University of Zagreb, Croatia

INTRODUCTION

When individuals are asked to produce rapid contractions to force levels along a submaximal continuum, there is a strong linear relationship between the peak force (PF) achieved and the corresponding peak rate of force development (RFD). However, a number of factors could confound the PF-RFD relationship, one of them being contraction history. The purpose of this study was to investigate the PF-RFD relationship in three different types of isometric contractions: 1) contraction from rest (REST), contraction from a 20% MVC baseline force level (BASE20), and 3) contraction preceded by a small effort in the opposite direction (PULL-PUSH).

METHODS

Twelve physically active adults (6 females) participated in the study. Subjects were seated on a custom bench for isometric testing. The left leg was affixed to a strain gauge force transducer proximal to the ankle joint. Subjects were asked to perform three MVC for the purpose of scaling all subsequent forces. Thereafter, subjects performed blocks of five contractions at each of three force levels in each of the three experimental conditions. In each condition, subjects were instructed to generate force above 40, 60, or 80% MVC, as fast as possible. Visual feedback was provided for each subject. For each force pulse, PF and RFD were recorded. In the BASE20 condition, the amplitude of individual pulses was calculated by subtracting the baseline force level from the peak force. Within each of the three conditions, five muscular contractions to each force level (40, 60, 80% MVC) provided 15 measurements. For each individual subject, as well as for the whole group, linear regression was used to describe the relationship between PF and RFD.

RESULTS

All participants had strong positive PF-RFD relationships (R2=0.66-0.99). R2 values were correlated such that consistent performance was associated with greater slopes (r=0.51, p<0.01) and lesser y-intercept (r=0.58, p<0.01). The covariance between the slope and y-intercept was very strong (r=0.94, p<0.01). When data from all subjects were consolidated within the three conditions there was remarkable similarity among the PF-RFD relationships. There were no significant differences between conditions for slope or y-intercept. Note also that our PF-RFD parameters for knee extension were strikingly similar to those reported by others for dorsiflexion.

CONCLUSION

Considering these results, and other reports in the literature, it seems that the PF-RFD relationship may represent a rule that describes the expression of the amplitude and rate characteristics in these feed-forward isometric force impulses. Our finding suggests that 1) exertion of high forces and the rapid exertion of forces represent the same ability of the neuromuscular system, and 2) separate evaluation of PF and RFD is not needed in routine testing batteries.

DYNAMIC ANTERIOR Tibial DISPLACEMENT AND Hamstrings REFLEX ACTIVATION

Bruhn, S., Schweickhardt, M., Golither, A.
University of Rostock, Germany

Introduction.

Anterior tibial displacement leads to increasing strain in hamstrings and ACL and thus induces hamstrings reflex activation. Requiring adequate dynamics of the stimulus, the hamstrings reflex activation comprises short (SLR) and medium latency responses (MLR) (Lee & Talbot, 1975). It is assumed that underlying group Ia and II signals are sensitive to different stimulus properties. Thus the aim of the study was to investigate whether variation of tibial displacement concerning the velocity and the amount of the stimulus was associated with modulation of reflex activation.

Methods.

Dynamic tibial displacement in anterior direction was applied, while the subject was standing upright with the knees slightly bent. The stimulus was induced by a falling weight and transferred to the shank of the subject. By varying the mass and the height of fall, the impulse could be varied concerning the amount of the resulting force and the rate of force development acting on the shank. The respective properties of the stimulus were measured with a force transducer and estimated by the size of the impulse (IMP), the maximal force (FMAX) and the rate of force development (RFD) acting on the shank. Tibial displacement (TD) was measured with an arthrometer. The amount of the SLR and MLR of m. biceps femoris (BF) and m. semitendinosus (ST) was calculated by integrating the EMG over time (iEMG) (Gruber et al., 2006). Correlation between the stimulus properties and the reflex activation was analyzed.

Results.

Significant correlation between the SLR of BF and the RFD acting on the shank could be detected, while IMP and FMAX did not affect SLR. MLR of BF correlated significantly with FMAX but not with IMP and RFD.

Discussion.

The results indicate, that the respective reflex components are sensitive to different stimulus properties. While the SLR is sensitive for RFD but not for FMAX and IMP, it is obvious that the underlying different contribution is of differential origin probably resulting from dynamic nuclear bag fibers. Therefore the la afferents are supposed to be responsible for the SLR not only due to the reflex latencies, but also due to their sensitivity concerning the specific quality of the stimulus. The MLR component is sensitive for FMAX and not for RFD. Thus this reflex component is supposed to be of proportional origin probably resulting from static nuclear chain fibers, which are mediated through group II fibers. Our study highlights the importance of the stimulus properties for the corresponding reflex activation of hamstrings muscles in anterior tibial displacement.

HAMSTRING THICKNESS AND STRETCH IN ISOMETRIC RAMP CONTRACTIONS
Kouvelioti, V., Makrakis, M., Kellis, E.
Aristotle University of Thessaloniki, Serres, Greece

Hamstring muscle and tendon strains are frequent injuries in various sports. Therefore investigation of tendon and muscle properties of the hamstrings is important. Chleboun et al., (2001) found that the fascicle length and pennation angle of biceps femoris (BF) changed significantly as length changed. Due to the complexity of the hamstrings, its architecture and function are affected by the change of the knee joint angle and the level of muscle force. Information on muscle architecture related to joint positions is essential for the study of muscle function (Lieber, 1993) and treatment of hamstring injuries.

The purpose of the present study was to examine hamstring muscle thickness and aponeurosis stretch during ramp isometric contractions.

**Method**
Twelve males and females performed three maximum isometric contractions (MVCs) of the knee extensors and flexors at 0°, 45°, and 90° knee flexion angle. They then performed ramp isometric contractions of the knee flexors at 0%, 40%, 80% MVC. In each position, longitudinal ultrasonic images of the BF were obtained. The video images were digitized to measure aponeurosis strain and the muscle thickness during each position.

**Results**
The results indicated that for each knee flexion angle, as the MVC levels increased, the strain values increased. Particularly the strain values ranged from 3 to 10 cm, 6 to 13 cm and 5 to 14 cm at 0°, 45°, and 90° angles respectively. The muscle thickness decreased as the MVC level increased. The muscle thickness values ranged from 2 to 7 cm, 3 to 17 cm and 2 to 10 cm at 0°, 45°, and 90° angles respectively. The above results indicate that hamstring’s tendon elasticity increases as isometric force increases via a quasi-linear relationship. This relationship could be used to model hamstring function muscle-tendon unit.

AGE-RELATED H-REFLEX EXCITABILITY AND JUMPING PERFORMANCE IN MAXIMAL DROP JUMPS
Piirainen, J., Linnamo, V., Avela, J.
University of Jyväskylä, Finland

**INTRODUCTION**
Neuromuscular activity and thus physical performance is strongly dependent on motoneuronal excitability. H-reflex, as a measure of this excitability, has been shown to be modulated during movement (1). In addition, H-reflex response in passive condition may be affected by ageing (2). It is, however, not clear whether the possible changes during movement are similar between different age groups. Therefore, the purpose of this study was to examine the possible effect of ageing in H-reflex activity and jumping performance in maximal drop jumps (DJ).

**METHODS**
10 young (Y: 21-31 years) and 20 elderly (E: 60-70 years) males participated in this study. H-reflex and M-wave were measured from the soleus muscle (Sol) during standing rest and during maximal drop jumps (DJ). In DJ the onset of the H-reflex stimulation was 20ms after ground impact. Hmax/Mmax -ratio was calculated for standing and H/M20% -ratio for DJ. In DJ, take-off velocity and pre-, breaking- and push-off phase EMG (RMS) activity was measured from Sol and medial gastrocnemius (MG) muscles. EMG values were normalized to maximal EMG which was measured during maximal isometric plantar flexion (MVC).

**RESULTS**
Take-off velocity was significantly higher in young (Y: 2.47 ± 0.09 m/s, E: 2.05 ± 0.16 m/s, p<.001). Pre-activity EMG was significantly higher in elderly only in MG (Y: 38.4 ± 32.5%, E: 82.9 ± 32.8%, p<.01). EMG in the breaking phase (Y: 79.1 ± 46.7%, E: 51.4 ± 17.3%) and in the push-off phase (Y: 165.8 ± 46.9%, E: 128.5 ± 32.7%) were significantly higher (p<.05) in young, but only in Sol. Hmax/Mmax -ratio in standing did not differ between the two groups (Y: 0.37 ± 0.25, E: 0.34 ± 0.18) and no statistically significant age-related changes were found in H/M20% -ratio during DJ (Y: 0.97 ± 0.91, E: 0.78 ± 0.50). MVC was almost similar in both groups (Y: 181 ± 15Nm, E: 178 ± 46Nm).

**DISCUSSION**
Decreased take-off velocity and breaking and push-off phase activity during DJ indicate decreased muscle performance of the elderly. Surprisingly, similarly to MVC, no significant differences in Hmax/Mmax ratio either in standing or in DJ condition could be observed between the age groups. Ageing has been shown to lead to degeneration of the fast twitch motor units (3). As soleus muscle consists mainly of slow type motor units, the effect of ageing for that particular muscle could be lower. This could probably explain why only small differences in H-reflex excitability between the age groups were observed.

Multilevel Poisson Regression model was fitted to assess Rate Ratios and 95% CI, predicting the number of clustered risk behaviors.

The distribution of CRP was positively skewed. The median value was 0.42 mg/L in girls and 0.66 mg/L in boys. A total of 11.1% in girls and 10.3% in boys had levels above 3 mg/L (p=0.340), a threshold defining the adult high-risk category. CRP was strongly related to BMI (r=0.584, p<0.0005), waist circumference (r=0.603, p<0.0005) and sum of skinfolds (r=0.656, p<0.0005). CRP exhibited strong positive correlations with triglycerides (r=0.402, p<0.0005), total cholesterol/HDL-cholesterol ratio (r=0.371, p<0.0005) and Apo B (r=0.284, p<0.005). These relationships remained unchanged after adjustment for obesity. Other factors were either not related to CRP (blood pressure, total cholesterol, Apo A1, Iqpal, adiponectin, TNF-α) or their correlation was markedly attenuated to statistically non-significant levels after adjustment for obesity (glucose, LDL-cholesterol, HDL-cholesterol, LDL-cholesterol/HDL-cholesterol, Apo B/Apo A1).

Discussion/Conclusion.
CRP was positively correlated with most cardiovascular risk factors. However, with the exception of triglycerides, total cholesterol/HDL-cholesterol ratio and Apo B, the correlations were largely explained by the confounding effect of obesity, emphasizing the many effects of obesity on body metabolism. The independent relationships with triglycerides, total cholesterol/HDL-cholesterol ratio and Apo B suggest a role for inflammation throughout life in the development of cardiovascular and metabolic derangements. Our findings suggest that it may be important to control body weight to prevent an increase in serum CRP in Greek children.

Results
Correlations were used to test the interrelationships among CRP, obesity and cardiovascular risk factors.

Methods
The sample comprised 5723 women, aged 36.8 ± 9.1 who participated in the APAHS. Physical activity (PA) was assessed with the International Physical Activity Questionnaire short version (IPAQ). Total PA was expressed as minutes/week, by weighting the reported minutes of moderate PA and vigorous PA per day, by the number of days of each type of PA (Total PA = moderate-intensity activity minutes x moderate-days + vigorous-intensity activity minutes x vigorous-intensity days). Subjects were classified as inactive if total PA <= 150 minutes of moderate PA and vigorous PA per day, by the number of days of each type of PA.

Results: Results showed that the prevalence of physical inactive women was 55.6%, 52.3% had a BMI >= 25 kg/m2, 18.5% were current smokers and 72.4% had an inadequate sleeping time. The risk behavior combination with higher prevalence was "physical inactivity, inadequate sleeping time and BMI=> 15 Kg/m2" - 21%. Inactive women were more likely to have 1 risk factor (x2= 31.585, p<0.001) and 2 risk factors (x2= 36.197, p<0.001) but were less likely to have 3/4 risk factors (x2= 4.731, p<0.001) compared to active women. Regression analysis showed that physical inactivity was not a predictor of the number of clustered risk behaviors, after adjusting for age and education level (Rate Ratio=0.9782; 95%CI: 0.939-1.019, p=0.051).

Conclusions: Among Azorean women, physical inactivity was not a predictor of the number of clustered risk behaviors, although having 1 or 2 risk behaviors was associated with physical inactivity (in the bivariated analysis). Further studies are necessary to investigate and clarify this relationship between physical inactivity and risk behaviors, in this population.
FLEXIBILITY IS FITNESS RELATED TO ARTERIAL STIFFNESS

Yamamoto, K., Kawano, H., Gando, Y., Iemitsu, M., Murakami, H., Sanada, K., Tanimoto, M., Higuchi, M., Tabata, I., Miyachi, M.
Waseda University, Japan

PURPOSE: Fitness, especially cardiovascular endurance, has been identified as determinants of age-related arterial stiffening. Health-related components of fitness include cardiovascular endurance, muscular strength and endurance, and flexibility. Although the flexibility of different components of fitness, the relationship between flexibility and arterial stiffness remains unknown. Using the cross-sectional study design, we tested hypothesis that the flexibility associated with arterial stiffness independent of other components of fitness. METHODS: A total 314 adults, 20 to 39 years of age (young), 40 to 59 years of age (middle-aged) and 60 to 77 years of age (older), who were either poor-flexibility or high-flexibility, were studied. The flexibility was evaluated by sit-and-reach test. Cardiovascular endurance and muscular strength were measured by peak oxygen uptake and leg power, respectively. The arterial stiffness was assessed by brachial-ankle pulse wave velocity (baPWV). RESULTS: In young group, the sit-and-reach values of poor-flexibility and high-flexibility were 35.0 +/- 6.2 and 47.9 +/- 5.2 cm, respectively (P<0.001), those in middle-aged group were 32.1 +/- 5.3 and 45.9 +/- 4.9 cm, respectively (P<0.001), and those in older group were 27.1 +/- 6.5 and 42.2 +/- 5.0 cm, respectively (P<0.001). In each age group, age did not differ between poor-flexibility and high-flexibility groups. In older group, baPWV was higher in poor-flexibility than in high-flexibility peers (F=542 +/- 245 vs 1361 +/- 202 cm/s, P=0.01). However, in young and middle-aged groups, there was no significant difference between two flexibility groups. In the pooled analysis, a univariate regression analysis indicated that baPWV correlated with sit-and-reach (r=0.34, P<0.0001), peak oxygen uptake (r=0.42, P<0.0001) and leg power (r=0.19, P<0.001). A stepwise regression analysis revealed that among components of fitness, sit-and-reach and peak oxygen uptake were independent correlate of baPWV. Leg power did not enter as significant predictors of baPWV. CONCLUSION: We concluded that (1) poor-flexibility was associated with the higher arterial stiffness in older group, (2) age-related arterial stiffening was greater in poor-flexibility than in high-flexibility, and (3) flexibility independently associated with arterial stiffness. These findings are consistent with the idea that flexibility is identified as determinants or predictors of age-related arterial stiffening independent of other components of fitness.

CHARACTERIZATION OF A SEVEN MINUTES AQUATIC EXERCISE MAXIMUM EFFORT AND HEALTH RISK DETERMINATION

FADEUP, Portugal

Literature on hydrogymnastics is scarce and has been situated mainly on the estimation of aerobic performance indicators. According to the guidelines of the ACSM (Haskell et al., 2007) healthy adults need moderate-intensity aerobic physical activity. Anaerobic performance development as been neglected in fitness field without any sustained reason. Apparently, this kind of efforts still needs to be studied and possible health risks associated to it should be assessed. The aim of the present study was to characterize a long effort peak and detect possible health risk factors associated with it. Ten healthy women (38.3 +/- 9.39 years) experienced in hydrogymnastic participate in the study. Exercise protocol consisted on a 3 min warm up (level 11 in Borg’s 6 to 20 Rate of Perceived Exertion (RPE) Scale), followed by 5 min of aerobic exercise of moderate intensity (13 to 15 in Borg’s RPE scale), and a peak effort (18 to 20 in Borg’s RPE scale) of 7 min duration. Rest HR values (POLAR Vantage NV™) were obtained both on land and in water and during exercise. Blood pressure (BP) was evaluated at rest, and after exercise by experienced health professionals using a sphygmomanometer and a stethoscope. Mean BP was also calculated using systolic (SBP) and diastolic blood pressure (DBP) (MBP=1/3 SBP-DBP+DBP) and used as a health risk factor. Blood lactate concentration ([La-]) was determined at rest and after exercise (LactatePRO). Due to the lower number of subjects studied, both non-parametric Wilcoxon test and parametric Paired Samples T-Test were applied to data. The level of significance was established on 5%. Differences obtained trough both statistical procedures leaded to the same results. HR rest values were significantly lower on water (69.9 +/- 11.06 bpm) comparatively to land (75.7 +/- 11.63 bpm). Peak and mean HR values of the 7 min peak were 185.3 +/- 11.54 and 179.90 +/- 12.81 bpm, respectively. After exercise systolic blood pressure was significantly higher (mean difference of 26.40 +/- 15.02 mmHg) and diastolic blood pressure was significantly lower (mean difference of 5.00 +/- 4.9 mmHg) than at rest. The same MBP was observed in rest (88.8 +/- 12.22 mmHg) and after exercise (83.4 +/- 14.41 mmHg), showing a lower cardiovascular risk associated to an exercise performed at maximum intensity during a relatively long period of time. [La-] values were significantly higher after exercise (12.0 +/- 3.40 mmol/l) comparatively to rest (0.8 +/- 0.1 mmol/l) and showed the high level of participation of the anaerobic metabolic pathway during the 7 min peak. BP and [La-] values combined leads to the conclusion that anaerobic exercise could be safely used in hydrogymnastic classes with healthy subjects.

PHYSICAL-ACTIVITY AND HEALTH IN A CROSS-SECTIONAL POPULATION STUDY AND THE EFFECT OF SUBSEQUENT WORKSITE INTERVENTIONS WITH CONTRASTING PHYSICAL-EXERCISE PROGRAMS ON SPECIFIC HEALTH OUTCOME MEASURES

Sjøgaard, G., Pedersen, M., Blangsted, A., Andersen, L., Jørgensen, M., Hansen, E.
University of Southern Denmark, Denmark

Background: Physical activity is known to have a positive effect on metabolic, cardiovascular, and musculoskeletal health as repeatedly documented in cross-sectional population studies. However, conflicting results have been reported in randomized controlled interventions in particular in regard to musculoskeletal health. Also, previous studies have been unsuccessful in discriminating the effectiveness of different types of exercise interventions in relation to various health outcomes. Aim and Methods: A cross-sectional population study was conducted at a public work place (N=2000 employees) followed by a one-year worksite randomized controlled physical-exercise intervention (N=600 employees) with three groups: specific resistance training (SRT), all-round physical exercise (APE), and reference (RE) without physical exercise programs. The aim was to analyse at baseline for possible relationships between physical activity and various health outcomes in terms of self-rated general health, frequency of musculoskeletal health including muscle strength, and measured variables on risk indicators for metabolic and cardiovascular health (i.e. blood pressure, body mass index, body fat percentage, and maximal oxygen uptake). The same measures were taken mid and post interven-
tion. A questionnaire was filled in with regard to general health, duration and intensity of musculoskeletal pain and physical activity. The risk indicators were measured by conventional methods.

Results and Discussion: At baseline there were significant correlations between participants physical activity and self-rated general health (R=0.09 for total physical activity and R=0.12 for vigorous activity). Further, significant correlations were found between vigorous activity versus neck pain (R=0.11), shoulder strength (R=0.10), body fat percentage (R=0.09), and maximal oxygen uptake (R=0.13). These data are in concert with previous studies. Worksite exercise interventions (APE+SRT) relative to REF intervention had positive effects on musculoskeletal pain in neck and low back (duration of pain during the last three month was reduced ~ 25%) as well as on shoulder strength (increased ~10%). But only SRT showed a preventive effect on neck pain. Likewise, exercise decreased body fat percentage (~5 percent point) and systolic blood pressure (~5mmHg), but only APE showed significant improvement in maximal oxygen uptake. No changes occurred in the REF group.

Conclusion: Physical activity correlated with several positive health outcomes regarding musculoskeletal as well as metabolic and cardiovascular health; vigorous activity showing the strongest correlations. Different types of physical-exercise at the worksite showed a number of similar health enhancing effects; however, results showed SRT to be superior regarding prevention of neck pain while AET was superior regarding an improved health risk indicator for metabolic and cardiovascular health. Thus, effectiveness of different types of exercise interventions was demonstrated to be specific in relation to promoting various health outcomes.

CARDIOVASCULAR RISK FACTORS IN RECREATIONAL FOOTBALLERS: A MATCHED CASE-CONTROL STUDY

Impellizzeri, F., Maffulli, N., Bizzini, M., Wisloff, U., Carlomagno, D., Dello, A., Castagna, C.
Schulthess Clinic, Switzerland

INTRODUCTION: Low levels of cardiorespiratory fitness, altered blood lipid profile and blood pressure are associated with high risk of cardiovascular diseases and all-cause of mortality. However, regular exercise and physical activity have favourable effects on cardiorespiratory fitness. Therefore, the increase of physical activity at all levels is considered a priority by all the national and international Health Organizations. Association football (soccer) is the most popular sport in the world. Several studies have examined various aspects of football but the majority of these have studied football in a competitive context. However, millions of people are involved in football at a recreational level and therefore this sport may be an effective exercise modality to enhance aerobic fitness and reduce cardiovascular risk factors. Surprisingly, very few studies or reports (Castagna et al, JSaMS, 2006; Krustrup et al., BASES congress, 2007) have examined football from this perspective. We designed this matched case-control study to examine differences in selected cardiovascular risk factors between recreational footballers, participants to structured aerobic training programs and untrained subjects. METHODS: After matching for age and activity level (IPAQ), 31 football players (FB: age 37±7 years, BMI 23.9±2.4 kg/m2) were compared to 31 participants to aerobic training programs (AE: 38±6 years, BMI 24.2±2.4 kg/m2) and 62 healthy untrained people (UN: 39±6 years, BMI 25.9±2.3 kg/m2).

Maximal oxygen uptake (VO2PEAK) and oxygen uptake efficiency slope were measured during maximal incremental cycling tests. Blood pressure and lipid levels (total cholesterol, HDL-C, LDL-C, triglycerides, and fasting glucose) were also measured. RESULTS: UN showed higher body mass (~7%), body fat (~27%) and BMI (~28%) than AE and FB (P<0.01). UN also showed lower maximal oxygen uptake (~16%) and oxygen uptake efficiency slope (~11%) than AE and FB (P<0.001). No differences between groups (P>0.32) were found in blood pressure or lipid profile, with the exception of triglycerides that were higher in UN (~20%) (P=0.02). The corresponding metabolic equivalents (3.5 ml/kg/min, MET) for the VO2PEAK in FB, AE and UN were 10.7, 11.0 and 9.1 MET, respectively. DISCUSSION: Cross-sectional and longitudinal studies have shown that every 1 MET increase during incremental tests is associated with a 8 to 14% reduction in mortality. In the present study the higher VO2PEAK in FB and AE corresponded to a difference of 1.6-1.8 MET. No substantial differences were found in blood pressure and lipids data (with normal ranges in all groups). However, even when other risk factors are taken into account, aerobic fitness remain a strong and independent predictor of mortality. In conclusion, the findings of this study suggest that recreational football has the potential to be an effective health-enhancing physical activity.

OP-PH01 Philosophy

BODY AND MOVEMENT PHENOMENOLOGY

Hogenova, A.
Charles University, Czech Republic

This reflection wants to point out that there is a connection between performance adoration and objectivization of the body. What does it mean for movement, for the human existence? Existence is the most complex movement of all, we always head for a goal (telos), we proceed from the beginning of the mobility (archê). While doing so, we enter situations that we have not chosen. The pressure of such situations forces us to choose an option (dynamis) that tries to solve the situation. The transition from the option to reality is called energeia. This results in a deed (ergon).

A sports movement always involves telos, archê and dynamis. If performance becomes the only goal, options and sometimes even the beginning of mobility adapt themselves to this telos. This transformation is a dangerous one. The body adapts itself to the top performance, too; it becomes an object. What will happen when the body is transformed in a tool which is entirely controlled by the will to achieve top performance? Situations and their demands will be absolutely subordinated to the desire to achieve performance, i.e. all bans will be understood as something that must be circumvented.

Orexis intention and desire to move forward is controlled and determined by the will to such an extent that objectivized body becomes an impassable obstacle, after that, the orexis will burn out, too. The doctor will encounter anaesthesia, for instance. However, the root of the problem is the body as an object with which the owner may do what he/she wants. Nevertheless, the body as an exclusive object is the result of performance adoration. And this is typical of the sports world. What must be done so that the sports performance becomes a celebration of humanity? How to train teachers, trainers and coaches?

References:
A major objective of both sports scientists and elite coaches is the enhancement of sport performance. Despite this common goal, there is a general perception that research in sports science does not meet the needs of coaches (Williams and Kendall, 2007 b). In the literature on coaching, several authors refer that exist a “gap” between sports science research and coaching practice (Spinke, 1997; Goldsmith, 2000; Williams and Kendall, 2007 a, b and Midgley et al., 2007). Under the scope of contributing to minimise the “gap” between research and coaching practice, specially referring to physiologic factors that impair sport performance, this work aims to (1) identify some major problems that impair the use of physiologic factors in sport training and (2) propose solutions to the identified problems. The major problems identified were (i) the disciplinary research and the over specialization; (ii) lack of understanding the sport activity characteristics; (iii) the different conceptions of body and human movement and (iv) data overflow, from coach point of view. Solutions for each of the major problems identified are pointed out, in attempt to approach sport science researchers and coaches: (i) understand the complexity of “real world” problems of coaching practice; (ii) improve the knowledge about sport activities, to understand the different kind of solicitations that are imposed to the athlete; (iii) develop integrative frameworks to the training process, that comprehend the different factors that affect sport performance and (iv) develop operative methodologies that allow to select, evaluate and apply the most important data to improve the sport training process. In conclusion, operative researches, that comprehend the complexity of sport performance phenomena are missing, what may reflect an undervaluing of the benefits of scientific knowledge, by the coaches (Williams and Kendall, 2007 b).

NEUROSCIENCE, REDUCTION, SPORT AND PHILOSOPHY OF MIND

Birch, J.
Norwegian School of sport science, Norway

The rapid progress of biology and genetics at the molecular level, combined with the advance of better neuroimaging-techniques like fMRI, PET and EEG make great leaps toward understanding and explaining relationships between brain, behaviour and mind. Do we see the rising of a Grand Universal Theory? Finding not only correlation, but arrow-pointed causality? Are we about to find the mechanism underlying all kinds of memory necessary for learning? Will our understanding of skillacquisition change in light of how neural pathways develop during childhood and life? Training methods, pedagogy, psychology and bio-mechanical approaches to the understanding of sporting practices might have to change due to new neuroscientific discoveries. Or, at least, get a better platform to do empirical research and experiments. The talk takes a philosophical look at the reductions made by the neurosciences. I will claim there is an ex-planatory gap between reductions in the neurosciences and the subjective experiences of everyday life. This gap can in principle not be closed. There are several reasons for this. First, the neurosciences deal with third-person objective observations - subjective experiences are first-person experiences. First-person experiences cannot be reduced to third-person without losing a fundamental aspect, which the third-person reduction wants to explain; the subjective experiential aspect. Second, the personal mental language of persons cannot be reduced or substituted by the objective language of the neurosciences (molecular or cellular), because our common language is based on semantic content not provided by physical descriptions. Third, to have an objective look inside our own mind requires a view from nowhere. The view from nowhere cannot be established when it involves looking at ourselves; there is nowhere we can build the fundament of a pure, objective eye that can look without values or preferences and report back to us in the same objective way. The talk will clarify that the experiential aspect of mind is an important one in sport. Practising sport has a fundamental phenomenal feeling to it, and this is not reducible in neuroscientific terms (or in any other physical language for that matter). That is not to say that the discoveries of the neurosciences are not interesting. They may provide us with insights when it comes to, let's say, memory and learning. But a full-blown account of brain, body and mind relations is not arising. One must have all the experiences of the subject in question to do this. That is in principle, impossible.

To paraphrase Thomas Nagel (1): to have a complete understanding of what it is like to be a bat, one must be a bat. This is also true for sport, the experiential aspect of actually moving cannot be accounted for by the neurosciences. No matter what they promise.

THE ROLE OF CONSCIOUSNESS IN ELITE SPORT

Breivik, G.
Norwegian School of Sport Sciences, Norway

Philosophy of mind has become the central discipline in modern philosophy. The development in cognitive science, neuropsychology and computer science has created a fertile cross-disciplinary ground where many of the old problems can be raised in a totally new setting. One of the central topics is the role and place of consciousness. Increasingly philosophers accept that the subjective experience of the conscious mind must be taken seriously and that the hard problem today is to explain how it is possible that experiential qualia, the feeling of what it is like to have some experience, can arise out of soggy grey matter. The soft problem is easier to address; how mind states are linked to and located in specific brain areas.

Phenomenology has also received new attention and has been combined with new findings from psychology and brain research. Dreyfus (2002) has developed a model with five stages that tries to describe how skills develop from novice to expert level. Dreyfus maintains that whereas consciousness plays a central role at beginner’s level it plays no role at expert level. The information-processing model in...
motor learning says similarly that beginners process information in a conscious manner and according to rules. At more advanced levels the rules and the processing are increasingly rendered unconscious. Searle (2004) who criticizes both the computer model and phenomenology also maintains that at high skill levels the athletes just act without following rules or conscious representations. There thus seems to be strong support for a view that has as a consequence that there is little or no room for conscious thinking in elite sport. My aim in this paper is to show that this view does not hold. Elite athletes do not act like zombies. They use conscious states whether they are perceiving, thinking, deciding or acting. I will use examples from elite sport to illustrate and argue for my views. Following Chalmers (2006) I make a distinction between psychological consciousness and phenomenal consciousness. Psychological consciousness is the psychological machinery, which makes us capable of perceiving, having beliefs and desires, handling information, making decisions, and so on. Phenomenal consciousness is our experience of what it feels like, the qualitative aspect of the various mental states. When we are active in sports we always have psychological consciousness and most of the time we also have phenomenal consciousness. Through examples from different types of sport I will argue for a view that gives conscious awareness, thinking and decision a more important role than many of the dominant theories today.

THE VALUES AND ATTITUDES OF YOUNG ELITE ATHLETES TOWARD PERFORMANCE ENHANCING DRUGS

Bloodworth, A., Calitri, R., McNamme, M.
Swanse University, United Kingdom

There is evidence of a small but significant proportion of children and adolescents engaging in doping practices. Recent USA-based review articles suggest between 3 and 12 per cent of adolescent males have used anabolic-androgenic steroids at some point. (Yesalis and Bahrke 2000) while others present figures of between 4-11 per cent (Calfee and Fadale, 2006). There are few studies, however, that have explored young elite athletes’ attitudes toward performance enhancing substances in any great depth. A total of 24 young male and female athletes (16-22 years) attended 7 focus groups held over the UK. Athletes were assured of anonymity and confidentiality and that the research contractor (UK Sport) was unaware of their attendance. Discussions centred upon certain central themes: (i) the extent of a doping problem; (ii) distinguishing between banned substances and supplements and between therapy and enhancement; (iii) ‘Tipping points’ in the decision to dope, and (iv) willingness to take a banned but undetectable performance enhancing substance that would guarantee success. Participants also completed an implicit (ID-EAST, De Houwer and De Bruycker, 2007) and explicit measure of their attitude toward doping and supplements.

Athletes from 9 different sports participated in the focus groups. Knowledge of doping techniques was limited. Doping was often associated with appearance altering drugs such as anabolic-androgenic steroids. The economic implications of falling at an elite level were cited as a potential ‘tipping point’. A significant minority of athletes indicated their willingness to use a non-detectable, banned drug that would guarantee success. Interestingly, however, the added condition that the drug would reduce life span by 10 years resulted in the majority of those previously willing rejecting the hypothetical opportunity.

A number of key findings emerged from the experiment examining the implicitly and explicitly assessed attitudes. There was a general trend for a positive implicit attitude toward doping. There was a dissociation between implicitly and explicitly reported doping attitudes. Implicitly and explicitly assessed attitudes toward supplements were, however, significantly associated. Despite publicly expressing negative attitudes toward doping, this group of individuals, privately, viewed doping in a somewhat positive light. Such findings place a question mark over whether there should be a reliance on explicit measures to index attitudes toward doping.

THE PHILOSOPHY OF SPORT GOES EUROPEAN

Müller, A.
Maastricht University, Netherlands

The Philosophy of Sport (1, 2), is still a more or less neglected discipline, not only within the European College of Sport Science (ECSS) but also in the field of sport science in general. Thus it is surprising that besides the well established International Association for the Philosophy of Sport (IAPS) and its growing junior partner the ‘British Philosophy of Sport Association’ (BPSA) very recently the European Association for the Philosophy of Sport and Movement Culture came into being. While a number of sport scientists are mainly aware of sport philosophy in association with the doping debate, i.e. ethical reflections on enhancement a.s.o., the philosophical spectrum has a lot more to offer sport related analyses with a focus on e.g. aesthetics (3), ethics (4), metaphysics (5), existentialism (6) etc. Hence in this paper I would like to introduce the variety philosophical aspects within sport and sport science, as well as the possibility for its (practical) application in the sense of an applied philosophy of sports (e.g. philosophic/ethic counseling, etc.) and the future perspective and aims of the European Association for the Philosophy of Sport.

anxiety before games than the Canadians, but both the Canadian and German participants perceived their anxiety as more facilitative.

MANOVA and independent samples t tests revealed that the German players had significantly lower levels of cognitive and somatic state anxiety than those in Japan. In addition, the Japanese players reported higher levels of pre-game guilt, shame, humiliation, placidity, and modesty, pleasant emotions, unpleasant emotions, and both the intensity and direction dimensions of cognitive and somatic state anxiety.

Stepwise linear regression indicated that the Country variable was related to players' stress and coping effort, and that the Type of passion was also a predictor of stress and coping effort. In line with expectations, paths linking a positive mastery climate, harmonious passion and obsessive passion to stress and coping effort were observed. Current findings illustrate the value of combining tenets of achievement goal theory (Nicholls, 1989) with the integrative sequence model of passion (Vallerand et al., 2006). However, the study findings also demonstrated the need for re-specification of the passion scales noticeably based on the positive relation found between obsessive passion and subjective vitality. Within the context of youth soccer, there is a need for further validation of the concepts of harmonious versus obsessive passion (Vallerand et al., 2006).

Types of passion were investigated in relationship to motivational climate and subjective vitality in youth soccer. Participants were 283 experienced young soccer players (aged 12-16 years) taking part in the Norway Cup soccer tournament 2004. Confirmatory factor analysis was conducted to examine the construct validity of the harmonious and obsessive passion constructs, and Structural Equation Modeling analyses were utilized to test hypothesized paths between predictor, mediator and outcome variables. Subjective vitality was positively predicted by a mastery climate, harmonious passion and obsessive passion. In line with expectations, paths linking a positive mastery climate, harmonious passion and subjective vitality were also observed. Current findings illustrate the value of combining tenets of achievement goal theory (Nicholls, 1989) with the integrative sequence model of passion (Vallerand et al., 2003). However, the study findings also demonstrated the need for re-specification of the passion scales noticeably based on the positive relation found between obsessive passion and subjective vitality. Within the context of youth soccer, there is a need for further validation of the concepts of harmonious versus obsessive passion (Vallerand et al., 2006).

essy, while the Canadian players felt the highest level of pre-game excitement. The results set apart the players of each nation, and the status of university sport is offered as a means of accounting for the Canadian and German findings. The results also reinforce popular notions of a collectivistic Japanese mentality and that this mindset may extend to intercollegiate sports competitors. For practicing intercollegiate soccer coaches and/or coaches in multicultural settings, this information can help inform the development of team motivational climates that reflect the cognitions and motivational orientations of players. For applied sport psychologists, it should allow for more relevant counseling when helping coaches and culturally diverse athletes to meet their goals.

THE PSYCHIC REALITIES OF A COACH-ATHLETE DYAD AND THE DEPLOYMENT OF DEFENCE MECHANISMS

Sellaris, C.
University of Wolverhampton, United Kingdom

Coach-athlete relationships are central to effective performance and psychological well-being in sport, yet their study has been methodologically limited. Within sport psychology, there is a recent expanding interest in coach-athlete relationships (Poczwardowski et al., 2006). Since Wylie et al.'s (2000, p.53) contention that such a focus of inquiry was ‘uncharted territory’, some researchers have begun to examine this relationship from a variety of theoretical positions. This study involves the application of a social psychoanalytic approach to the study of coach-athlete relationships and asks specifically what defence mechanisms, identities and subject positions are present when a coach and athlete describe their experiences of working in a close dyadic relationship.

A male triathlon coach (Brian) and one of his male athletes (Mack), were interviewed using a free association narrative interview (FANI) technique to elicit narratives of being in this dyadic relationship. A follow-up interview was conducted with each participant to elaborate on those areas raised by participants in the initial interview. Clarke (2002) suggests the FANI produces raw material from which one can then: identify patterns of experience and response, analyse the issues of main concern (here, facets of the coach-athlete relationship), and identify the unconscious mechanisms, expressed both within the responses to the researcher and the material described by the participant. The psychoanalytic position posits individuals may unconsciously adopt particular positions in their discourses in order to protect against anxieties emanating from vulnerable aspects of the self (Hollway & Jeffeson, 2000). Employing this approach, interview data along with associated field and reflexive notes were analysed to identify and illuminate the subject positions and defence mechanisms adopted by the participants.

Analyses of interviews revealed a number of themes: the reluctant sportsman, his pioneering spirit and relationships with his birth family (Brian) and Mack’s sporting heritage and his army discipline. Brian and Mack both displayed sporting identities, although the subject positions within their narratives were distinct, a variety of defence mechanisms (introjection, projection and objectification) were also evident and these are discussed and illustrated via appropriate quotations. The paper concludes with comment on the potential and limitations of this approach.

THE STRUCTURAL AND PREDICTIVE VALIDITY OF A VISION, SUPPORT, CHALLENGE MODEL OF TRANSFORMATIONAL LEADERSHIP

Arthur, C., Hardy, L.
Bangor University, United Kingdom

This paper presents 3 studies that test the structural and predictive validity of a three factor, vision, support, and challenge model of transformational leadership (Bass, 1985). Hardy, Arthur, Jones, Shariff, Munnoch, Isaacs, and Allsopp. In press) study used a vision, support, and challenge model of transformational leadership to underpin a successful intervention. The current study sought to examine the structural and predictive properties of the proposed model. The research was conducted with infantry recruits in a military training organization. Study 1 (n = 573) used confirmatory factor analyses in an exploratory manner to define the concepts of vision, support, and challenge. After minor modifications the conceptual model appeared tenable (S-B 2 (87) = 177.61, RMSEA = .04; CFI = .98). Using a second sample, Study 2 (n = 693) confirmed the factor structure obtained in study 1 (S-B 2 (87) = 300.87, RMSEA = .05; CFI = .98). A subset of the Study 2 sample was used in Study 3 (n = 248) to examine the predictive validity of the vision, support, and challenge model. The outcome variables selected were leader inspires extra effort, satisfaction with training, and self-confidence. Regression analyses revealed that vision, support, and challenge significantly predicted variance in leader inspired extra effort (R2 = .535, p < .001), inspection of the beta coefficients revealed that vision (beta = .317, p < .001), support (beta = .414, p < .001), and challenge (beta = .313, p = .005) all made significant contributions to the prediction. Vision, support, and challenge significantly predicted variance in satisfaction (R2 = .258, p < .001), however, inspection of the beta coefficients revealed that only vision (beta = .335, p < .001) and support (beta = .207, p = .013) significantly contributed to the prediction. Vision, support, and challenge significantly predicted variance in self-confidence (R2 = .414, p < .001), however, inspection of the beta coefficients revealed that vision (beta = .331, p < .001) was the only behaviour that significantly contributed to the prediction. The results of all three studies are discussed from a leadership and coaching perspective.

AN EXPLORATION OF PSYCHOSOCIAL COMPETENCIES IN ELITE YOUTH TALENT DEVELOPMENT ENVIRONMENTS

Swindells, M., Lovell, G., Cotterill, S., Crone, D.
University of Gloucestershire, United Kingdom

Contemporary research literature within the field of youth talent development has unequivocally supported the notion for interactional or multi-dimensional perspectives, incorporating a number of influences under the concept of psychosocial competencies. Holt and Dunn (2004) devised a grounded theory of the psychosocial competencies associated with success in elite adolescent level soccer.
The present study attempts to establish the transferability of Holt and Dunn’s grounded theory of psychosocial competencies across participants in a talent development environment (TDE) in a different sport, namely athletics. Participants were recruited through a structured TDE in the sport of athletics, numbering 6 athletes with an age range of 14-19 years. Leading on from this, selected parents (n=4) and coaches (n=2) were interviewed utilising a similar interview structure to enable triangulation of opinions on the effective requirements of TDEs, and how this corresponds with and validates Holt and Dunn’s grounded theory of psychosocial competencies across different sports. The sample of parents consisted of both mothers and fathers, to take into account findings by previous research indicating differences in type of social support provided by either parent (Bloom, 1985, Holt & Dunn, 2004). These data provided a triangulation as suggested by previous studies into social support processes.

The design of the semi-structured interviews conducted with athletes, parents, and coaches was directly modelled around the four identified psychosocial competencies of commitment, discipline, resilience, and social support. As conducted in Holt and Dunn’s (2004) study, each of the four competencies was further divided into sub-categories allowing further guidance as to the semi-structured interview questions. Collected and transcribed data were subjected to a process of thematic analysis and examined for emerging themes establishing the general dimensions of the four key identified psychosocial competencies. Constructing the methodology in such a manner, staying close to the original model of Holt and Dunn (2004), allow the findings to be a truly applicable representation of the original grounded theory and its generalizability across other sports and TDEs. This will therefore result in facilitating a coherent development of the original model, and progression of the body of knowledge.

The findings from participants are drawn together in relation to applied sport psychology implications, and the interactional nature of social support and athletes psychosocial competencies within TDEs. Directions for further research within the area are suggested.

OSGOOD-SCHLATTER’S DISEASE: AN ACTIVE APPROACH USING MASSAGE AND STRETCHING
Strickland, J., Coleman, N., Brunswic, M., Kocken, R.
University of Greenwich, United Kingdom

Introduction: Osgood-Schlatter’s disease (OSD) is a traction apophysitis of the tibial tubercle of the knee and tends to affect athletically active adolescents during their secondary growth spurts. It is a painful and extremely limiting condition and is the most common overuse injury in this age group. The current standard treatment is to allow the athlete to self-manage pain and activity levels, but the documented history of this condition records patients having to refrain from physical activity for an average of 21 months. The object of this pilot study was to investigate the dual influence of myofascial release massage (MRM) and stretching of the quadriceps group on the speed of recovery of patients with OSD.

Method: 25 patients were referred for physiotherapy treatment for OSD (6 female, aged 11.6 ±1.55 SD; 19 male, aged 13 ± 1.6). Onset of symptoms ranged from acute (1 week) to chronic (36 months) with an average of 8 months. Initial measurements of functional tendon loading using a standing wall slide test were taken for all subjects. This test was then repeated at regular intervals. MRM was performed daily for 2 minutes, either by the physiotherapist or parent who had been taught the technique. Once pain free knee flexion was achieved, active stretching was then performed daily by the patient instead of the MRM. Statistical analysis was performed to determine any significance between subsequent recordings using one-tailed t-tests.

Results: All patients achieved a full wall squat in an average of 20 days (±12) with a maximum of 50. The improvement in wall slide was significant to 98% (p<0.02) for each recording. Upon full wall slide patients were discharged and returned to their sporting activities as normal, with no reported further problems. At various follow-up dates (1-5 years) only 2 patients reported recurrence but they had not followed the recommended advice on stretching.

Discussion: In spite of the vagaries of adolescent and parent compliance, and the limitations of clinic appointments, these results indicate that MRM and stretching are likely to be an important intervention in the active treatment of this disabling condition. The patients in this study returned to their sport in a significantly shorter time than is usually anticipated with the traditional ‘let them grow out of it’ approach.

Keywords: Osgood-Schlatter, adolescent, knee injury, massage, stretching, apophysitis

THE INFLUENCE OF KNEE PAIN ON GROUND REACTION FORCES DURING SSAIR ASCENDING AND DESCENDING
Pais, S., Espanha, M., Santos, M., Silva, C., Cruz, S.
CIFER, Faculty of Human Kinetics, Technical University of Lisbon, Portugal

Introduction: Patients with knee Osteoarthritis (OA) report knee pain during daily living activities and consider this to limit their ability to perform these tasks (1). Several activities such as going up or down stairs are important for subjects to maintain autonomy. It is known that, besides walking slower patients with severe OA need more time to go up and down a flight of stairs than normal subjects (2, 3). This study was conducted with bilateral knee OA patients, and aimed to seek different ground reaction forces according to pain (most painful knee-MPK and least painful knee-LPK) during stair ascending (STA) and descending (STD).

Methods: A cohort of 89 patients with knee OA was initially selected by family physicians, x-rayed, and observed clinically by a rheumatologist who selected 57 according to eligibility criteria (grade 2 or 3 knee OA (4)). Pain was assessed by the WOMAC VAS 3.1 pain dimension. Data was collected with the Novel Pedar-m® insole system when ascending and descending a flight of 12 steps (17cm height, 10:15 - 11:45
31cm deep), as fast as possible alternating legs in each step and without the use of handrail. Subjects were weighed with the system for posterior data normalization, and assessed with the same type of shoes to limit influence of different shock-absorbing properties. Results: Average pain level was 231.42 ± 103.28 (WOMAC pain sub-score), peak vertical ground reaction force (V-GRF) in Newton (N) was higher during STD than STA in both legs (MPK: 1030.5 ± 218.54, LPK: 1080.5 ± 245.55 vs MPK: 879.4 ± 205.97, LPK: 923.14 ± 197.19, p < 0.001). Maximum vertical impact in normalised units of body weight (IBW) was higher when STD than STA (MPK: 1.52 ± 0.26, LPK: 1.58 ± 0.32 vs MPK: 1.29 ± 0.26, LPK: 1.35 ± 0.22, p < 0.001). We also found differences between legs in the instant of peak vertical ground reaction force (% role over process (ROP)) during STD (MPK: 23.67 ± 16.26, LPK: 21.56 ± 9.86) and STA (MPK: 65.47 ± 14.25, LPK: 68.9 ± 13.98, p < 0.01).

Conclusion: Both in STA and STD maximum force (%I) and impact (IBW) were significantly higher in the least painful knee. We also found differences in-between legs in the instant of maximum force (%ROP). During stair descending %ROP was longer in the MPK once the LPK was used to slow down the transfer of weight. Contrarily in stair ascending subjects tend to transfer weight rapidly from the MPK to LPK. It seems that patients with knee OA, develop strategies during both stair ascending and descending to protect the most painful knee. In fact pain has been suggested to work as a protective mechanism that keeps patients from overloading the affected joint(s).

**ISOKINETIC EVALUATION FOR THE ACL RECONSTRUCTED PATIENT: DID WE FORGET STRENGTHENING EXERCISES FOR THE QUADRICEPS?**

Aydog, S., Horodyski, M., Moser, M., Indelicato, P.
Hacettepe University Department of Sports Medicine, Turkey; University of Florida, United States

Purpose.
Quadriiceps muscle weakness is common after ACL rupture and reconstruction. Quadriiceps strength and the hamstring/quadriceps (H/Q) ratio is often correlated to the anterior cruciate ligament (ACL) reconstructed patient’s functional status. Currently, one study has demonstrated that the H/Q ratio of 30° of knee flexion was strongly correlated to the functional score. We hypothesized that patients with ACL reconstruction would show a quadriceps strength deficit compared to the uninjured site and that strength measured at 30° degrees of knee extension and the first 1/3 work would be significantly lower than other strength measures.

Methods.
Using a cohort study design we reviewed the physical therapy strength records of 43 hamstring autograft reconstructed patients and 74 allograft reconstructed patients (patellar tendon, Achilles or tibialis anterior). The hamstring ACL reconstructions were applied by one orthopedic surgeon, and the allograft reconstructions were performed by another. The rehabilitation program was identical for both groups. Three, six, or twelve month isokinetic results (peak torque (PT), torque at 30º, torque at 0.18sec., total work, first 1/3 work, last 1/3 work) were reviewed for 117 consecutive patients who had received ACL reconstruction for unilateral primary ACL injuries at one institution between February 2006 to January 2007.

Results.
There are statistically significant differences between the hamstring and allograft groups at 6 months for time to operation, and at 3 months for age. Strength of quadriceps and side-to-side strength deficit was improved until 12 months, but strength of the hamstring didn’t improve after the 3rd month (p < 0.03). Side-to-side strength deficit for torque at 0.18 sec., torque at 30°, total work, first 1/3 work and last 1/3 work improved up to 12 months after reconstruction (p < 0.04).

Conclusion.
Side-to-side quadriceps deficit continues to improve until 12 months after reconstruction. These deficits not only occurred in the first 1/3 of knee flexion, but also through the full range of motion. It may be possible that if ACL reconstructed patients improve their quadriceps strength a little earlier in the rehabilitation program, they would have better functional status.

**EFFECT OF WHOLE BODY VIBRATION DURING DYNAMIC SQUATTING ON EMG ACTIVITY IN LOWER LIMB MUSCULATURE**

McCarthy, A., Donne, B.
Trinity College Dublin, Ireland

Whole body vibration (WBV) is used in training and rehabilitation regimes and studies have reported increased muscle activity during WBV (Bosco et al., 1999; Roelants et al., 2006). This study quantified and compared WBV induced EMG activity with unloaded and conventional mass loading during dynamic squatting.

Male volunteers (n=14) performed continuous dynamic squats (10 by 6s squat) on a WBV platform (Power Plate Ltd.) in unloaded, 20% body mass loaded and vibration loaded (2-5g) trials, squat rate and depth were controlled using a visual metronome. EMG activity via telemetry (ME6000, Mega Ltd., Finland) was recorded from vastus lateralis (VL), rectus femoris (RF), tibialis anterior (TA) and gastrocnemius (GM) using surface electrodes. Squatting action was videoed at 50Hz and a synchronised audio trigger facilitated analysis of concentric and eccentric actions during repeated cycles. Rectified EMG data (rmsEMG) were analysed for concentric (CON) and eccentric (ECC) actions to assess mean activity. Data were analysed using repeated measures ANOVA, post-hoc Tukey tests quantified differences and P<0.05 inferred statistical significance.

Analysis revealed significant increases in EMG activity when body mass was increased by 20% for RF (P<0.01) and VL (P<0.001) and for vibration loads 1g and 5g for RF, VL and GM compared to unloaded, however, no significant increases were observed in TA. For VL and RF, mean CON activity was significantly greater at 4g (VL: 289±23 vs. 409±42mV, P<43% and RF: 125±12 vs. 170±23mV, P<34%, P<0.01) and 5g (VL: 289±23 vs. 439±54mV, P<50% and RF: 125±12 vs. 184±25mV, P<46%, P<0.001) compared to unloaded. Mean ECC activity was significantly greater at 4g (VL: 424±48 vs. 548±65µV, P<30% and RF: 154±16 vs. 195±23µV, P<28%, P<0.05) and 5g (RF: 154±16 vs. 202±25µV, P<35%, P<0.01) compared to unloaded, and significantly lower than mass loaded at 2 and 3g (P<0.05) for RF. No significant differences (P>0.05) were observed during CON or ECC actions comparing mass and vibration loading at either 4 or 5g. Relative to unloaded trials, the mean increased EMG activity during CON mass loaded and 5g trials were comparable for RF (42% vs. 46%) and...
SPATIAL DIFFERENCES IN VENTILATION EFFICIENCY OF BICYCLE HELMETS.

Katholieke Universiteit Leuven, Belgium

Prevention of head injuries is highly influenced by the impact protection of bicycle helmets. Thermal discomfort was identified as a key factor for neglecting helmet use in the late 90’s. Therefore, manufacturers have shifted towards the production of helmets with more open structures. While open structures require materials with higher stiffness and thus lower damping, it can be questioned if they provide enhanced ventilation effectiveness.

In this research ventilation efficiency (cm³/cm³.s) of five bicycle helmets was quantified using a tracer gas measurement technique. Ventilation efficiencies were calculated for 13 positions between scull and helmet. Local ventilation efficiency allows quantifying fresh air distribution between head and helmet. Average ventilation effectiveness did not explain fresh air distribution between head and helmet. Variations in ventilation efficiency were significantly lower than either 4 or 5 g (P<0.05). In conclusion, the significant increases observed in EMG activity in RF, VL and GM during increased gravitational loads (4 to 5g) induced by WBV were comparable to 20% body mass loading. These observations suggest WBV as a possible alternative or complement to traditional resistance training.

References:
of the scull, while poorly ventilated zones were monitored at the back of the scull for all five helmets. An analytical model was introduced to estimate flow rate between head and helmet. Using this model, estimated flow rate was linearly correlated ($r^2 = 0.83$) with well ventilated areas under the five helmets that were studied. However, no correlation was seen between the estimated flow rate and poor ventilated scull area ($r^2 = 0.01$). Bicycle helmet design could be optimized using these results. Nevertheless, comfort levels should be introduced that allow physiological judging of ventilation effectiveness.

EVALUATION OF MURINE MODELS FOR EXERCISE TRAINING OF STRENGTH, MOTOR-COORDINATION AND ENDURANCE

Mooren, F., Wieber, S., Wilke, G., Hesselsmann, G., Tunca, E., Krüger, K.
Institute of Sports Sciences, Justus-Liebig-University, Giessen, Germany

Murine models are a suitable way in order to study molecular mechanisms of adaptations to exercise training. Most models focus on endurance training while other forms of training like resistance training and training of motor coordination are less well established. Purpose: To compare the specificity and interference of different approaches for training of strength, motor coordination and endurance in a mouse model.

Methods: Eight week old male C57BL/6 mice (n=8/group) were assigned to isometric strength training (STI), coordination training (CT), endurance training (ET) or control group (CO) for 10 weeks. Strength training was performed by hanging mice with their front and back paws on a vertical wire until falling down. For training of motor coordination a rotarod was used. The mice were placed on the rotating rod at increasing speed. Endurance training was performed by giving mice access to running wheels in their cages. Activity was monitored by a magnetic tachometer. All mice underwent exercise specific assessments of training status before, after 5 weeks and at the end of the training interventions.

Results: At the beginning the ST group was able to carry a weight of 40g for 2.57 ± 0.57min until falling down. This period increased significantly to 33.92 ± 7.17min after 10 weeks. Furthermore, strength training increased relative muscle weight of musculus biceps brachii, m. gastrocnemius/soleus and m. rectus femoris. CT group improved their coordinative skills from 34.37 ± 3.9 rpm significantly to 54.37 ± 6.34 rpm while ET group improved their maximum oxygen consumption (VO2max) from 59.0 ± 5.0 ml/min/kg to 72.9 ± 3.2 ml/min/kg. Adaptations of muscle weight were not observed in the ET and CT group. All mice improved their performance only in their specific types of exercise demonstrating no interference with the other components of physical fitness.

Conclusion: Ten weeks of different exercise training regimes resulted in specific functional and structural adaptations in mice. These approaches should be useful models to investigate the differential molecular and cellular effects of various training modes.

EXPERIMENTAL VALIDATION OF A TRAINING TO INCREASE THE SHOT SPEED IN WATER POLO

Hideki, T., Funasaki, H.
University of Tsukuba, Japan

The international rules in water polo have been widely changed in 2005 to make the water polo more attractive. One of key changes was that an allowed point for shot after an ordinary foul shortened from 7m to 5m away from the goal line. This change conducted not only an increase of goal-scoring opportunity but also a necessity of improving a shot speed further. For the shot speed in water polo, there were several references which analyzed relationships between the speed and kinematic/kinetic parameters during a shooting movement, however there were few studies which exercised a specific training for players, and validated an effect of the training. Therefore the purpose of this study was to exercise a specific training which can increase the shot speed and to evaluate effects of the training.

Eighteen Japanese male collegiate water polo players volunteered for the study. We divided the subjects into two groups that were a training group and a control group. Eleven players belong to the training group and they conducted special training programs which aimed to increase mainly muscle strength of upper limb and to improve an ability of eggbeater kick, for four months. We gave an individual weight training program aimed at strengthening of upper limb for each subject. In addition the training group conducted a special training with a tube which aimed for improving the strength and mobility of eggbeater kick during a shooting movement. Another seven players belong to the control group and they trained normally without any suggestions for the same period. Both groups have been training for two or three hours a day, six times a week constantly.

Before and after the training period we obtained data of anthropometric measurements, muscular strength measurement, kinematic parameters during shooting motion and an initial shot speed for both groups. By using upper and under water cameras, a whole body image during the shooting motion was videotaped and we obtained the kinematic parameters by three-dimensional analysis using the DLT method. The initial shot speed was measured by a radar gun (Bushnell SpeedStik) from a 8-meter mark away from the shooting point.

To evaluate the contribution of each parameter to a change of the shot speed, we obtained the Pearson’s correlation coefficient between variables. Moreover the multiple regression analysis was performed to determine the relationships between the morphological, muscular, kinematical factors and an improvement of shot speed.

As results, we found that both groups improved their shot speed. The training group significantly ($p=0.016$) increased by 3.3% while the control group did by 2.1% ($p=0.0008$). There were significant correlations between the shot speed and the following variables, muscular strength of wrist, a height of the right elbow and the right toe at the ball-release-moment in the training group. This result revealed that improvements of muscular strength of wrist and kinematic parameters altn

CONCURRENT VALIDITY OF A TRUNK TRI-AXIAL ACCELEROMETER SYSTEM FOR GAIT ANALYSIS IN OLDER ADULTS

Hartmann, A., Luzi, S., Murer, K., De Bruin, E.
Institute of Human Movement Sciences and Sport, ETH Zurich, Switzerland

Background: For clinical and research settings, objective measurements of spatio-temporal parameters of gait under real life conditions, e.g. in challenging environments, might help in identifying gait impairments and in evaluating effects of therapeutic interventions. A tri-axial accelerometer system placed on the lower trunk (DynaPort MINI Mod) has previously been identified as a valid measure for spatio-temporal gait parameters in children [1] and healthy, young adults [2,3]. Based on a more conservative gait pattern that is often observed in older adults it is not known, however, whether the accelerometer system can be applied in older populations. The purpose of this study, therefore, was to determine the concurrent validity of the DynaPort MINI Mod for gait analysis in older adults.
Results: The concurrent measures of gait velocity (ICC2,1 = 0.99, RC = 2.2%), cadence (ICC2,1 = 0.99, RC = 0.8%), step duration (ICC2,1 = 0.99, RC = 0.8%) and step length (ICC2,1 = 0.99, RC = 2.1%) were excellent. ICCs for variability measures of step duration and step length were respectively 0.52 and 0.20. The corresponding RCs were 85.1% and 88.0%.

Discussions: Our data indicate that the DynaPortMiniMod is a highly valid system for the analysis of spatio-temporal gait parameters in older adults. Because of the rather large RCs gait variability measures need to be viewed with caution. Future studies should investigate the sensitivity to change in various sub-populations undergoing training interventions.

COMPARISON OF HIDRODENSIOMETRY (HW), DUAL X-RAY ABSORPTIOMETRY AND AIR-DISPLACEMENT PLETHYSMOGRAPHY FOR ASSESSING BODY COMPOSITION OF OBESE ADOLESCENTS 15 TO 18 YEARS OF AGE: A PRELIMINARY STUDY

Colantonio, E., Dámaso, A., Salles, F., Inoue, D., Pinheiro, M., Szejnfeld, V., Mello, M., Tufik, S.
Federal University of São Paulo, Brazil

Comparison of Hidrosdensiometry (HW), Dual X-ray Absorptiometry (DXA) and Air-Displacement Plethysmography (ADP) for Assessing Body Composition of Obese Adolescents 15 to 18 Years of Age: a preliminary study

Emilson Colantonio; Ana R Dámaso; Fernando CA Salles; Daniela S Inoue; Marcelo M Pinheiro; Vera L Szejnfeld; Marco Túlio de Mello; Sergio Tufik.

Address: 1Center of the Studies in Psychology and Exercise, AFIP; 2Depart. of Psychobiology, Federal University of São Paulo; 3Depart. of Rheumatology, Federal University of São Paulo, São Paulo, SP, Brazil

Background: During the past decades, several new technologic developments have introduced alternative methods to determine percentage body fat (%BF). Allowing for a more accurate and precise assessment of body composition. Interest in assessing body composition in children and adolescent is rising, due in part to the increasing incidence of childhood and adolescence obesity. Purpose: to compare %BF determined by HW, DXA and ADP in a sample of obese adolescents. Methods: Thirty-six male and female subjects were recruited, including 15 males (16.00 ± 0.93 yrs, 105.05 ± 10.87 kg, 179.93 ± 7.18 cm, 34.91 ± 4.22 kg/m2) and 21 females (16.52 ± 1.50 yrs, 91.08 ± 10.48 kg, 163.57 ± 4.21 cm, 34.09 ± 3.64 kg/m2) who were tested using HW, DXA and ADP. The means of %BF observed by the three methods were compared by repeated measures ANOVA, and the intraclass correlation coefficient (ICC). Accuracy, precision, and bias were examined in DXA and ADP with HW serving as the gold standard method. Regression analysis was performed to determine the accuracy of DXA and ADP. Potential bias among DXA, ADP and HW were examined using Bland-Altman’s plots. Results: The means values and standard deviation of the three methods was: HW %BF total: 47.56 ± 7.79, boys: 46.22 ± 9.12, girls: 48.90 ± 6.47, DXA %BF total: 46.50 ± 4.61, boys: 42.34 ± 5.24, girls: 50.66 ± 3.98; ADP %BF total: 38.97 ± 6.22, boys: 35.60 ± 7.91, girls: 42.35 ± 5.33. Discussion/Conclusion: Comparison analysis among the %BF means of the three methods has shown that there was no significant difference.
between DXA and HW (p=0.300), whereas the mean of % BF by ADP was significantly lower than other two methods (p<0.001). The ICC for DXA versus HW and for ADP versus HW was 0.585 and 0.408, respectively. In fact, the ADP method tends to underestimate the % BF when compared to HW method. The DXA and HW methods seemed to be more closed than ADP, and to generate means values lower than another two methods. Considering the regressions using HW as accuracy criteria, the DXA was an accurate method and ADP wasn’t accurate method. Nevertheless, it is worth while to emphasize that the accuracy of DXA was not satisfactory, since the ICC value was low.

PS-3 Injury prevention & motivated intervention programmes

INJURY PREVENTION IN SPORTS

Langberg, H.
Institute of Sports Medicine, Denmark

Overuse injuries represents a major problem in sports. Worldwide more than 100 million musculoskeletal (tendon/muscle/bone) injuries occur annually. It is well established that skeletal muscle can adapt to changes in functional requirements and to increases in loading e.g. with exercise through muscle hypertrophy. Despite the ability of the muscle tissue to hypertrophy overuse occurs within the skeletal muscles during sports. Overuse injuries in skeletal muscles may be caused by overly intensive training and inadequate recovery, which subsequently leads to a breakdown in tissue rather than stimulating hypertrophy. In addition several studies on e.g. hamstring muscles have shown that it is possible to reduce the risk of sustaining a hamstring sprains by applying specific designed strengthening programs aiming at reducing the relative load applied to the muscles during sports activities. Along the same line specific training programs with focus on the neuromuscular component have been use successfully in the prevention of ligament injuries e.g. in the knee.

The hypertrophy of the muscles of cause increases the muscle power and thus the maximal forces and stress on the connective tissue within the muscle as well as on the tendons in series with the muscles fibres during contraction. This may lead to a situation where the forces exceed the strength of the connective tissue with the risk of injuries. In order to maintain this relationship and withstand the increased load tendons need to adapt to the new situation by increasing tissue strength either by hypertrophy, increased cross-links or increased tissue density. Data from recent studies indicates such a close relationship between cross-sectional areas of muscles and their tendons. Although tendons have been found to possess the ability to adapt to changes in load approximately 40% of the overload injuries within the musculoskeletal system are related to tendons and ligaments. As for muscle overuse injuries in the connective tissue may be defined as an imbalance between tissue strength and the load applied to the tissue, and prevention of overuse injuries in tendons should thus be possible through applying the correct load to the tendons. Unfortunately only few studies have been conducted on the prevention of overuse injuries within tendons. During rehabilitation however eccentric training have been found to be effective in reducing the pain and strengthening the tissue. Thus eccentric training may be a potential way of preventing overuse in the future.

Although overuse injuries represents a major and very costly problem within sports not much is know about the prevention of sports injuries. In addition athletes are constantly pushing the human body to the limits making prevention even more difficult, but hopefully our increasing understanding of who the human muscular skeletal system adapt will in the future provide more insight to how injuries should be prevented.

INJURY PREVENTION: FROM THEORY TO PRACTICE

Verhagen, E.
EMGO-Institute/VU University medical center, Netherlands

Safety in sports and physical activity is an important prerequisite for continuing participation in sports, as well as for maintenance of a healthy physically active lifestyle. For this reason, prevention, reduction, and control of sports injuries are important goals for clinicians, researchers, as well as for society as a whole. A crucial part of injury prevention in sports and physical activity is the understanding of injury risks and injury aetiology. In the early 1990’s several theoretical models have been put forward that have aided clinicians and researcher towards a better understanding of injury aetiology, and ultimately injury prevention. There is no doubt that the approach they encapsulate has led to a wide array of proven preventive measures for a variety of injuries within different sports. However, recently debate as arisen about the true effect of proven preventive measures in a real-life sports setting. Only research outcomes that will be adopted by athletes, coaches and sporting bodies will actually prevent injuries. The content of this recent debate is an important step forward for sports injury prevention. It implicitly describes the important role of behaviour in injury risk, and consequently injury prevention. Nevertheless, although recent ideas in sports medicine lead the way to a more behavioural approach of sports injury prevention, they remain unclear as to the role of behaviour in sports injury prevention. For this reason, a better understanding of the determinants of behaviour and behavioural change, and the relationship with injury risk is needed to successfully translate current and future knowledge in sports medicine to real-life injury prevention.
CELL-FREE PLASMA DNA RESPONSES FOLLOWING AN ACUTE BOUT OF CARDIOVASCULAR EXERCISE TO EXHAUSTION: EFFECTS OF SAMPLING TIME

Fatouros, I., Jamurtas, A., Nikolaidis, M., Michailidis, I., Douroudos, I., Chatzinikolaou, A., Destouni, A., Vrettou, C., Kanavakis, E., Papassotiriou, I., Taxildaris, K., Kourelas, D.
Democritus University of Thrace, Greece

Introduction
Circulating free plasma DNA (pDNA) is implicated in conditions associated with tissue injury, including apoptosis, exercise-induced inflammation, and athletic overtraining (1,2). Exhaustive exercise may lead to performance deterioration, various physiological maladaptations, acute breakdown and repair of skeletal muscle that can be described in terms of an acute inflammatory response (3). pDNA is altered both quantitatively and qualitatively in a variety of inflammatory conditions (tissue injury, cancer, and trauma) (4) and its concentration has been correlated with the severity of injury in trauma and training volume (1). In the present study we aimed to thoroughly investigate the time-course changes of pDNA and other inflammatory markers commonly used as indices of exercise-induced muscle damage by performing serial measurements during a 24-h period after an acute bout of strenuous cardiovascular exercise.

Methods
Eleven untrained men performed two trials. In the experimental trial, the subjects exercised for 45 min at 70% VO2max and then at 90% VO2max to exhaustion on a treadmill; in the control trial, the subjects remained at rest. Blood samples were drawn before and after exercise immediately post-exercise and at 0.5, 1, 2, 3, 4, 5, 6, 8, 10, and 24 h. pDNA, CRP, creatine kinase (CK), and uric acid (UA) were determined. Data were analysed by ANOVA repeated measures (p < 0.05).

Results
pDNA demonstrated its highest (p < 0.05) concentration immediately post-exercise (6141.4±251.8 vs. 171.4±34.6), remaining elevated (p < 0.05) for 30 min post-exercise (2697.2±212.4 vs. 250.4±39.1) and it was normalized thereafter. pDNA levels in the control group remained unaltered throughout the sampling period. CK and UA demonstrated a rise (p < 0.05) 30 min post-exercise and never returned to baseline. CRP exhibited a rise (p < 0.05) during the recovery period, peaking (p < 0.05) several hours following exercise (5-10 hours).

Discussion
Results of the present investigation demonstrate that pDNA is increased (15-fold) following an acute bout of exhausting cardiovascular exercise. pDNA rise preceded the up-regulation of other inflammatory markers such as CRP, CK, and UA. While pDNA was normalized shortly within recovery, the other inflammatory markers remained elevated. The etiology of this exercise-induced pDNA response is still unclear and warrants further investigation. The most suitable time point for collecting blood samples for pDNA measurement is immediately post-exercise and until 30 min within recovery.

INFLAMMATORY AND PERFORMANCE RESPONSES DURING A WRESTLING TOURNAMENT

Fatouros, I., Barbos, I., Rossoglou, C., Parotsidis, C., Jamurtas, A., Michailidis, I., Douroudos, I., Chatzinikolaou, A., Nikolaidis, M., Taxildaris, K.
Democritus University of Thrace, Greece

Introduction
Wrestling takes place in tournament settings requiring athletes to participate in multiple matches within a single day resulting in the development of additional stresses beyond those already created by weight loss alone (1). Strength/power of the upper and lower body’s musculature may be further compromised over the course of multiple matches of a wrestling tournament (1,2). This study investigated the inflammatory and performance responses of elite athletes during a Greco-Roman wrestling tournament.

Methods
Twelve male wrestlers (21.8±0.8 yrs; training age: 11.5±1.9 yrs) lost 5.8% of total body weight during the week before a single-day Greco-Roman wrestling tournament consisting of five games/wrestler (scheduled according to the Olympic tournament regulations). Performance (hand-grip and hip-back dynamometry, vertical jumping), muscle soreness (DOMS), assessment, and blood sampling was performed prior to and after each match while heart rate was monitored throughout each match and recovery. Blood samples were analyzed for lactate, glucose, leukocyte counts, creatine kinase (CK), C-reactive protein, protein carbonyls (PC), TBARS, reduced (GSH) and oxidized glutathione(GSSG) and total antioxidant capacity (TAC). Data were analyzed with repeated measures ANOVA (P<0.05).

Results
Blood lactate reached 17.21 mM (P<0.05) following each match and returned to baseline prior to the next match except from the fourth match. DOMS increased (P<0.05) following each match and returned to baseline before the next match except prior to the fourth match. Leg power and hip-back strength decreased (P<0.05) progressively during the recovery between the first four matches but they were restored before the fifth game. However, hand-grip strength demonstrated a marked (P<0.05) decline throughout the tournament. Leukocytosis was seen throughout the tournament, peaking (P<0.05) in the last match. CK and CRP increased (P<0.05) after each match and within recovery periods, peaking (P<0.05) prior to and following the last match. TBARS, PC, GSH/GSSG, and TAC analyses revealed a marked oxidative stress elevation (P<0.05) after each match which, in most cases, was not normalized prior to the next match.

Discussion
The results of the present study demonstrate that a single-day wrestling tournament induces a substantial inflammatory response which was even more pronounced prior to and following the last matches. Performance was deteriorated before the third and fourth match and in one case (hand-grip strength) it was never restored suggesting that upper body performance is more susceptible to deterioration than lower body performance. These data indicate that these athletes may not perform at their peak during the last matches of the tournament suggesting a need for more suitable programming and anti-inflammatory strategies within recovery.

IMMUNE SYSTEM IN ELITE COMBAT SPORTS ATHLETES
Matias, C., Silva, A., Monteiro, C., Raposo, M., Limão, F., Martins, F., Sardinha, L., Laires, M.
Instituto Nacional de Saúde Dr Ricardo Jorge, Portugal

Moderate exercise has been shown to improve immune defences whereas intense exercise seems to depress the immune system. The aim of this study was to evaluate the impact of an intense training season of combat sports (judo, karate and light) on the immune system of the athletes.

In this study participated 22 male athletes (AG) and 13 sedentary men (control group - CG) with ages between 18 and 31 years old. For the control group weight was 72.0±12.8 kg, height 1.78±0.06 m, body mass index (BMI) 22.6±3.37 kg.m-2, fat mass (FM) 14.1±6.30 kg and fat-free mass (FFM) 57.0±7.26 kg. For the athletes, the weight was 74.5±9.64 kg, height 1.74±0.05 m, BMI 24.4±2.54 kg.m-2, FM 8.76±2.78 kg and FFM 65.2±7.42 kg.

Blood and saliva were collected by standard procedures. Whole blood was used for lymphocyte subpopulations counting (CD4, CD8, CD3, CD19, CD16, total lymphocytes) by flow cytometry; serum for C reactive protein (CRP), high sensitivity C reactive protein (hsCRP), ceruloplasmin (Cp), haptoglobin (Hp), alfa1anti-tripsin (AAT), alfa1acid glicoprotein (AAG), properdin factor B (FPB), IgG, IgM and IgA by nephelometry; saliva for salivary cytokines (IL-2, IL-4, IL-6, IL-10, IFN-gamma, TNF-alfa) by Citometric Bead Array (CBA) and IgA (IgA saliva) by ELISA. Salivary IgA secretion rate was also calculated.

Athletes showed significantly lower Hp (CG: 92.8±39.1 mg.dL-1; AG: 50.7±44.5 mg.dL-1), higher serum IgA (CG: 178.1±55.5 mg.dL-1; AG: 240.0±88.9 mg.dL-1), and higher salivary TNF-alfa (CG: 9.32±2.90 mg.dL-1; AG: 12.4±5.45 mg.dL-1) than CG.

Athletes low Hp values are possibly associated with intravascular haemolysis due to physical injury, high serum IgA and salivary TNF-alfa levels can suggest the existence of chronic inflammation.

EFFECTS OF LOW AND HIGH GLYCEMIC INDEX CARBOHYDRATES ON PERFORMANCE AND BETA-ENDORPHIN LEVELS DURING EXERCISE
Tofas, T., Fatouros, I., Raptis, S., Yfantl, C., Paschalis, V., Nikolaidis, M., Koutedakis, Y., Jamurtas, A.
University of Thessaly, Greece

Endorphin (946E) is an opioid peptide representing the C-terminal 31 amino acid residue fragment of pro-opiomelanocortin (POMC). 946917 is released by the brain and has been shown to be affected by carbohydrate intake (Fatouros et al. 1995) and exercise (Goldfarb and Jamurtas 1997; Jamurtas et al. 2000). Low or High glycemic index is a measure of blood glucose changes following food intake and have been used in sports in order to enhance performance. However, it is not known what the effects are from the intake of different glycemic index foods on 946917 levels during exercise. Therefore, the purpose of this study was to examine the effects of low and high glycemic index foods on &A9;46;E levels during exercise. Eight young men volunteered to participate in this study. They underwent, in a randomized counterbalanced design, three experimental conditions. In the first one they received carbohydrates (1.5 gr per kg of body weight) of low glycemic index, in the second one high glycemic index (1.5 gr per kg of body weight) and in the third one placebo. Food was administered 30 minutes prior to exercise. Subjects cycled for 60 minutes at an intensity corresponding to 65% of VO2max which was increased to 90% of VO2max, until the subject could not maintain 60 pedalling revolutions per minute and the exercise time to exhaustion was recorded. Blood samples were drawn through a catheter prior to food consumption, 15 minutes prior to exercise, 0, 40, and 60 minutes into exercise, and at exhaustion. Blood was analyzed for beta-endorphin, glucose, insulin, and lactate. Data was analyzed using MANOVA repeated measures and the significance levels was set at p<0.05. The results showed that the mean time to exhaustion did not differ between the three conditions. There was a significant interaction in the glucose and insulin response (p<0.05) with the HGI exhibiting higher values at 15 and 60 time points. There was a significant increase of 946917 (p<0.05) at the end of exercise without however a significant interaction between the three conditions. Lactate, respiratory quotient, heart rate, VO2 and ventilation did not differ between the three conditions. These results indicate that consumption of either low or high glycemic index foods 30 minutes prior to exercise does not result in enhanced performance or if differences in -E levels.

IMMUNE CHANGES IN ELITE SWIMMERS OVER THE COURSE OF A TRAINING CYCLE
Morgado, J., Matias, C., Monteiro, C., Raposo, M., Alves, F., Seixas, T., Pessaio, P., Reis, J., Martins, F., Laires, M.
Faculty Human Kinetics, Portugal

The immune system (IS) reacts differentially to the chronic stress of exercise depending on several factors including intensity and duration of training, fitness level of the subjects and gender. Most of the findings about the influence of intensive prolonged exercise revealed an immunosuppression that can be associated, in some cases, to a overreaching state. Alternately, moderate exercise has been pinpointed as a potential enhancer of various parameters of the IS.

The impact of a 4 month training period of preparation for the swimming national championships on the systemic and mucosal immunity was assessed in a group of 13 elite Portuguese swimmers (7 female and 6 male) aged between 13 and 20 years old. The evaluation of the subjects was made in 3 different moments of the last macrocycle of the season (summer macrocycle): 1st preparatory, 2nd development and 3rd taper periods.
Blood and saliva restings were collected early in the morning at the 3 moments by standard procedures for posterior evaluation of leucocytes, total lymphocytes and CD3+, CD4+, CD8+, CD16+, CD19+ lymphocyte subpopulations by flow cytometry; serum immunoglobulin A (IgA) by Cytometric Bead Array (CBA) and salivary IgA (s-IgA) by ELISA. s-IgA (s-IgA) was calculated from s-IgA values. ANOVA for repeated measures with Bonferroni post-hoc test was used for the assessment of chronic exercise and gender effects. p < 0.05 was considered statistically significant in all cases. Mean values of the studied variables did not differ between genders and training effect was not gender dependent. Training induced a significant increase of total lymphocytes, CD3+ (Total T lymphocytes) and CD4+ (Th lymphocytes) and s-IgA from the 1st and the 2nd to the 3rd moments. CD8+ (Tc lymphocytes) rose from the 1st to the 3rd moment. CD16+ (natural killer NK) decreased from the 1st to the 2nd moment.

These findings show that the training process induced the stimulation of systemic and mucosal immunity restings values suggesting a chronic inflammation.

IS PREVENTIVE PHYSICAL EXERCISE IMPORTANT IN THE PROTECTION AGAINST CIGARETTE SMOKE-INDUCED PULMONARY OXIDATIVE RESPONSE?

Universidade do Extremo Sul Catarinense, Brazil

Reactive Oxygen Species (ROS) play an important role in the etiopathogenesis of pulmonary injury induced by exposure to cigarette smoke, and physical exercise may be useful with an impaired oxidative defense mechanism. However, the effect of preventive exercise on protection against cigarette smoke-induced pulmonary oxidative is partially known. Thus, the major aim of this study was to verify the preventive effects of physical exercise on cigarette smoke-induced pulmonary oxidative stress markers. Thirty six mice (C57 BL-6, 30-35g), were randomly divided in four groups (n = 9); control, cigarette, exercise, and cigarette plus exercise. The exercise groups were submitted to a program of physical training in water, five times a week, during eight weeks. The swimming sessions included two periods of 30 minutes each with a five-minute interval. The cigarette groups were submitted to passive exposure to cigarette smoke 15 times a day, four cigarettes per exposure, totaling 12 cigarettes per day, seven days a week for eight weeks. The animals were sacrificed by cervical traction 24 hours after the last exposure to cigarette smoke. Lung samples were isolated, processed, aliquoted and stored in 10% formalin at 40 °C. Initially, the lung sections were stained with hematoxylin-eosin, and hydroxyproline level was measured. Lipid peroxidation was determined by the quantity of thiobarbituric acid reactive species; protein carbonylation was obtained by determining carbonyl groups in a reaction with dinitrophenylhydrazine; catalase (CAT) activity was measured by the rate of decrease in hydrogen peroxide; and superoxide dismutase (SOD) activity was assayed by inhibition of adrenaline autoxidation. The differences among the groups were evaluated by one-way analyses of variance (one-way ANOVA); the results were expressed as means±SEM and the differences were considered different significantly with p<0.05. Pulmonary histological evaluation in mice treated with cigarette smoke demonstrated that physical exercise had a preventive effect on pulmonary parenchyma alterations and on hydroxyproline level. After exposure to cigarette smoke, a significant increase in superoxide was observed only in the cigarette group in relation to control. An increase in SOD activity was enough to reduce the oxidative damages observed in the same group. Moreover, no alterations in lipoperoxidation level and protein carbonylation were observed in the trained groups when compared to the control group, but results show a decrease of these markers in relation to the group exposed to cigarette smoke. These data suggest the preventive effect of physical exercise against the free radicals production in lung tissue. It is possible that the protecting response of exercise is related to the increased tissue resistance against oxidative damage and also to the improved antioxidant defense system.

INFLUENCE OF THE ADMINISTRATION OF ECSTASY AND OF THE ACUTE PHYSICAL EXERCISE IN THE HYDROGEN PEROXIDE PRODUCTION RATE ‘IN VIVO’ IN THE SKELETAL MUSCLE OF THE RAT

Ferreira, F., Ferreira, R., Carvalho, F., Duarte, J.
Faculty of Sport University of Porto, Portugal

This work aimed to analyse the influence of the administration of MDMA (10mg/kg ip) and of the practice of submaximum physical exercise (60 minutes, in a horizontal plan, 600m/h) in the hydrogen peroxide production rate in the mouse’s gastrocnemius muscle, and verify if the action of those two independent variables together increases the H2O2 muscle production rate. As indirect indicator of H2O2 production rate in vivo, the catalase residual activity (CRA) was quantified after previous administration of 3-amino-1,2,4-triazole (AT), an inhibitor of this enzyme in the presence of H2O2. Using this method, it was verified that the CRA time variations reflect, in an inverse way, the H2O2 tissue production rate. 30 mice, Charles River males, aged 12 to 14 weeks, with 42 ± 4.5g weigh, were used. The sample was aleatorily divided in 5 groups: AT control (CONT-AT, n=5), control (CONT, n=10), exercise (EX, n=5), administered with MDMA (MDMA, n=5) and administered with MDMA allied to physical exercise (MDMA+EX, n=5). The experimental protocol started (t0) with the AT administration ip (1g/kg) to the groups CONT, MDMA and MDMA+EX, and physiological saline to the group CONT-AT. 15 minutes later (t15), the animals were injected with MDMA (groups MDMA and MDMA+EX) or with physiological saline (groups CONT and EX). In the exercised animals, the physical exercise protocol happened immediately after the MDMA or the physiological saline administration. Every animal was sacrificed by cervical dislocation. The ones from the group CONT-AT were sacrificed 15 minutes after the physiological saline injection. All the other animals were sacrificed at 75 minutes (t75) after the AT administration. The group CONT, at 115 and 175, presented CRA values of 35.48 ± 2.73 and of 33.52 ± 4.14 U/mg protein respectively, significantly lower (p<0.05) compared to the group CONT-AT (44.13 ± 2.79 U/mg protein), which represents the base CRA value in t0. In the other groups, the CRA values at 175 were 21.76 ± 1.35 in group EX, 26.64 ± 2.30 in group MDMA and 21.30 ± 1.85 in group MDMA+EX. All of them revealed statistically more significant values (p<0.05) compared to intra-group CRA values in t15 and t0 (from group CONT-AT). The differences among the groups in t75 were significant (p<0.05) in the groups EX and MDMA+EX compared to group MDMA. These results prove the continuous H2O2 muscle production, even in base situations, and show that the practice of physical exercise or the MDMA administration, acting separately, increase the H2O2 production rate. The increase induced by physical exercise was more noticed. However, when the MDMA consumption was linked to the practice of physical exercise, the results were similar to the ones group EX achieved, which suggests that, on the contrary to what was expected, the association doesn't raise the H2O2 production rate in the skeletal muscle.
REDDENED ATROPHY GENE EXPRESSION IN MOUSE SKELETAL CELLS BY DEHYDROEPIANDROSTERONE SULPHATE

Duranti, G., Ceci, R., Sabatini, S.
IULM—University of Sport and Movement Sciences, Rome, Italy

Dehydroepiandrosterone sulphate (DHEAS) and its precursor dehydroepiandrosterone (DHEA) are multifunctional steroids produced by the adrenal gland. The production rate and levels of DHEA/DHEAS decrease gradually with advancing age suggesting an association between their decline and the general loss of skeletal muscle mass observed with aging. The most relevant factor, in muscle protein waste, is an enhanced protein breakdown associated with an increased expression of E3 ubiquitin ligases such as the muscle-specific ring finger protein (Murf1), which regulation is mediated by the transcription factor NF-κB (1). A DHEAS binding site has been identified in C2C12 myocytes and in human skeletal muscle (2) therefore we investigate if DHEAS may play a contrasting role in the process of muscle atrophy. Expression of Murf1, and myogenin, a muscle-specific transcription factor, were evaluated in response to DHEAS on mouse C2C12 differentiating muscle cells. We also studied the expression of thioredoxin (Trx), that represent one of the main endogenous redox-regulating molecules with thiol reducing activity. Trx has cytoprotective effects against oxidative stress and besides promotes DNA binding of NF-κB (3) whose activation is required for maximal atrophy. C2C12 myoblasts were grown in Dulbecco’s modified Eagle’s medium (DMEM) + 10% foetal bovine serum. At confluence of about 80% cells were shifted in 2% serum and at the same time treated with different concentrations of DHEAS. At the end of experiment total RNA were extracted, reverse transcribed and cDNA levels of Murf1, myogenin, thioredoxin and GAPDH were measured by semiquantitative PCR. A Western blot analysis were performed to determine myogenin levels.

Mylotubes treated with DHEAS concentrations from 1 M to 100 M showed that myogenin mRNA level was unaltered after DHEAS treatment. On the contrary myogenin protein was upregulated dose-dependently with the maximum at 100 M, suggesting that DHEAS may reduce the rates of muscle protein breakdown. In fact, a reduction of Murf1 and thioredoxin mRNA levels were observed with the maximal down-regulation, respect to control, also at 100 M DHEAS.

Our data suggest that DHEAS may act as an endogenous protective factor against muscle waste. DHEAS, through its inhibitory action on glucose -6-phosphate dehydrogenase (5), may reduce ROS generation from NADPH dependent pro-oxidant enzymes. The down-regulation of mRNA thioredoxin expression may lead to a reduction in NF-κB activation. Consequently DHEAS is able to stabilise myogenin, an important protein involved in muscle differentiation maintaining low levels of Murf1 expression.

EIGHT WEEKS RESISTANCE TRAINING LEADS TO MUCH OXIDATIVE STRESS PRODUCTION IN SEDENTARY THAN IN REGULAR EXERCISE STUDENTS

Wenpei, T., Chen, CL., Tsai, IS., Liu, YT.
National Changhua University of Education, Taiwan

Purpose: The aim of this study was compare the effect of 8-weeks resistance training on oxidative stress and antioxidant capacity between sedentary and regular exercise students. Methods: Seventeen college-age men (20.2 +/- 0.4 yr) were volunteered to participate in 8 weeks resistance training program. They included sedentary group from non-physical education students and regular exercise students from department of physical education. All subjects performed resistance training at 80% of one repetition maximum (1RM) for 8 weeks. The blood samples were taken before training and immediately (0h), 7, 24, 48, 72 hours after training. Results: (1) Sedentary group: The lactate dehydrogenase (LDH) activity were increased after 48 and 72h nitric oxide (NO) level were increased after 0-24h malondiadehyde (MDA) concentration was increased after 72h creatine kinase (CK) and uric acid (UA) concentration were increased after 24h and 48h protein carbonyls (PC) concentration was increased after 24h superoxide dismutase (SOD) activity was increased after 48 and 72h. (2) Regular exercise group: Creatine kinase (CK) activity was increased after 7h UA concentration was decreased after 0hPC concentration was increased after 24h NO level was increased after 24h and 48h TAC and CAT activity were increased after 0-24h; creatine kinase (CK) activity was increased after 48 and 10W; NO level was increased after 8W; TAC and CAT activity were increased after 10W and 12W (p<.05). Plasma malondiadehyde (MDA), protein carbonyls (PC) and superoxide dismutase (SOD) have no significant change for both groups during 0W-12W. Besides, the muscle strength after 8 weeks training was increased for both groups. Regular exercise group gained more muscle strength (252.8% vs. 225.3%) and reduced oxidative stress for both groups. Sedentary group produced much oxidative stress than regular exercise group. Meanwhile, this long-term resistance training was also increased antioxidant capacity; it increases more for sedentary group. Therefore, regular exercise can’t only increase muscle strength but also induce less oxidative damage.

CHANGES IN OXIDATIVE STRESS AND ANTIOXIDANT CAPACITY DURING TAPERING TRAINING

Wenpei, T., Chen, CL., Tsai, IS., Liu, YT., Huang, HC., Chen, TY.
National Changhua University of Education, Chung Shan Medical University, National Chung Hsing University, Taiwan

Purpose: The aim of this study is exploring the changes in oxidative stress and antioxidant capacity during tapering training before matches. Methods: Eighteen sedentary males (20.0 +/- 2.2 yr) were recruited to control group and tapering group. All subjects performed resistance training thrice a week at 80% of one repetition maximum (1RM). After completed training for 8 weeks, the control group stopped training and the tapering group keep training once a week for another four weeks. The blood samples were obtained before training (0W) and after training for 8, 10, 12 weeks. Results: (1) Control group: The lactate dehydrogenase (LDH) activity were increased after 8W and 10W, nitric oxide (NO) level was increased after 8W, urea (UA) concentration was decreased after 12W, total antioxidant capacity (TAC) were increased after 8W, 10W and 12W, catalase activity (CAT) was increased after 10W (p<.05). (2) Tapering group: creatine kinase (CK) activity was increased after 8W, LDH activity was increased after 8W, 10W and 12W, UA concentration was increased after 10W, NO level was increased after 8W, TAC and CAT activity were increased after 10W and 12W (p<.05). Plasma malondiadehyde (MDA), protein carbonyls (PC) and superoxide dismutase (SOD) have no significant change for both groups during 0W-12W. Besides, the muscle capacity (TAC) were increased after 8W, 10W and 12W; catalase activity (CAT) was increased after 10W (p<.05). (2) tapering group: creatine kinase (CK) activity was increased after 8W, LDH activity was increased after 8W, 10W and 12W, UA concentration was increased after 10W, NO level was increased after 8W, TAC and CAT activity were increased after 10W and 12W (p<.05). Plasma malondiadehyde (MDA), protein carbonyls (PC) and superoxide dismutase (SOD) have no significant change for both groups during 0W-12W. Besides, the muscle capacity (TAC) were increased after 8W, 10W and 12W; catalase activity (CAT) was increased after 10W (p<.05). (2) tapering group: creatine kinase (CK) activity was increased after 8W, LDH activity was increased after 8W, 10W and 12W, UA concentration was increased after 10W, NO level was increased after 8W, TAC and CAT activity were increased after 10W and 12W (p<.05). Plasma malondiadehyde (MDA), protein carbonyls (PC) and superoxide dismutase (SOD) have no significant change for both groups during 0W-12W. Besides, the muscle
strength after 10W and 12W training were significantly increased for both groups. Conclusion: Tapering training after 8 weeks increased much oxidative stress and muscle damage than stop training. Antioxidant capacities were increased for both groups. Because stop training increases muscle strength but not oxidative damage, it is better training model than tapering training before matches for athletes.

**MUSCLE DAMAGE INDUCED BY UPPER VS. LOWER BODY MUSCLE STRENGTH TRAINING EXERCISES**

Mota, M., Soares, J., João, V., Giesbrecht, C., Figueiredo, P.  
University of Trás-os-Montes e Alto Douro, Portugal

**Methods**  
Thirty subjects (average age = 20.9 ± 2.6 years) participated in this study. All subjects were previously evaluated in what concerns to maximal strength (1 maximal repetition) of upper body muscles (triceps, supine and lat pulldown) and lower body muscles (leg press, leg extension and leg curl). After one week, half of the subjects performed submaximal repetitions until exhaustion for upper body muscles and the other half performed submaximal repetitions until exhaustion for lower body muscles. One week later, the groups inverted the aim of the muscle strength training session. Capillary blood samples were collected before the each training session, 24 hours and 48 hours later for creatine kinase (CK) analyse in Refflotron Analyzer Plus. A comparison between blood CK values induced by upper body muscle training and by lower body muscle training was made through general linear model with repeated measures. Significance level was established at 5%.

**Results / Discussion**  
Our results revealed that blood CK values vary with the moment of evaluation, increasing significantly 24 hours later and remaining significantly high 48 hours later compared to the values obtained before each training session. Regarding the influence of upper or lower body muscle training on blood CK values, our results revealed that although higher values were obtained 24 and 48 hours later after lower body muscle training session, there was no significant difference compared to blood CK values after upper body muscle training session.

**Conclusion**  
Our results suggest that the recovery period between exercise training sessions for the upper or lower body muscle could be the same.

**AGE-RELATED LYMPHOCYTE MITOCHONDRIA RESPIRATION AND HYDROGEN PEROXIDE PRODUCTION IN TRAINED PEOPLE**

Mota, M., Peixoto, F.  
University of Trás-os-Montes e Alto Douro, Portugal

**Introduction**  
Mitochondria seem to be the most important subcellular site of hydrogen peroxide production in mammalian organs either by dismutation of peroxide ion on the electron-transfer chain of mitochondria or by the oxidative deamination of biogenic amines by monoamine oxidases on the outer mitochondrial membrane. It has been stated that generation of oxidants by mitochondria, and damage of mitochondrial components and functions by oxidants, are important aspects of the aging process. The aim of this study was to analyze the influence of exercise training on lymphocyte mitochondria function and hydrogen peroxide production with aging, in trained people.

**Methods**  
Ten men, aged between 27 and 52 years old (average age = 37.2 ± 8.8 years), engaged in regular physical activity participated in this study. Maximal aerobic capacity (VO2max. ml/kg/min) was assessed by spirometry until exhaustion, according to Bruce protocol. Human lymphocyte mitochondria oxidative activity with a Clark electrode (Hansatech Instruments) according to Miró et al. (1999) and mitochondria hydrogen peroxide production was assessed by fluorescence as described by Valletta and Berton (1987). A Spearman correlation was performed in order to test variables (age, mitochondria oxidative rate of Complex I and II and mitochondria hydrogen peroxide production) associations. Significance level was established at 5%.

**Results / Discussion**  
VO2max were 54.23 (± 4.68) ml/kg/min, mitochondrial oxidative rate was 12.7 ± 4.8 and 17.9 ± 7.9 nmol oxygen/min/mg lymphocyte protein for Complex I and Complex II, respectively, and mitochondria hydrogen peroxide production was 17.8 ± 2.2 µmol/ mg lymphocyte protein. Our results couldn’t find any significant correlation between mitochondria oxidative rates and age but mitochondria hydrogen peroxide production decreased significantly as age increased (r=-.709, p<.032).

**Conclusion**  
Our results suggest that regular exercise must be a stimulus for physiological mitochondrial biogenesis preventing and retarding the effects of aging process in mitochondria functionality decline. However, it’s possible that in larger samples and in older persons (close to 80 years old), where morphological changes in mitochondria cristae are more pronounced, age related mitochondria functionality decline should be visible, even between trained samples.

Blood and saliva samples were collected early in the morning by standard procedures before and after the performance of a 7 x 200 m crawl progressive test (protocol based on Pyne et al., 2001) for posterior evaluation of leukocytes, total lymphocytes and CD3+, CD4+, CD8+, CD16+, CD19+ lymphocyte subpopulations by flow cytometry; serum immunoglobulin A (IgA) by Citometric Bead Array (CBA) and salivary IgA s-IgA by ELISA. s-IgA secretory rate (sr-IgA) was calculated from s-IgA values. Blood post exercise values were corrected for plasma volume variation. ANOVA for repeated measures was used for the assessment of exercise and gender effects. Paired samples t-test was also used for comparisons between pre and post exercise values of each variable when exercise effect was gender dependent. p < 0.05 was considered statistically significant in all cases. The acute maximal exercise induced a significant increase of leukocytes, total lymphocytes, CD3+ (Total T lymphocytes), CD4+ (Th lymphocytes), CD16+ (Natural killer NK) and CD19+ (B cells), for the male group. Leukocytosis and an increased number of B cells after exercise were also observed for the female group. The concentrations of serum IgA, salivary IgA (s-IgA) and s-IgA secretory rate (sr-IgA) did not suffer any significant changes, in both genders. These findings show that the effect of a single bout of maximal exercise on immunity is gender dependent. We observed the stimulation of systemic immunity, which was more pronounced in males then in females, and the maintenance of the assessed mucosal immunity.

**SERUM CYTOKINES AND TOTAL ANTIOXIDANT CAPACITY IN MALE AND FEMALE ROWERS AFTER ACUTE EXERCISE**

Self, A., Gough, E., Syed, A., Knight, J., Armstrong, K., Castelli, L.
1-2University of Oxford, 3 Knight Scientific Ltd, Plymouth, United Kingdom

**Introduction**

The cytokine IL-6 (traditionally a pro-inflammatory cytokine but recently described as having anti-inflammatory effects) is proposed to mediate the beneficial effects of regular exercise in terms of systemic, low-grade inflammation (Petersen & Pedersen, 2005). An intensity-dependent increase in IL-1ra (anti-inflammatory) was observed in moderate exercise in women (Gough et al., 2007) suggesting that this cytokine may have more impact than IL-6 in these circumstances. Gough (2007) further suggested that total antioxidant capacity (TAC) may mediate IL-1ra release. The present study looked at the effects of repeated bouts of rowing on male and female rowers. Diet, lactates, total antioxidant capacity and three serum cytokines were compared on a gender basis.

**Methods**

Eight male (age 29yrs ±8.4; wt 81.3kg ±10.5; ht 1.85m ±0.08), 5 female (age 20yrs ±0.7; wt 62.2kg ±6.8; ht 1.70m ±0.05) healthy rowers participated in this ethically approved study. The exercise protocol consisted of a Concept II Rowing Ergometer step test. The serum cytokine concentration was measured with a monoclonal antibody sandwich ELISA kit (IL-1ra, R&D) and Immulite chemiluminescent assay (IL-6, IL-10). Serum TAC was quantified against an anti-oxidant standard in a chemiluminescent assay with peroxynitrite and the photoprotein Pholasin® (Knight Scientific). Statistical analysis used repeat measures ANOVA and paired t-test.

**Results**

IL-1ra was the only cytokine that increased significantly during the trial [P<0.01] and was significantly higher 1hr after exercise in women than men [P<0.05]. IL-10 was not detected. TAC also changed significantly with time [P<0.001]. There was no significant difference between TAC of men and women, although males tended to have slightly higher resting TAC scores, and females higher post-exercise scores.

**Discussion**

IL-6 did not increase in response to short duration exercise but IL-1ra did. These data lend support to the proposal by Gough et al. (2007) that IL-1ra may have more of an impact than IL-6 as an anti-inflammatory cytokine after this type of exercise. It is further proposed that there may be a significant difference between the inflammatory response of men and women to exercise which should be further investigated. The role of sex hormones and amenorrhoea would be relevant to such a study.

**AERODYNAMIC DRAG FORCE AND POWER WHEN CYCLING IN DIFFERENT METEOROLOGICAL CONDITIONS**

Marqués-Bruna, P., Grimshaw, P.
Edge Hill University, United Kingdom

**Introduction**

In the International Standard Atmosphere (ISA), at sea level with a normobaric pressure of 1,013.25 mb and 15°C temperature, dry air has a density of 1.225 kg/m3 (Massey, 1991). However, local fluctuations in barometric pressure, ambient temperature and relative humidity associated with prevailing weather conditions incur changes in the density of the air (Bertin, 2002), which determines the air resistance acting on the cyclist and the aerodynamic power required to overcome drag (Martin et al., 1998). This study aimed to model aerodynamic forces and powers in different meteorological conditions. The findings may be used by cyclists to sketch pacing strategies according to forecast weather.

**Methods**

This study used a hypothetical well-trained cyclist with a mass of 80 kg and a wind tunnel drag area of 0.261 m2 (Martin et al., 1998). The rider was assumed to be performing a 40-km time trial, unaccompanied, on an asphalted road and using an aerodynamic position on the bike. Wind direction was assumed tangential to the direction of cycling. Meteorological variations encompassed head and tail wind velocities of up to 5 m/s-1, sea level barometric pressures from 973.25 to 1033.25 mb, ambient temperatures of 0 to 40°C, and relative humidity levels of 10, 50 and 90%. Air density was computed as a function of weather parameters, and drag force was calculated using FD = 1/2rhCDAv2 (Massey, 1991). Bertin (2002) assuming a constant cycling velocity of 11 m/s-1. Aerodynamic power (absolute and as a percentage of total power) was predicted using the mathematical model of Martin et al. (1998), assuming a constant total power output of 255 W.

**Results**

328

13TH ANNUAL CONGRESS OF THE EUROPEAN COLLEGE OF SPORT SCIENCE
Drag force was less in high ambient temperatures; however, headwinds substantially increased absolute and relative aerodynamic power. Drag force and aerodynamic power were lowest (17.1 N and 191 W, respectively) in simulated weather systems that bring about low pressure (973.25 mb) and warm air (40°C), and highest (20.8 N and 233 W, respectively) when there was a combination of high pressure (1033.25 mb) and cold air (0°C). Dry (10%) and cold (0°C) air elicted more drag (20.4 N) and aerodynamic power (228 W) than humid (90%) and warm (40°C) conditions (17.4 N and 194 W, respectively).

Discussion/Conclusion

The mathematical model of Martin et al. (1998) allowed the prediction of air density and aerodynamic parameters (Massey, 1991; Bertin, 2002) associated with simulated weather conditions. Headwinds remain the worst enemy of the cyclist, particularly in combination with cold air. Weather systems characterized by low pressure, warm air and high humidity reduce drag force and aerodynamic power. Cyclist may consider a detailed assessment of forecast weather as an integral part of race strategy planning.

AERODYNAMIC EFFECTS OF ROAD TOPOGRAPHY AT THREE DIFFERENT LEVELS OF CYCLING PERFORMANCE

Marqués-Bruna, P., Grimshaw, P.
Edge Hill University, United Kingdom

Introduction

Aerodynamic drag acting on the cyclist is proportional to air density and the square of air velocity, which are respectively influenced by altitude and road gradient (Massey, 1991). Previous studies have modelled cycling performance as a function of individual environmental parameters (e.g., Martin et al., 1998; Atkinson et al., 2007). However, the aerodynamic effects associated with the interaction of topographical features have not been elucidated. Thus, this study aimed to model the individual and interactive aerodynamic effects of race course altitude and road gradient at three levels of cycling performance: recreational, well-trained and elite. The findings may be used by cyclists to select pacing strategies.

Methods

This study used a hypothetical cyclist with a wind tunnel drag area of 0.261 m² (Martin et al., 1998). The rider performed a 40-km time-trial unaccompanied, using an aerodynamic position on the bike. Cycling velocity and power output of the cyclist were adjusted to simulate three performance levels: recreational (9.33 m/s⁻¹, 164 W), well-trained (11.00 m/s⁻¹, 255 W) and elite (12.86 m/s⁻¹, 394 W) (Atkinson et al., 2007). Geometric altitude was modelled from sea level to 2500 m above sea level. Road gradient was simulated using alternating 2.5-km uphill (+2% gradient) and downhill (-2%) sections. Aerodynamic drag force and power (absolute and as a percentage of total power) were computed as a function of the individual terrain parameters. Finishing time was calculated based on the interactive effect of topographical features.

Results

Drag force and aerodynamic power dropped by 2.3 N and 30 W, respectively, per every 1000 m increase in altitude in the elite, by 1.7 N and 19 W in the well-trained and by 1.2 N and 12 W in the recreational cyclist. In uphill sections, air resistance accounted for 40, 48 and 55% of total power output in the recreational, well-trained and elite riders, respectively. The interaction of alternating ±2% road gradient and high altitude (2500 m) increased finishing time by 4 min and 15 s in the recreational cyclist, but saved 27 s in the well-trained rider and 2 min and 22 s in the elite cyclist.

Discussion/Conclusion

Cyclists should expect aerodynamic drag and power to decrease with altitude and relative aerodynamic power to decrease with both altitude and road gradient (Massey, 1991; Martin et al., 1998). As with individual environmental parameters (Atkinson et al., 2007), the interactive effects of road topography on cycling performance were closely related to the performance level of the cyclist. However, cycling performance may be predicted more accurately by modelling the interactive effect of topographical features.

STUDY REGARDING TORQUE MEASUREMENTS

Yamamoto, T., Mochizuki, K., Naguchi, K., Akita, K., Miura, K., Miura, M., Aoyama, H., Yoshihara, S., Katoh, Z., Tamura, M., Kita, T., Kyungok, Y.
MUSASHINO ART UNIVERSITY, Japan

Introduction

This research aims to evaluate two kinds of torques of the hip joint muscular power and the elbow joint muscular power measuring, and to do the comparative study between the two based on the measurements.

Methods

The factors were (1) distinction between hip-joint muscle strength and elbow-joint muscle strength, (2) distinction between inward and outward rotations, and (3) difference in gender. A total of 60 students, 30 male and female, were tested in the experiment. After comparing the data of test subjects, certain findings were obtained.

Discussion/Conclusion

A variance analysis of the measurement data gave the following results:

1. The torque value of men exceeded that of women. The difference was statistically significant at the 1% level. This is believed to reflect gender differences that we are commonly familiar with.
2. The torque value of hip-joint muscle strength showed a statistically significant excess over the torque value of elbow-joint muscle strength at the 5% level. It is generally known that legs have greater strength than arms, and the difference seen here between hip and elbow joints appears to follow a similar trend.
3. For both men and women, the torque value of hip-joint muscle strength during inward rotation showed a statistically significant excess over that during outward rotation.

MEASUREMENT OF THREE DIMENSIONAL ACCELERATIONS DURING THE PERFORMANCE OF THE SKI-JUMPING

Sasaki, T., Tsunoda, K.
Hokusei Gakuen University, Japan

Introduction: In ski jumping, the performance is divided in some phases that are the start, griding on inn-run, take off, flight and landing. In the flight phase, a jumper stays in the air for a couple of seconds after the take-off. If the whole of jump performance could be recorded exactly, each part of the performance can be analyzed more easily. It is interesting to know mechanical behavior in the series of the performance from take off to touching down phase. Especially, it is important to know how aerodynamic force affects the jumper and skis during the flight phase. The longer a jumper stays in the air, the longer flight length will be. So, a jumper cannot ignore the aerodynamic force at any occasion. Especially in the flight phase the gravity and the aerodynamic force affect a jumper. It is important to know the behavior of the accelerations for a jumper. We tried to prove our hypothesis about the influence of accelerations during jump performance by using a compact accelerometer with a gyroscope.

Methodology: This study was made possible with the collaboration of three voluntary jumpers during their training camp from 2006 Summer to 2008 winter. Jumpers jumped with a small accelerometer with a gyroscope. The accelerometer was set on the jumper’s back. The data was taken digitally with 200 Hz sampling frequency. The data were converted into global coordinate system by the rotational matrix known as Euler angles. The angle is obtained by the integrating the angular velocity from a gyroscope.

Results: Flight length was confirmed by one of their trainers. The mean of flight length was 93.5 m at the Hakuba. After the take-off, an aerodynamic force is calculated by subtracting the total force from the gravity. An aerodynamic force is divided into the drag force and the lift force on the body coordinate system. The range of fluctuation in the AC a is from the 0.15 to 0.5 m in all the three jumpers. In the period of the early flight phase, the total force vector is directed obliquely backward and downward on the trajectory. In the the middle of flight phase, the total force vector is directed obliquely downward and slightly forward that the lift forces are increasing. The drag force strongly affects a jumper than lift force during the early flight phase. Whereas the lift force become gradually larger than the drag force from the middle of the whole phase to the touching down phase.

Conclusions: The coordinate conversion technique in this study can obtain precise data in the flight phase. The data of flight phase is reliable to analyze the aerodynamic factors. During the early flight phase, the drag force strongly affects a jumper than lift force. The lift force become gradually larger than the drag force from the middle of the whole flight phase.

OPTIMIZED DESIGN OF A MOVEMENT ANALYSIS LABORATORY FOR RESEARCH IN SPORTS AND SPORTS EQUIPMENT

Janshen, L.
Humboldt-University Berlin, Germany

Introduction

Movement analysis plays an important role for both, enhancing athletes’ performance and clinical applications. In addition movement analysis is integrated in many fundamental and applied research and development processes, e.g. prosthetics, sport equipment or to improve the safety of car occupants.

Because of the high costs of a full equipped movement analysis laboratory, the efficiency in lab design and usage rate is important. This could be solved by a synergistic and interdisciplinary concept of a movement analysis laboratory. An optimized lab should provide most realistic conditions for a variety of sports, including individual and team sports as well as for clinical gait analysis and interdisciplinary motor control studies. In addition the lab should enable the testing of various sport equipment. The purpose of this paper is to present the technical requirements for an optimized movement analysis laboratory.

Methods:

A recently completed movement analysis laboratory will be used as an example to illustrate a model facility. Its concept and design is based on a requirement analysis. Current and future needs for research in sport science, physical education, medicine and for demands of sport associations and industrial partners have been considered. Special emphasis is given to the spatial design and to the technical construction requirements to integrate accurate measurement devices such as various force plates, marker based and markerless motion capture and wireless EMG. In addition important information for the planning process including a general timeline are presented. From these date, recommendations how to plan and build a movement analysis laboratory are derived.

Results:

The planning of the movement analysis lab has to combine the scientific purposes of use and all technical aspects of structural engineering, like building construction, electrical engineering, heating and air-conditioning. General aspects are room size, movement pathways, positioning options of force plates and camera systems in combination with the positioning of safety harness suspensions or housing technology installations. To provide most accurate measurements, the type of concrete used under the force plates and their separation during the flight phase. The longer a jumper stays in the air, the longer flight length will be. So, a jumper cannot ignore the aerodynamic force at any occasion. Especially in the flight phase the gravity and the aerodynamic force affect a jumper. It is important to know the behavior of the accelerations for a jumper. We tried to prove our hypothesis about the influence of accelerations during jump performance by using a compact accelerometer with a gyroscope.

Conclusions: The coordinate conversion technique in this study can obtain precise data in the flight phase. The data of flight phase is reliable to analyze the aerodynamic factors. During the early flight phase, the drag force strongly affects a jumper than lift force. The lift force become gradually larger than the drag force from the middle of the whole flight phase.

THE USE OF BIARTICULAR MUSCLES AFFECTS THE FORCE DEVELOPMENT

Ertelt, T., Blickhan, R.
Institute of Sportscience Friedrich-Schiller-University Jena, Germany

Biological systems can show a great variability with regard to the movement of its segments and for muscle control, which is based on a high number in degrees of freedom in joints and muscles. However, certain movement and activation patterns are still reliable (Bobbert and van Ingen Schenau, 1988). One example referring to the human jumping is the acceleration of the segments from proximal to distal. A similar behaviour can be observed for the description of the leg behavior. Here it appears that for certain frequencies one can see a
linear-elastic force-length relationship, which can be described by a simple spring-mass model (Blickhan, 1989, Farley et al., 1991). This applies for all people likewise. But it does not apply for hopping frequencies much lower than the preferred frequency anymore. The formerly observed force-length behavior is anything but linear-elastic, which is why the presumption suggests that this is caused by the longer contact times and greater joint movements during slow hopping.

To detect these changes in low frequencies, jumps were carried out on a sliding sledge (developed in Jenă). To carry out this specific experiment, the subjects were sitting below an inclined plane (inclination 20°). The subjects had the task to push a sledge (different weights) with different frequencies for 20 seconds. Beside the dynamographic data, also the kinematics and the activities of different leg muscles were registered.

The results show that the change of leg behaviour cannot be generalized. In spite of long contact times, great joint movements and high loads, some test persons were able to maintain the linear leg behaviour observed in high or preferred hopping frequency. This difference can be explained with an altered activation - and coordination pattern within sportspeople with jumping experience, which becomes visible due to their training. The other test persons show a multimode force pattern with plateau characteristics. This reason for the failure to maintain the linear elasticity can be seen in the different muscle activation. Particularly in biarticular muscle activation. Here the M. biceps femoris seems to have a key function. Jumpers use the force ability of the muscle to change the whole muscle coordination (Ertelt, 2008). This leads to an adequate movement, which supports a greater force generation. Through this, other structures (muscles, ligaments, tendons, bones etc.) can be preserved/disburdened or can make use of a higher muscle force on the same or a shorter way.

DIFFERENCES IN MAXIMAL SPRINTING SPEED KINEMATICS ON SLOPING SURFACES

Tomazin, K., Coh, M.
University of Ljubljana, Faculty of Sport, Slovenia

Sprinting up and down inclined surfaces are two of the most popular sprint training methods (Paradisis and Cook, 2006). One of the most important considerations of such training is the magnitude of changes in the kinematics of running. The aim of the study was to determine the differences in maximal sprinting speed kinematics on uphill and downhill slopes. Nine sprinters (20 ±3.5 y a., 74 ±2.7 kg, 179 ±6.8 cm) participated in this study. In order to assess differences in maximal sprinting speed kinematics, the 20 meter maximal sprint test was used. After a standardized warm up sprinters perform randomly 2 maximal sprints without inclination, 2 maximal sprints uphill and downhill, using a flying start. The slope inclination was 3.7°. Ten minutes recovery time was used between repetitions. Kinematic parameters were measured with Opto-track system (Microgate, Italy). Velocity, contact time, flight time, stride length and frequency of each stride were measured over running distance. Stride length and frequency were also normalised to body height. ANOVA for repeated measures was used to test the significance of differences in obtained parameters due to changes in inclination of running surface. In the event of significant main effect PostHoc Bonferroni was used to locate the differences. A repeated measures ANOVA showed significant main effect for maximum velocity (F(2,16)=26.6, p<0.001), absolute and relative stride length (F(2,16)=31.5, p<0.001), contact time (F(2,16)=10.7, p<0.01) and flight time (F(2,16)=5.8, p<0.05). Uphill running decreased maximum velocity compared to downhill (p<0.01) and horizontal running (p<0.01). Uphill running also decreased relative stride length compared to downhill (p<0.001) and horizontal running (p<0.001). Downhill and uphill running increased stride contact time compared to horizontal running (p<0.05). Results of our study showed that extra propulsive force during downhill running increased stride contact time although running velocity stayed the same. Thus could be due to greater distance between the centre of mass and the contact point compared to horizontal running (Paradisis and Cook, 2001). Uphill running decreased maximal velocity due to shorter stride length and increased contact time. Posture alteration during uphill running was probably not the main reason for contact time prolongation. An extra resistance load on the musculoskeletal and neural system during uphill running could be counteract only with great impulse (force x time) during contact phase, which could be seen during contact time prolongation. The results of our study implied that running on the different slope surface generate acute changes in the kinematic parameters due to different demands on the musculoskeletal and neural system.

ANALYSIS OF CRAWL FORCE AND FLOW FIELD USING A ROBOT ARM

Ozaki, T., Matsuuchi, K., Takagi, H., Nakashima, M.,
University of Tsukuba, Japan

Important factor which should be taken into account in swimming are the propulsive force. There were many studies about propulsive force in crawl, but in their studies it has been supposed that flow field around a swimmer is steady or quasi-steady. Schleihauf evaluated a force exerted on a hand in swimming using a quasi-steady analysis. However, swimmer’s motion cannot be evaluated quantitatively by the quasi-steady analysis, because of extremely unsteady characteristics. In general unsteady flow force is greater than the steady one. According to Toussaint et al., the quasi-steady analysis may give an underestimation of force. It is hence necessary to analyze the generating mechanism of propulsive force based on the unsteady flow. Top swimmers are expected to swim using effectively unsteady flow force. Our aim is to clarify the relation between the force exerted on an arm and flow fields around it. To detect these changes in low frequencies, jumps were carried out on a sliding sledge (developed in Jenă). To carry out this specific experiment, the subjects were sitting below an inclined plane (inclination 20°). The subjects had the task to push a sledge (different weights) with different frequencies for 20 seconds. Beside the dynamographic data, also the kinematics and the activities of different leg muscles were registered.

The results show that the change of leg behaviour cannot be generalized. In spite of long contact times, great joint movements and high loads, some test persons were able to maintain the linear leg behaviour observed in high or preferred hopping frequency. This difference can be explained with an altered activation - and coordination pattern within sportspeople with jumping experience, which becomes visible due to their training. The other test persons show a multimode force pattern with plateau characteristics. This reason for the failure to maintain the linear elasticity can be seen in the different muscle activation. Particularly in biarticular muscle activation. Here the M. biceps femoris seems to have a key function. Jumpers use the force ability of the muscle to change the whole muscle coordination (Ertelt, 2008). This leads to an adequate movement, which supports a greater force generation. Through this, other structures (muscles, ligaments, tendons, bones etc.) can be preserved/disburdened or can make use of a higher muscle force on the same or a shorter way.

cycle and the flow speed. We called three types stroke S, whose trace is like a figure S, stroke I, which is comparatively straight and stroke SI, which is the middle of stroke S and stroke I. We could evaluate the relation between the force exerted on a robot arm and the flow field around it. Since the forces and flow fields were measured simultaneously, we were able to investigate the mechanism of propulsive force.

The results show that the averaged thrust has almost same magnitude for all types of strokes from entry to exit. The maximum thrust was measured at the time when the arm changes the direction from in-sweep to out-sweep in the stroke S. At that time a vortex was observed to be released. It was found that the propulsive force was closely related to the generation and the release of vortices.

**RESULTS:** Ball velocity significantly decreased (P<0.05) after the implementation of the cutting maneuver task (Straight approach = 19.62 ± 1.89 m•sec-1 and Kick after cutting = 16.93 ± 1.41 m•sec-1). Similarly, the ball/foot speed ratio was significantly (P<0.05) higher during straight approach (1.59 ± 0.44) compared with the kick after cutting maneuver (1.52 ± 0.16). Kicking after cutting maneuver displayed lower velocity of the thigh (774.35 ± 79.31 vs 707.26 ± 81.69 deg/s), the shank (1625.62 ± 160.81 vs 1539.49 ± 194.38 deg/s) and the foot (1765.83 ± 162.38 vs 1571.02 ± 177.56 deg/s) compared with kicks after straight approach. Similarly, thigh, shank and foot angular velocity values at ball impact were significantly lower after cutting maneuver tasks (P<0.05).

**DISCUSSION:** The results of the present study indicated lower soccer kick kinematics when players performed kicks after cutting maneuver. This agrees with previous studies which reported decreased performance in running after cutting maneuvers (3). A powerful kick depends on proximal-to-distal sequence of segmental angular velocities (4) and transfer of energy between segments (5). This sequence agrees with previous studies which reported decreased performance in running after cutting maneuvers (3). A powerful kick is sustained by a higher velocity of the thigh, shank and foot. Therefore, a powerful kick after cutting maneuver tasks is less powerful compared with kicks after straight approach.

**STRATEGIES OF POSTURAL CONTROL IN STATIC AND IN DYNAMIC TESTING SITUATIONS**

Turbanski, S., Maier, R., Römhold, A., Schmidtbleicher, D.
University of Frankfurt/Main, Germany

**Introduction**

In order to gain a better understanding of postural control and to detect the individual risk of failing, one can evaluate subject's performance in specific balance tasks. Most often posturography is used to examine postural stability. At this subjects stand on a stable platform in static condition and motions of centre of pressure are analysed. Moreover, one can assess postural stability in balance tasks on an instable surface in dynamic condition. The aim of this study was to evaluate the relationship and differences between performances in postural control in static and in dynamic testing situations.

**Methods**

Twenty-three healthy male physical education students participated in this study (age: 24 +/-2.8 years, height: 182.0 +/-5.7 cm, weight: 78.7 +/-7.7 kg). Subjects were tested on their ability to maintain postural stability in a standardised one-leg stance (II) on a force platform (posturography, static condition) and (III) on a movable and instable platform attached to four springs (dynamic condition). We measured motions of centre of pressure (static condition) and displacements of support surface (dynamic condition). Furthermore, we recorded motions of the hip by an acceleration sensor attached to a belt. EMG-activity was recorded of the following muscles: m. tibialis anterior, m. gastrocnemius lateralis, m. vastus lateralis, m. biceps femoris, and m. erector spinae. Each measurement of postural control consisted of three tests on each leg (II and III) lasting 32 seconds. Trials were carried out in random order to prevent order effects.

**Comparison of postural control in static and in dynamic testing situations**

The correlation between postural control in static and dynamic testing situations led to poor correlations between performances in these two test situations (r=-0.11 L, r=-0.27 R). The motions of the hip increased significantly in dynamic testing situations (p<0.000 L; p=0.000 R). Moreover, EMG-activity (EMG) increased in all muscles in dynamic testing condition but reached the level of significance only in m. tibialis anterior, m. biceps femoris, and in m. vastus lateralis.

**Discussion**

This study reveals a surprisingly poor relationship between postural control in static and in dynamic testing condition. Regarding motions of the hip and analyses of EMG-activity we hypothesised different postural control strategies depending on testing situation (e.g. primarily hip-strategy versus primarily ankle-strategy). In conclusion our results suggest that measurement of postural stability in static conditions cannot predict performance in dynamic situations, e.g. to detect the individual risk of falling in elderly people and the risk of injuries in athletes.
RESEARCH ON TORQUE MEASUREMENT

Aoyama, H., Yamamoto, T., Mochizuki, K., Noguchi, K., Akita, K., Miura, K., Miura, M., Yoshihara, S., Katoh, Z., Tamura, M., Kita, T., Kinyungo, Y.

1Toyo University, 2 Musashino Art University, 3 St Marianna Medical College, 4 Mizuho University, 5 Meiji University, 6 Tokai University, 7 Ewha Womans University, Japan

Objective
The objective of the Study was to investigate how torque values of hip abductor and adductor strengths change over the course of a year, to compare MRI cross sections of the psoas major and erector spinae muscles, and to investigate their relationship to hip joint muscle strength.

Method
Evaluations of the psoas major and erector spinae muscles were based on cross sections obtained by Magnetic Resonance Imaging (MRI). Evaluations of hip abductor and adductor strengths were based on measurements taken with an exclusively developed hip-joint muscle strength measuring instrument.

Results
Part 1 Subject A: There was a positive correlation of 0.76 (significance level: 5%) between the abducence muscle (closed) and the right psoas major muscle. A positive correlation of 0.88 (significance level: 1%) was found between the adducence muscle (open) and the left erector spinae muscle. A positive correlation of 0.99 (significance level: 1%) was found between the left and right erector spinae muscles.

Part 2 Subject B: No statistically significant correlation was found between hip-joint muscle strength and the psoas major muscles. There was a positive correlation of 0.84 (significance level: 5%) between the right hip-joint muscle strength and the left erector spinae.

Part 3 Subject C: No statistically significant correlation was found between hip-joint muscle strength and the psoas major muscles. There was a positive correlation of 0.89 (significance level: 1%) between the left and right psoas major muscles.

Discussion /Conclusion
Only one of the three subjects showed a statistically significant correlation between hip-joint muscle strength and the psoas major muscles. No conclusion can be made concerning the existence or non-existence of any relationship between the two. Further studies are necessary to ascertain whether the small number of trials, lack of accuracy in attaining the central position for measurements, or individual differences had any bearing on the results.

Subject A: 40 years of baseball (underhand pitcher) Subject B: 45 years of golf

LOCALIZED MUSCLE FATIGUE EFFECTS ON LOWER LIMB KINEMATICS AND MUSCLE ACTIVITY DURING LEVEL RUNNING

Kelli, E., Liaou, C.

Aristotle University of Thessaloniki, Greece

The purpose of this study was to compare the changes in lower limb kinematics in running after a knee fatigue protocol with those observed after an ankle fatigue protocol. Sagittal kinematic data were collected from 15 female runners running at 3.61 m/s on a treadmill prior to and following an isokinetic knee extension / flexion (session 1) and an ankle plantarflexion / dorsiflexion (session 2) fatigue test at 120 degrees/s. Ankle muscle fatigue caused decreased dorsiflexion at initial contact while knee fatigue caused increased knee flexion at the same period (p < 0.05). Both protocols increased knee flexion angle at toe off while the hip was more extended after knee fatigue and the ankle more plantarflexed after ankle muscle fatigue. Ankle muscle fatigue caused a significant increase in hip extension and ankle plantarflexion angular velocity (p < 0.05). Knee muscle fatigue decreased hip and knee flexion velocity (p < 0.05). These results indicated that localized muscle fatigued effects on running kinematics differed between the two protocols. However, the strategy used to compensate for fatigue effects was similar for both protocols: to protect the joints at initial impact and to prevent impairments in performance during toe off and swing phase.

ALTERATIONS OF RUNNING PATTERNS DUE TO FATIGUE, COGNITIVE LOAD AND MAP OPERATING IN HIGH- AND LOW-LEVEL ORIENTEERS

Millet, G., Divert, C., Banizette, M., Morin, J.

Jean Monnet University, Saint-Etienne, France

Introduction. Orienteering is a good model to examine the interaction between cognitive tasks, biomechanical responses and fatigue. It can be hypothesized that elite orienteers have developed specific aptitudes to run at high velocity over prolonged periods of time while processing visual information on a map without injury. However, this hypothesis has never been tested. In this study, we examined the influence of fatigue on running biomechanics in normal running, normal running with a cognitive task and running while map operating, in orienteers of different levels of ability.

Methods. Nineteen international level and less experienced orienteers performed an exhaustive running exercise (~ 1 h at 70% VO2max) followed by a time to exhaustion (TTE) test at 85% VO2max and another 8 min at 70% VO2max on an instrumented treadmill to assess stride kinematics, kinetics and spring-mass model characteristics. At 8 min intervals during the 1h at 70% VO2max and at post-TTE, orienteering simulation (OS) (i.e. respond to as many orienteering questions as possible over 90-s sequences with a map in hands) or control running (CONTR) were requested. In order to differentiate the influence of the cognitive load from the influence of running while map operating, running patterns were also recorded during a cognitive task that did not modify the ‘natural’ run (mental arithmetic, MA).

Results. Kinematic and kinetic parameters were significantly different (P < 0.001) between both MA and CONTR compared with OS. However, no difference was observed between MA and CONTR. During CONTR, fatigue was associated with a lower (P < 0.01) maximal downward displacement of the center of mass during contact (delta-z) and an increased (P < 0.001) vertical stiffness (Kvert), while peak vertical ground reaction force (Fmax) did not change. A significant effect of the level of ability was observed for OS running (normalized by CONTR): a higher step frequency (+3.1%, P < 0.01), a lower Fmax (-3.9%, P < 0.05), a higher Kvert (+3.9%, P < 0.05) and a lower delta-z (-3.1%, P < 0.01).

STORIL / PORTUGAL, 09-12 JULY 2008
Twelve males and females performed three maximum isometric contractions (MVCs) of the knee extensors and flexors at 0°, 45°, and 90° knee joint angle and the level of muscle force. Information on muscle architecture related to joint positions is essential for the study of tendon and muscle properties of the hamstrings is important. Chleboun et al., (2001) found that the fascicle length and pennation angle of biceps femoris (BF) changed significantly as length changed. Due to the complexity of the hamstrings, its architecture and function are affected by the change of the knee joint angle and the level of muscle force. Information on muscle architecture related to joint positions is essential for the study of muscle function (Lieber,1993) and treatment of hamstring injuries. The purpose of the present study was to examine hamstring muscle thickness and aponeurosis stretch during ramp isometric contractions.

Method

Twelve males and females performed three maximum isometric contractions (MVCs) of the knee extensors and flexors at 0°, 45°, and 90° knee flexion angle. They then performed ramp isometric contractions of the knee flexors at 0%, 40%, 80% MVC. In each position, longitudinal ultrasonic images of the BF were obtained. The video images were digitized to measure aponeurosis strain and the muscle thickness during each position.

Results

The results indicated that for each knee flexion angle, as the MVC levels increased, the strain values increased. Particularly the strain values ranged from 3 to 10 cm, 6 to 13 cm and 5 to 14 cm at 0°, 45°, and 90° angles respectively. The muscle thickness decreased as the MVC level increased. The muscle thickness values ranged from 2 to 7 cm, 3 to 17 cm and 2 to 10 cm at 0°, 45°, and 90° angles respectively. The above results indicate that hamstring’s tendon elasticity increases as isometric force increases via a quasi-linear relationship.

This relationship could be used to model hamstring function muscle-tendon unit.

Hamstring thickness and stretch in isometric ramp contractions

Kouvelioti, V., Makrokis, M., Kellis, E.

Aristotle University of Thessaloniki, Serres, Greece

Hamstring muscle and tendon strains are frequent injuries in various sports. Therefore investigation of tendon and muscle properties of the hamstrings is important. Chleboun et al., [2001] found that the fascicle length and pennation angle of biceps femoris (BF) changed significantly as length changed. Due to the complexity of the hamstrings, its architecture and function are affected by the change of the knee joint angle and the level of muscle force. Information on muscle architecture related to joint positions is essential for the study of muscle function (Lieber,1993) and treatment of hamstring injuries. The purpose of the present study was to examine hamstring muscle thickness and aponeurosis stretch during ramp isometric contractions.

Method

Twelve males and females performed three maximum isometric contractions (MVCs) of the knee extensors and flexors at 0°, 45°, and 90° knee flexion angle. They then performed ramp isometric contractions of the knee flexors at 0%, 40%, 80% MVC. In each position, longitudinal ultrasonic images of the BF were obtained. The video images were digitized to measure aponeurosis strain and the muscle thickness during each position.

Results

The results indicated that for each knee flexion angle, as the MVC levels increased, the strain values increased. Particularly the strain values ranged from 3 to 10 cm, 6 to 13 cm and 5 to 14 cm at 0°, 45°, and 90° angles respectively. The muscle thickness decreased as the MVC level increased. The muscle thickness values ranged from 2 to 7 cm, 3 to 17 cm and 2 to 10 cm at 0°, 45°, and 90° angles respectively. The above results indicate that hamstring’s tendon elasticity increases as isometric force increases via a quasi-linear relationship.

This relationship could be used to model hamstring function muscle-tendon unit.

TRACKING AND ANALYSIS OF WHEELCHAIR RUGBY PLAYERS

Barros, R., Burkett, B., Malone, L., Misuta, M., Sarro, K., Sakalauskas, C., Russomanno, T.

State University of Campinas, Campinas, Brazil, University of the Sunshine Coast, Australia, Lakeshore Foundation, Department of Research and Education, Birmingham, AL, USA, Brazil

Wheelchair Rugby was introduced as a demonstration sport at the Atlanta 1996 Paralympic Games and became a full medal sport at the Sydney 2000 Paralympics. As with all elite sports the athlete and coach are seeking to better understand the sport-specific requirements of their sport and develop the framework for training and coaching. No previous study has provided kinematical data of wheelchair rugby players. The purpose of this study was to examine the kinematical data (distance traveled, velocity) of competitive wheelchair rugby players.

Method. The data were obtained with a tracking method based on computer vision techniques recently applied to characterize soccer player performance (Barros, et al., 2007; Figueroa, et al., 2006). The data acquisition used two Basler cameras fixed overhead on the ceiling, each one covering approximately a half court. The final match of the 2008 Demolition Derby in Birmingham, Alabama was analyzed. The positions of all eight players (n=8), four on each team, were determined simultaneously at 10 Hz for all four periods of the game. Prior to analyze the data were filtered with a Butterworth low-pass zero-phase digital filter with a cutoff frequency of 0.4 Hz, determined by spectral analysis. Results. The results were first examined using field diagrams showing the players’ motion during the match. From the curves of position in function of time, the total distance covered was calculated. In order to evaluate the possible effect of fatigue during the game, the distribution of distances covered in the first and second half for all players were compared. The data were tested for normality using a 2-sided goodness-of-fit Lilliefors test (p<0.05). After that, a one-sided paired t-test was performed to verify if the mean distances covered in the first half of the game were greater than in the second half. The total distance covered by the players ranged from 3522.3 to 5690.2 m (4563.3 ±822.8 m). Because the duration of first (31.6 min) and second (35.7 min) halves were not the same, the mean velocity value was compared. The mean velocity of player movement in the first half was 1.21 ± 0.20 m/s. The mean velocity of player movement in the second half was 1.06 ± 0.20 m/s. The results of the Lilliefors test (p<0.05) revealed that the data were normally distributed. The mean velocity in the 1st half of the game was significantly greater (p<0.001) than in the 2nd half, with a decrease of 13%. Conclusion. These results show the feasibility of this methodology to analyze wheelchair rugby. In addition, the results provide important information regarding player movement patterns during the game that can be used by coaches to plan adequate training strategies.

KNEE JOINT MOVEMENT DURING A SPORTS-RELATED TASK DESCRIBED BY THE QUATERNIONS METHOD

Cunha, S., Santiago, P., Cesar, G.

UNICAMP - State University of Campinas, Brazil

Introduction: Knee joint movement analysis during the single-leg drop landing task has been used in the study of sports-related anterior cruciate ligament (ACL) injury mechanism. Mathematical approaches have been utilized to describe joint rotational components during athletic movements, such as rotational matrices, Euler angles and quaternions. Among these methods, the least utilized in Biomechanics is the quaternions approach. Objective: The aim of the present study was to use the quaternions rotational representation to describe...
knee joint movement during the single-leg drop landing. Methods: Three collegiate female subjects without prior lower limb injuries participated in the study. They performed five single-leg drop landings from a 31cm platform, and the task was recorded with three 120 Hz digital video cameras. Six passive markers (three on the thigh and three on the shank) were utilized. Markers tridimensional raw data were obtained with the software Dvideow. Data Analysis: The software Matlab was used to smooth the raw data with the Loess function and to create segment coordinate systems of the thigh and shank to extract the unit quaternions from the knee joint observed in the task. Because it is an unit quaternion, its vectorial portion was converted from Cartesian coordinates to Spherical coordinates, and its scalar portion from radians to degrees. Results: The results obtained demonstrated that small alterations exist in the knee rotational axis (components of the unit quaternion during the airborne phase, with values of 3.9º±3.6º, 2.4º±1.8º and 1.2º±1º of longitude, latitude and rotation, respectively. After the initial foot contact with the floor an abrupt change was observed in the orientation of the knee rotational axis, characterized by the alteration in the three components of the quaternion, with 60.2º±23.1º, 44.5º±16.3º and 22.2º±4.6º of longitude, latitude and rotation, respectively. This sudden rotational axis alteration is considered one of the sports-related ACL injury mechanisms. However, there are no references about specific limits within the rotational axis that represent a risk factor for injury. Conclusion: The representation of rotational movements observed in human joints by means of the quaternions is an interesting alternative because it is possible to represent the joint rotational axis with fairly simple mathematical calculations when compared to other forms of representation. This is a relevant topic once movements are product of internal and external forces that result in rotations through axis (quaternions), which naturally occurs repeatedly in human joints. Therefore, it is suggested that the other forms of rotational representation should also be transformed to quaternions to allow comparison among studies, once the transformations are simple and provide a more adequate representation system to operate rotations without restrictions.

MUSCLE POWER OF LOWER EXTREMITIES IN RELATION TO BODY COMPOSITION OF TOP FEMALE RHYTHMIC GYMNASTS

Grande, I., Figueroa, J., Hontoria, M., Bautista, A., San Martín, M., Hervás, M.
University Alfonso X El Sabio 1, Real Federación Española de Gimnasia 2, Spain

It’s known that novice rhythmic gymnasts have a specific anthropometric profile that could be correlated with performance (2). Also other aspects like lean body mass and composite measures of flexibility, leg power and visuo-motor proficiency were also significant correlates of attainment (r = 0.69) (1). Due to the importance of anthropometric profile we evaluated Spanish senior national rhythmic gymnastics team during the preparation period before 2007 World Championship. The purpose of this study was to compare the anthropometric measurements and jump tests results during the season.

11 gymnasts from the Senior Spanish National Team participated for the study. The measurements were carried out at three different moments during the season. Muscle power of lower extremities was measured with a force plate (Kistler Quattro Jump) at 500 Hz. Gymnasts execute Squat Jump (SJ) and Counter Movement Jump (CMJ) tests. We selected the height (h), Peak Force (IN), Peak velocity (IN•s⁻¹) and Peak Power (W/Kg) of the highest jump execute at each test.

Anthropometric and jump capacity evaluation were made at the same week. Seventeen anthropometric dimensions were taken to calculate the anthropometric somatotype: stretch stature, body mass, nine skin folds, three bone breadths, and five limb girths. Statistical analysis was made with SPSS 15.0 software.

Significant correlation was showed between the thigh skin fold and SJ Peak Power (r = -0.41, p<0.05) and CMU Peak Power (r = -0.41, p<0.05). It was showed a significant correlation between thigh skin fold and SJ (r = -0.47, p<0.01) and CMU (r = -0.48, p<0.01) height. Low thigh skin fold data was revealed as indicator of better jump capacity.

We also found significant correlation between Endomorphic component with SJ (r = -0.44, p<0.05) and CMU height (r = -0.45, p<0.05). Endomorphic component also showed significant correlation with SJ Peak Power (r = -0.39, p<0.05) and CMU Peak Power (r = -0.43, p<0.05). Significant correlation was found between Percent body fat (Yuhasz) and SJ height (r = -0.41, p<0.05) and CMU height (r = -0.38, p<0.05).

An adequate decrease of endomorphic component, decrease of percent body fat, with a correlated increase of jump performance was showed during the preparation period of the world championship. These results revealed the importance of control the evolution of these variables during the training season of elite rhythmic gymnasts. It's necessary to check that the decrease of the endomorphic component is synchronized with the increase of the jump capacity.

SUB-MAXIMAL VELOCITY, TRAINING AND THE BEHAVIOUR OF BIOMECHANICAL PARAMETERS ASSOCIATED WITH RUNNING ECONOMY

Norte, R., Gabriel, R., Abrantes, J., Bulas-Cruz, J., Melo-Pinto, P., Filipe, V., Couto, P.
(IIS3 University of Trás-os-Montes and Alto Douro; II Technical University of Lisbon, Portugal)

The running economy has been associated to a variety of biomechanical variables (Saunders & col., 2004). The main goal of our study was to determine the differences between trained and untrained individuals, in relation to some of those biomechanical variables, during the support phase, in 3 different sub-maximal race speeds.

For the accomplishment of this study, 2 different groups were constituted with 8 adult males each, one of trained and another of untrained runners, to determine the behaviour differences of the variables (length and rate step, angles of ankle, knee and shank at the instants of initial contact, intermediate support and too-off, ground reaction forces in the antero-posterior and vertical components) with an increase of race speed (3, 4 and 5 m/s). For the cinematic data, 1 camera of high temporary resolution with a capture speed of 250 Hz was used along with the Sequen computer program (Gabriel & col., 1998) for the analysis of images. For the dynamic data, a Kistler 9281 B platform of forces was used and the results were analysed by the computer program Acknowledge 3.2.6 of BIOPAC Systems. To determine the behaviour differences, a t-test was used for matched samples (in non parametric sample distribution it was used the test of Wilcoxon). Then, the differences between the groups were tested using a t-test of 2 independent samples (Mann-Whitney test, in non parametric sample distribution), to determine the differences of behaviour accordingly the training level (p<0.05).

In the analysis between groups, a significant difference was verified in plantar flexion of ankle at to-off: t = -3.39 ±0.6º to untrained versus -20.3 ±15.2º to trained runners at 5 m/s speed race, p=0.04. In the kinetics data, just at 3 m/s, we verified a significant difference in
propulsive impulse (0.021 ± 0.005 BW.s to untrained versus 0.016 ± 0.007 BW.s to trained runners, p=0.02). With the increase of running velocity, the untrained increase the plantar flexion to obtain the same step length, while the trained runners probably increased the stiffness of the joints for a better use of the elastic properties of muscles, which seems better for running economy. In the reception, the trained runners have smaller impact impulse (0.036 ± 0.008 BW.s to untrained versus 0.030 ± 0.006 BW.s to trained runners, p=0.03 at 3 m/s and 0.038 ± 0.006 BW.s to untrained versus 0.032 ± 0.006 BW.s to trained runners, p=0.05 at 5 m/s), showing a better technical capacity to attenuate the impact impulse, with a smaller percentage of the impact duration in the total support time (13.3 ± 1.2% to untrained versus 11.9 ± 2.7% to trained runners, p=0.02 at 4 m/s). These characteristics seem an adaptation by training.

EFFECT OF THE CAFFEINE INGESTION ON THE NEUROMUSCULAR FATIGUE OF VASTUS LATERALIS MUSCLE DURING SUPRAMAXIMAL CYCLING EXERCISE
Moraes, A., Allimari, L., Fontes, E., Triano, R., Ezequiel, M., Okano, A., Balista, A., Dantas, J., Ribeiro, E., Coelho, N., Ramari, C.
State University of Campinas, Brazil

Research suggests that caffeine ingestion delays the development of muscular fatigue (Kalmar and Cafarelli, 2004). Thus, the purpose of the present study was to investigate the effect of the caffeine ingestion on the neuromuscular fatigue of Vastus Lateralis (VL) muscle during supramaximal cycling exercise. Eight male volunteers, amateur athletes of cycling (25.2 ± 3.1 yr, 70.7 ± 10.3 kg and 173.2 ± 6.0 cm) completed an incremental test (20W min^-1) until exhaustion to measure maximal power output (Wmax). Caffeine (CAF - 6 mg kg^-1) or maltodextrin (placebo, PLA) were administered in a randomized and double-blind procedure. One hour after ingestion, the subjects performed an exercise of constant intensity at 110% Wmax until volitional exhaustion. All tests were conducted in cycle ergometer (Computer-Trainer DYNAPL, RacerMate, Seattle, WA, USA) and separated by 72 h intervals. Cadence was allowed to range of 90 rpm. The test was terminated by the experimenter when the cadence dropped below 85 rpm. Before the start of testing, each subject had bipolar EMG electrodes (TSD 150, BIOPAC Systems Inc, USA) placed over the VL muscle of the right leg. The electrode was positioned following the standardization proposed by SENIAM (Hermens et al., 2000). Electromyographic (EMG) data were recorded during each cycling test (W50, BIOPAC Systems Inc, USA) in agreement with the ISEK (MERLETTI, 1999). EMG analysis was performed by calculating the root mean square (RMS-V) value every 10 s. During the supramaximal test, the time when fatigue started was obtained for the VL muscle - TVLFT. This was identified as the non-linear increase of the RMS values (breaking point). The participants were instructed to avoid all drinks containing caffeine during the experiment and a pilot study was used to familiarize the individuals with the equipment and procedures used. Normality of the data distribution was confirmed using the Shapiro-Wilk test, and this was followed by Student t-tests with level of significance set at p<.05. The results of the study showed that the TVLFT was significantly higher on condition CAF compared to PL (83.3 ± 14.6 vs. 75.0 ± 15.9 s, p<.05, respectively). According to these results, it can be concluded that the ingestion of 6 mg kg^-1 of caffeine increases time to neuromuscular fatigue of VL muscle during supramaximal cycling exercise.

EMG ACTIVATION OF ABDOMINAL MUSCLES IN THE EXERCISE ABDOMINAL PERFORMED WITH EXTERNAL LOADS
Moraes, A., Fontes, E., Triano, R., Ezequiel, M., Okano, A., Balista, A., Allimari, L., Dantas, J., Smirnou, B., Tosini, C., Moura, M.
State University of Campinas, Brazil

Abdominal exercises have been used thoroughly as a form of physical training. The objective of this study was to analyze electromyographic signs of the Rectus Abdominis and Obliquus Externus muscles during the execution of the movements with the addition of external overload. 18 students (18 and 25 years) participated in the study. The exercise abdominal crunch was used. The time of execution of the movement was 4 seconds. Initially, the test was accomplished using the maximum load. The movements were accomplished with a load of 20% and 40% in relation to the test of maximum load. For the collection and processing of the electromyographic signs, the acquisition system and analysis of signs MP150 BIOPAC Systems were used. The sampling frequency was established in 2000 Hz. The low pass filter to 500 Hz and the high pass to 10 Hz. For each registration, the root mean square (RMS) was calculated. Medium frequency (MF) of the average of the first three (I) and of the last three repetitions (F) were also found. Shapiro-Wilk’s test (to verify the normality of the data) verified the differences of the normalized values of RMS and MF among the analyzed phases and among the beginning III and final FI repetitions. Wilcoxon test was performed to locate the possible discrepancies. The results are as follows: the average of the movements in the load of 20% was 94 repetitions and for 40% it was 35. We presented the normalized values (%) (RMS) and (MF) expressed in medium and semi-width interquartilica for the somatoria of the muscles of the abdomen in the concentric and eccentric phases. In the load of 20% RMS in the concentric phase, the results were 56.86 (±12.37) in the beginning and 83.37 (±21.29) in the load. In the concentric phase, the value was 52.58 (±13.38) in the beginning and 46.68 (±12.37) in the load. For the load of 40% RMS in the concentric phase was 76.98 (±12.20) in the beginning and 103.67 (±17.48) in the end. In the eccentric phase the value was 65.70 (±5.97) in the beginning and 71.09 (±9.88) in the end. The difference was found between the phases and among the phases. The normalized values (%) of MF was 97.55 (±5.04) in the beginning of the concentric phase and 82.59 (±3.19) in the beginning of the concentric phase. In the eccentric phase it was 119.71 (±10.13) in the beginning and 93.60 (±6.25) in the end. We found differences between I and F for the two loads, between 20 and 40% in the eccentric phase and between concentric and eccentric in the same load. Considering Abdominal Synergy the representative measure of the abdominal muscles, in general, we can conclude that the abdominal muscles were significantly repeated with 100% repetition. The values in RMS demonstrated the participation of the muscles in the accomplished movements, while MF demonstrated there to be muscular fatigue among the initial and final repetitions for loads 20% and 40%.
CHANGES OF MAXIMAL POWER OUTPUT AND MUSCLE TORQUE IN MALE VOLLEYBALL PLAYERS DURING THE COMPETITIVE SEASON

Busko, K.
Josef Pilsudski Academy of Physical Education, Poland

INTRODUCTION
In volleyball technical and tactical skills, anthropometrics characteristics and individual physical performance capacities are most important factors that contribute to the competitive success of a whole team. Training for physical fitness in volleyball takes place primarily during the preparatory training period of the season, when less emphasis is directed to training of starting drills.

The aim of the study was to follow the changes of maximal power output and maximal muscle torque in male volleyball players during training performed in the preparatory period and competitive season.

METHODS
The study was conducted on 6 volleyball players from first league, age 25.0±5.3 years, body height 195.2±7.2 cm and body mass 91.2±14.7 kg. Force-velocity and power-velocity relations were determined from 5 maximal cycle ergometer exercise bouts, 10 s each, at increasing external loads equal to 2.5, 5.0, 7.5, 10.0 and 12.5% of body weight. The bouts were separated by 2 min intermissions. Maximal power output were computed from power-velocity curves. Maximal torque of the elbow, shoulder, knee, hip and trunk flexors and extensors were measured under isometric conditions on a special stand. ANOVA procedures for repeated measures were employed to data processing with post-hoc LSD test.

RESULTS
The sum of muscle torque of right and left lower extremities increased insignificant between the preparatory period (I) and the first competitive season (II) but decreased insignificant during the second competitive season (III). The sum of muscle torque of right upper extremities increased (p<0.05) from 316.9±37.4 Nm (I) to 341.7±32.0 Nm (II) and it decreased (p<0.05) during the second competitive season (315.9±22.2 Nm). The sum of muscle torque of left upper extremities increased (p<0.05) from 300.9±35.6 Nm (I) to 328.6±44.5 Nm (III) and 331.8±43.2 Nm (III). The sum of muscle torque of the trunk increased significant, too. Significant increases occurred in the maximal power output from 12.80±0.79 W (I) to 13.11±0.94 W (II) and 13.44±0.62 W (kg-1) (III).

DISCUSSION
The volleyball players were classifying to athletes specializing in power events. Thus the training of volleyball players should developed of strength and power output. In this study training of volleyball players improved the muscle torque of the trunk, upper extremities and maximal power output but the muscle torque of the lower extremities changed insignificant. In conclusions, in volleyball players increases occurred in the maximal muscle torque of the right and left upper (significant), and lower (insignificant) extremities during the preparatory period and the first competitive season while decreases were observed during the second competitive season (with the exception of the left upper extremities). The maximal power output increased during the all competitive season.

SPRINT RUNNING MOVEMENTS OF TYSON GAY AND ASAFA POWELL IN THE 100-M RACE DURING THE 2007 IAAF WORLD CHAMPIONSHIPS IN ATHLETICS

Takamoto, M., Ito, A.
Osaka University of Health and Sport Sciences, Japan

In the present study, the running movements of Tyson Gay (9.85 seconds) and Asafa Powell (9.96 seconds) who finished first and third, respectively, in the 2007 IAAF World Championships in Athletics were analyzed. Two high-speed video cameras (Phantom v4, Vision Research Inc, USA) were placed at the spectator stands in order to capture (100 Hz) Tyson Gay and Asafa Powell at the 60-m mark. The direct linear transformation method (DLT) was used to calculate three-dimensional coordinates of 24 body landmarks.

For Gay and Powell, step frequency was 4.90 and 4.96 steps/s, respectively, and step length was 2.42 and 2.40 m, respectively. Recovery leg movements were analyzed in terms of high knee angle (maximum angle formed by the thigh and the vertical line) and minimum knee angle. According to Itô et al. (1998) sprint running velocity is not related to the high knee angle, but the faster the sprint running velocity, the greater the minimum knee angle. For Gay and Powell, the high knee angle was 65° and 70°, and the minimum knee angle was 41° and 38°, respectively, and these numbers were similar to the data obtained by Itô et al. (1998). The horizontal distance from the toe at the point of landing to the center of gravity for the two sprinters was 0.31 m, and this number is comparable to that for sprinters who run 100 meters in 11 seconds (Fukuda and Ito, 2004). Itô et al. (1998) reported that while fast sprinters exhibited fast hip extension and slow knee extension of support leg, the maximum ankle planter flexion velocity of support leg did not correlate to sprint running velocity. However, an interesting finding was seen with maximum knee extension velocity of support leg for Gay and Powell. During landing, the knee joint of both sprinters always remained bent, and during the later half of the support phase, the extension velocity had a negative value, and the results of the present study suggest that sprint running technique has entered a new era. The maximum hip extension velocity for Gay and Powell was 774 and 693 degrees/s, and the maximum ankle extension velocity 664 and 743 degrees/s, respectively, and these values were most comparable to the data obtained by Itô et al. (1998).

The present results suggested followings. Training guidance that attempts to increase sprint running velocity by reducing the deceleration associated with landing must be reevaluated because the landing distance for Gay and Powell is comparable to that of sprinters who run 100 m in 11 seconds. What is important here is that Gay and Powell continue to bend the knee of the support leg during the support phase, and training guidance that instructs sprinters to actively extend the knee and ankle joints of the support leg must be reevaluated.

THE INFLUENCE OF THE GRAVITY CORRECTION TECHNIQUE TO THE RESULTS OF AN ISOKINETIC EVALUATION

Gouvali, M., Tsiouri, A., Boudolos, K.
National and Kapodistrian University of Athens, Greece

Introduction: Isokinetic Dynamometry (I/D) is a useful method for muscle torque evaluation. Corrections in the gravity of the evaluated limb are required for the accuracy of the method. The estimation of gravity torque is conducted through techniques such as 1) CM, maximum torque and respective angle during a passive drop of the limb and extrapolation to all angles of the movement range, 2) C30, torque at 30 angle during a passive drop of the limb and extrapolation to all angles of the movement range and 3), CAN, indirect estimation through anthropometric characteristics. The purpose of the study was the co-estimation of gravity torque, using the above techniques, in knee extension (E) and flexion (F) and comparison of the correction values among techniques.
**EFFECT OF ARM SWING ON RUNNING LONG JUMP PERFORMANCE**

Hara, M.
Japan Institute of Sports Sciences, Japan

Long jump involves a running approach until a take-off point after which a jump is made so as to achieve the maximum displacement of the centre of mass (CM). At take-off, one leg serves as the pivot for the jump. Previous studies on vertical and standing broad jumps report that arm swing affects lower extremities’ mechanical output and jump performance (Ashby et al., 2006; Hara et al., 2006). It may also significantly affect running long jump performance. This study quantifies and compares how the arm swing affects the biomechanical parameters at take-off during a running long jump, and understands the mechanisms that help arm swing lead to better long jump performance.

Five subjects (176.9 ± 11.5 cm, 72.6 ± 8.3 kg, 21.3 ± 2.8 years) executed long jumps with a short running approach. The jumps were made in two take-off conditions: with arm swing (LJA) and without arm swing (LJNA). The subjects ran on a runway and took off from a force platform. All performances were simultaneously captured with a 3-D motion capture system. From the obtained 3-D coordinates, the centre of joint was determined. Further, values of take-off CM velocity, radiation angle (take-off angle of CM relative to the transverse plane), jump displacement, and each joint variable were calculated. A one-sided paired t test compared the statistical differences between LJA and LJNA for each variable.

The CM displacements in LJA and LJNA were 4.38 ± 0.28 and 4.09 ± 0.34 m respectively. The jump performances were significantly better in LJA than in LJNA (p < 0.01). The radiation angles in LJA and LJNA, 25.7 ± 2.6 and 24.4 ± 2.0 deg respectively, and the CM velocities in LJA and LJNA were 6.28 ± 0.18 and 6.04 ± 0.27 m/s respectively. The radiation angle was significantly larger in LJA than in LJNA (p < 0.05). However, there was no difference between the take-off CM velocity in the two conditions.

A previous study on standing broad jumps reported that arm swing leads to improved jump performance because of increases in take-off CM velocity and lower extremities’ work output. However, in standing jumps, the radiation angle was not significantly larger with arm swing as compared to without arm swing (Hara et al., under submission). Given these, the results of this study suggest that in running long jumps, arm swing affects the increase in the radiation angle rather than that in the take-off CM velocity, thereby leading to an increase in horizontal displacement.

**RELATIONSHIP BETWEEN TIME TO PEAK TORQUE OF HAMSTRINGS AND SPRINT ACCELERATION IN MALE ATHLETES**

Bracic, M., Hadzic, V., Dervisevic, E., Coh, M.
University of Ljubljana, Slovenia

Muscle strength is thought to be a major factor in athletic sprint performance. Previous studies have investigated the role of hamstrings peak torque at high concentric velocities (240° and 300°/sec) finding significant positive correlations between two variables. However, no studies so far have investigated the relationship between time to peak torque (PTTof hamstrings and quadriceps) and sprint ability. A PTTo represents the time from the start of muscular contraction to the point of the highest torque development and is therefore a good indicator of the muscles functional ability to produce torque quickly.

36 healthy physical education students (age 19.69±1.36yrs, height 180.66±4.79cm, body mass 75.04±7.31kg) without previous injury participated in investigation. The measurements of the sprint acceleration phase were carried out in the Track and Field Centre. The infra-red photocell (Brower Timing System, USA) was used to time the performance. The subjects performed the 20m block-start sprint test 3 times, with 10min breaks between each effort. The best result was used in further analysis. Quadriceps and hamstrings strength was tested in the concentric mode of contraction at testing velocities 60, 180 and 240°/sec using Biodex System 3 dynamometer (Biodex Medical System, USA). The range of motion was set from 90° to 30° flexion. The main outcome measure for this study was peak torque (PTTo) and TPT of the knee extensors and flexors at 240°/sec. PTTo was adjusted for body weight and represented as peak torque to body weight (PTTo/BW). Multiple linear regression was used to evaluate the influence of predictors (PTTo/BW and TPT of quadriceps and hamstrings) on sprint times of 5, 10 and 20 meters.

The regression analysis has revealed that PTTo of hamstrings and quadriceps can predict the sprint times at 5, 10 and 20 meters. At all instances the linear regression model was statistically significant (F>7.11, p<0.01; F=5.31, p<0.01; F=4.10, p<0.01 for sprint times at 5, 10 and 20 meters, respectively) and R square values were 0.31, 0.26, and 0.21 for sprint times 5, 10 and 20 meters, respectively. The statistically significant predictor of sprint times was flexors TPT at 240°/sec (p values were 0.002, 0.05 and 0.02 for sprint times at 5, 10 and 20 meters, respectively). We must also mention that this parameter was statistically significant on univariate level as well (p<0.01 for all sprint times). TPT of quadriceps was not statistically significant predictor of sprint times.

The ability of hamstrings to produce torque quickly can significantly influence the sprint times at 20m sprint. The most of this effect is seen in the acceleration phase (first 5m) while later on (at 10 and 20m) this influence slightly decreases but remains significant. It seems that not only the absolute amount of strength, but also the rate of strength development within the muscle can influence the sprint times. We
can further argue that fast twitch fiber are those responsible for this fast torque production, and it is well known that these fibers play an important role in sprinters.

ESTIMATION OF THE SWIMMING PROPELLING ABILITY (PILOT STUDY)
Karsai, I., Silva, A., Garrido, N., Louro, H., Magyar, F., Ángyán, L., Alves, F.
1University of Péc, 2UTAD Vila Real, Portugal, 3 Research Center For Sports Sciences, Portugal, 4 Sport Sciences School of Rio Maior, 5 Faculty of Human Movement, Lisbon, Hungary

The amount of propelling force which moves the swimmer's body in the right swimming direction is the optimised interaction between the swimmer's hand-arm complex and the water, but the real way of the energy exchange is still unknown because of unsteady effects. Several model and analytical experiment provided considerable contribution to the explanation of the mechanism, but for the practical application the methods do not serve meaningful information. Direct force measurement is impossible during swimming and the Quasi steady method failed to be a useful tool. In this context, the purpose of this study was to investigate the relationship between the measured force data during tethered swimming and the force computed based on the kinematic parameters to obtain an insight about the swimmers propelling ability. We expect systematic changes across the parameters increasing the stroking frequency. An international level adult female swimmer participated in the study. Crawl arm stroke was performed from 25 to 55 c/m, the legs were tied and supported, 3 whole arm cycles were used for the analysis. Force production was calculated using a simple three segment model based on the kinematic parameters. Newtonian equation was used to calculate force production during the arm stroke and its projection to the swimming direction was compared with the measured force data, regression analysis was performed to test the expectation. The obtained results for force data were in accordance with the literature. The lowest mean value at 25 c/m was 32.64 N and the maximal 112.81 N. Increasing the frequency the mean and the maximal achieved force increases till the 30 c/m where the mean force rises up to 71.48 N and the maximal force 195.21 N. At the highest frequency step the mean force dropped considerably 63.03 N. Autocorrelation showed that the data were consistent during the experiments, highest R (0.923) value was observed at 40 c/m step. Regression analysis showed, that the performance can be described with a second order polynomial function: c=−75,551, b1=5,555 and b2=0.054, R Square: 0.951 considering the mean values. The ratio between measured and the computed values are at 25 c/m: 2.20 and reaches at 35 c/m the maximum 20.72 at 40 c/m: 16.59 and at the last two steps drops to 3.49. The shape of the function shoved an inverted U form the parameters of the second order function; c=−84,166 b1: 5,082 and b2=0.65, R Square: 0.714. By the results pointed out we can conclude that this method fits the requirements to express the magnitude of the unsteady effect caused by the swimmer’s hand arm complex. The combination of the kinematical parameters can give meaningful information from the structure of the performance. Further investigation is needed to reveal this function based on the gathered data and extend the experiment to higher number of participants.

NEW EVALUATION OF MUSCLE HARDNESS BY TAKING INTO ACCOUNT INDIVIDUAL MUSCLE THICKNESS
Murayama, M., Kuwada, K., Uchiyama, T., Yoneda, T.
Keio University, Japan

The evaluation of changes in muscle hardness is widely used for medical rehabilitation and conditioning in sports. Horikawa et al. (1993) provided the evaluation of muscle hardness based on a two-layered spring model by using a pressure devise non-invasively. An advantage of this model is that it can calculate two discrete hardness values of the subcutaneous and muscle components. However, it was not clear how much pressure should be applied on the body surface in order to evaluate muscle hardness. In fact, as the amount of distortion increase, the force-displacement relation will not be linear but exponential. If muscle hardness is calculated by the same amount of distortion, it will be overestimated in the case of an individual who has smaller muscle thickness. Therefore, in order to normalize the individual muscle hardness value, we attempt to compare the hardness values calculated from 5% to 30% muscle thickness. The purpose of the present study was to propose a relevant range of distortion for muscle hardness evaluation and the standard hardness value in the human elbow flexor muscles by taking into account individual muscle thickness.

A total of 157 college students volunteered to participate in this study. The thickness of the elbow flexor muscles (MT) and subcutaneous tissue (ST) were directly measured by ultrasonography. The muscle hardness meter, which was adjusted to the stage controller system, was used. The muscle hardness meter could be shuttled linearly for approximately 25 mm at 40 mm/sec by the stage controller system. During the muscle hardness measurement, the subjects remained in a sitting position with their back and arms positioned against a wall.

The mean value ± SD of the final depth of distortion was 49.7 ± 8.2 % and 54.8 ± 12.8 % of the MT in the male and female subjects, respectively. Consequently, it was suggested that the valid range of distortion was below 30% of the MT for the calculation of muscle hardness in the elbow flexor muscles of various individuals. Interestingly, there were no significant differences between male and female subjects in the each of the mean values of muscle hardness calculated from 5%, 10%, 15%, 20%, 25% and 30% MT. Therefore, a gender difference was not observed in muscle hardness. Although there were high correlations among muscle hardness values in 5% to 30% of the MT, it is possible that muscle hardness calculated from 10% or 15% MT is more adequate, because only these hardness values had no significant correlations with the ST. Furthermore, since 15% MT is a middle range for 30% MT, this area could represent the properties of hardness in both shallow and deep areas. In conclusion, muscle hardness should be calculated from an approximately 15% MT range.

As was described, the edge of the MT is a middle range for 30% MT, this area could represent the properties of hardness in both shallow and deep areas. In conclusion, muscle hardness should be calculated from an approximately 15% MT range.
THE RATIOS OF FLEXION/EXTENSION STRENGTH AFFECT BILATERAL DIFFERENCES IN THE JOINT TORQUES DURING SQUAT EXERCISES

Kobayashi, Y., Kubo, J., Matsubayashi, T., Matsuo, A., Kobayashi, K., Ishii, N.
The University of Tokyo, Japan

Introduction: Although we often assume that the kinetics in bilateral tasks such as squat exercises are almost symmetric, previous investigations show bilateral differences in vertical ground reaction forces (1) and the joint torques of lower limbs (2) during squat exercises. We hypothesized that these bilateral asymmetries were the results of the functional strength imbalance, such as greater right-left differences in maximal strength and/or larger ratios of flexion/extension strength.

Purpose: The purpose of this study was to investigate the relationship between the functional strength imbalance of lower limbs and bilateral differences in the joint torques during squat exercises.

Methods: Eight male subjects (age: 23 ± 1 yrs, height: 173.9 ± 7.3 cm, weight: 66.9 ± 6.0 kg) participated in this study. Before the experiment, isokinetic flexion and extension strength of the hip and knee joint were measured at 60 and 180 deg/sec, and the ratios of flexion/extension strength of each joint were calculated. Experimental protocol consisted of three sets of three repetitions of the squat exercise with the load of 50, 70, and 90% of 1 repetition maximum (1RM: 94 ± 17 kg). During the squatting movements, the positions of reflective markers attached to an anatomical landmarks of their body were recorded using three-dimensional motion capture system sampling at 120 Hz. Ground reaction forces were simultaneously recorded by two force platforms sampling at 1080 Hz. These data were processed to calculate the joint torques for the hip and knee joint. Pearson correlation analysis was used to evaluate the relationship among bilateral differences of each variable.

Results: In both knee and hip joint, there were no significant relationship between bilateral differences in isokinetic strength and bilateral differences in the joint torques during squat exercises. But bilateral differences in the ratios of knee flexion/extension strength at 60 deg/sec were significantly correlated with bilateral differences in the knee joint torque during squat exercises under any loading conditions (r = -0.764 ~ -0.782, p < 0.05).

Conclusion: These results suggest that the imbalance for the ratios of knee flexion/extension strength may affect bilateral asymmetries in the joint torques during squat exercises. Further studies are required to determine whether correcting the imbalance for the ratios of flexion/extension strength by strength training reduces bilateral differences in the joint torques during squat exercise.

THE ASSOCIATION BETWEEN SKELETAL MATURITY, SOCIO-ECONOMIC STATUS AND BODY MASS INDEX IN MADEIRAN CHILDREN AND ADOLESCENTS

Faculty of Kinesiology and Rehabilitation Sciences, K. U. Leuven, Belgium

The association between skeletal maturity, socio-economic status and body mass index was investigated in a mixed longitudinal sample of Portuguese children and adolescents (251 girls and 256 boys, 7 through 18 years of age).

Skeletal age was estimated from a radiograph of the left hand and wrist using the Tanner-Whitehouse method II. Socio-economic status was based on Census 91 developed by the Portuguese Institute of Statistics. Stature and body weight were measured and body mass index was used as an adiposity indicator.

Early maturing boys and girls showed higher body mass index values than their average and late maturing peers. The significant differences among maturity groups were not present in boys 14 to 15 years of age. Youngsters from families with a high socio-economic status showed a higher body mass index than those from families with an average or low socio-economic status. However, no significant differences were found between socio-economic categories for boys 10-11 years and for girls 12-14 and 15-18 years.

Body mass index is associated with skeletal maturity and socio-economic status in children and adolescents from Autonomous Region of Madeira, Portugal.
Results showed that the prevalence of physical inactive women was 55.6%, 52.3% had a BMI => 25 kg/m2, 18.5% were current smokers and 72.4% had an inadequate sleeping time. The risk behavior combination with higher prevalence was “physical inactivity, overweight) with physical inactivity.”

Conclusions: Among Azorean women, physical inactivity was not a predictor of the number of clustered risk behaviors, although having 1 overweight with physical inactivity.

FREE-RUNNING CIRCADIAN RHYTHM OF ISOMETRIC AND ISOKINETIC CONCENTRIC FORCE IN BLIND ATHLETES

Squarcini, C., Pires, M., Benedito-Silva, A., Cornelissen-Guillaume, G., Lopes, C., Matarazzó, C., Garcia, D., Peccin, S., Tufik, S., De Mello, M.

Federal University of Sao Paulo - UNIFESP, Brazil

Light is considered the main endogenous stimulus synchronizing circadian rhythms to 24 hours with the environment through body temperature, hormonal secretion and variables related to physical performance, particularly muscular strength. In light absence, as in the case of totally blind individuals, the circadian rhythms of body temperature and hormonal secretion tend to be free-run, with endogenous period of force and body temperature was statistically significantly longer than 24 hours, suggesting free-running of strength in totally blind athletes with free-running circadian rhythms. Data from participants six blind athletes with free-running rhythms for melatonin (or cortisol) secretion were collected for isometric force (handgrip and back flexion-extension), and isokinetic concentric knee flexion (at speeds 60º/s and 90º/s), and body temperature during three sessions at one- and two-week intervals. In each session, data were collected at 6 different times of day, with a minimum of 8-hour apart. Statistical analysis employed the cosinor method to determine each from initial acrophase (first session). Relative acrophases were pooled across all 6 subjects and linear regression as a function of days from start, the slope as a gauge of average daily shift. The results show that regardless of muscle group or contraction speed, the endogenous period of force and body temperature was statistically significantly longer than 24 hours, suggesting free-running of strength in
this athletes. Like as example: endogenous period (tau) of body temperature estimated as 24.8 hours, with 95% confidence limits of ±0.7 hour, for back strength tau = 24.7 hours (95%CI = ±0.8 hour) and for dominant extension of knee in 90°'s tau = 24.9 hours (95%CI = ±0.8 hour). It is concluded that the muscular strength rhythm is generated by an internal mechanism, since in absence of light perception the organism expresses a circadian rhythm. As far as we know, this is the first research to show the circadian rhythm of sports-related variable in blind individuals. Therefore, trainers and health professionals working with blind people should be aware of the importance of including a circadian rhythm evaluation in their routines.

ANALYSIS OF QUALITY OF LIFE AND HEALTH IN THE ADULT AGE: IMPLEMENTATION OF WHOQOL-BREF AND SF-36

Universidade Luterana do Brasil, Instituição Educacional São Judas Tadeu, UEX, Brazil

The quality of life is directly associated with the design of health, with both related to the different phases of life. With the increase in the aging population due to the increase in life expectancy, it is necessary to understand the interference factor of years of life in the daily routine of the population. The objective of the study was to analyze the relationship between quality of life and conception of health in people in three different phases: 30 to 44 years, 45 to 59 years and older than 60 years. Study participants were only women at the beginning of the programme with emphasis on the holding of regular physical activity in the Lutheran University of Brazil in Canoas, Brazil. The sample was composed, respectively, according to the age groups mentioned (mean +/ - average standard deviation), by 7 (41.71 years, 14 (52.71 +/- 4.12) e 11 (66.18 +/- 6.59) women. The instruments used were the Organization Quality of Life Assessment / WHOQOL-bref proposed by the WHO (Whool Group, 1998) and 'Short-Form Health Survey/SF-36'. It was used ANOVA and Pearson's correlation in the SPSS statistical program. The respective averages and standard deviation for each group on the components of the SF-36 were: emotional aspect 67.40 +/- 12.91; social support from family 75.57 +/- 13.26; self-efficacy 75.20 +/- 8.26; self-efficacy for physical activity 75.20 +/- 8.26; self-reported, generalized question measuring total physical activity.

Results: Based on multiple regression analyses conducted separately for boys and girls preliminary findings revealed significant relationships between the psychological, social and environmental factors hypothesized to mediate change in these behaviors has also been called for. The main objective of HEIA, a two-year multi-component school based intervention program, is to increase school children's physical activity, reduce sedentary behaviors (tv- and computer use) and improve specific eating behaviors.

Purpose: The present paper concerns the pre-intervention relationships between physical activity and factors hypothesized to mediate physical activity change. To this end we investigated associations of physical activity enjoyment, self-efficacy, social support from significant others and environmental opportunities for physical activity from friends and parents, hold school component x domain emotional and physical environment, social component x domain environment. Although the difference in age between the groups is statistically significant, the quality of life and conception of health presented no differences. Indeed, indicated the inter-relationship between some of its parts and areas, so more expressive in the group younger and older. Studies with similar themes need more attention!

CORRELATES OF CHILDREN'S PHYSICAL ACTIVITY: BASELINE RESULTS FROM HEIA, A TWO-YEAR MULTI-COMPONENT SCHOOL BASED INTERVENTION PROGRAM

Bergh, I., Grydeland, M., Bjélland, M., Lien, N., Klepp, K.L., Anderssen, S., Ommundsen, Y.

Norwegian School of Sport Sciences (1), Norwegian School of Sport Sciences (2), University of Oslo (3), Norway

Background: There is a need for innovative school-based intervention programs to promote healthy weight development in youth. With this in mind, influencing changes in physical activity, inactivity and eating behaviors seem important! Research on theoretically informed psychological, social and environmental factors hypothesized to mediate change in these behaviors has also been called for. The main objective of HEIA, a two-year multi-component school based intervention program, is to increase school children's physical activity, reduce sedentary behaviors (tv- and computer use) and improve specific eating behaviors.

Purpose: The present paper concerns the pre-intervention relationships between physical activity and factors hypothesized to mediate physical activity change. To this end we investigated associations of physical activity enjoyment, self-efficacy, social support from significant others and environmental opportunities for children's physical activity at baseline.

Methods: Children in 6th grade (11 year old) at 12 intervention schools and 25 control schools (N=1600) from the eastern part of Norway participated. As part of a comprehensive data collection at baseline (September 2007), pupils provided self-reported data for enjoyment, self-efficacy, social support by friends, parents and teachers and perceived environmental opportunities were collected together with a self-reported, generalized question measuring total physical activity.

Results: Based on multiple regression analyses conducted separately for boys and girls preliminary findings revealed significant relationships between the psychological, social and environmental factors and self-reported physical activity. Among boys the predictor set accounted for 30% of variance in physical activity, and 21% of the variance among girls. For boys, social support from friends (beta = .27, p<.001), social support from parents (beta = .12, p<.01), self-efficacy for physical activity (beta = .30, p<.001) were genuinely related to total physical activity. Among girls social support from friends (beta = .23, p<.001), social support from parents (beta = .12, p<.01), self-efficacy for physical activity (beta = .21, p<.001) and perceived environmental opportunities for physical activity (beta = .08, p=.05) were genuinely related to total physical activity.

Conclusion: Baseline results reveal that psychological and social factors amenable to change hold a stronger relationship to physical activity than environmental factors both among boys and girls. Future pre to post intervention analyses are needed in order to sort out whether these factors operate as mediating mechanisms in physical activity change. Current findings, however, suggest that influencing boys' and girls’ efficacy for physical activity as well as enhancing their social support for physical activity from friends and parents, hold promise as intervention target points.

LOYALTY IN PORTUGUESE HEALTH AND FITNESS CLUBS

Pedragosa, V., Correia, A., Barros, C.
Universidade Técnica de Lisboa - Faculdade de Motricidade Humana, Portugal

In this study, global satisfaction, measured in the long term, is evaluated in respect of three constructs (1-2): expectations (3), facilities (4) and loyalty (5). Expectations are considered as an innovative construct in their relationship with consumer satisfaction in health and fitness clubs. Facilities are measured in the short term in order to evaluate satisfaction by attributes, that is, all of the aspects encountered in using the various services provided by the HFCs. Loyalty is analysed by means of repeat purchases, recommendations to third parties and frequency of use. The sample comprises 463 respondents to a questionnaire, who are clients of two health & fitness clubs in the Greater Lisbon suburb of Oeiras, Portugal. The data was gathered by means of a questionnaire. Structural equation models were used. The model was analysed using a covariance matrix between the different variables manifested. The analysis was carried out with AMOS 7.0(6) statistical software. The results suggest that satisfaction is an intermediate variable, positively related with various other constructs and of crucial importance in determining the loyalty of health and fitness clubs. We concluded that global satisfaction takes on a role as intermediate variable with regard to the other constructs studied: expectations, facilities and loyalty. By taking expectations into consideration, we are able to conclude that their inclusion is essential in models studying their effect upon and relationship with satisfaction, which in the final analysis indirectly influences consumer loyalty through satisfaction. We also concluded that global satisfaction plays a vital role in consumer loyalty and that satisfaction with the facilities also indirectly affects consumer loyalty. Additionally, we complemented our conclusions by means of the verification that satisfaction with the facilities and global satisfaction, despite being two distinct concepts, are interconnected and are influential to consumer loyalty.

LOWER AND UPPER LIMB STRENGTH CORRELATE WITH AGE BUT NOT WITH BMI IN WOMEN AGED FROM 60 TO 83-YEARS

Furtado, H., Alves, J., Dantas, E., Reis, V.
University Castelo Branco, Rio de Janeiro, Brasil

The increasing ageing of modern populations drawn attention to the need to promote functional autonomy among the elderly, as independence and self-esteem seem to be dependent on the former. Aging promotes loss of strength, due to sarcopenia and osteopenia, which tend to lower the elderly functional autonomy. The aims of the study were to evaluate lower and upper limb strength in aged women from 60 to 83 years and to investigate possible correlations between those measures and body mass index (BMI). 125 women with mean age, weight, height and BMI of, respectively 67.79±5.60 years 64.68±11.39 Kg 1.54±5.11 m and 27.42±4.67 kg/m-2, performed the Chair-Stand (CS) and the Biceps Curl (BC) tests. These tests were used as described by Jones & Rikli, (2002). No correlation was found between the BMI and the CS and BC tests. However, we observed negative correlations between age and CS (-0.43) and between age and BC (-0.26) with statistical significance (P<0.00). The mean performance of the women in CS and BC were 10,95±3.87 times for CS and 13,42±3.47 times for BC. We concluded that the subjects that were evaluated did presented a deficit of lower and upper limbs strength. Moreover, these deficits increased with the age and were not influenced by the BMI. Therefore, engagement in physical activity programs was advised to the women that were evaluated.

METABOLIC SYNDROME AND PHYSICAL ACTIVITY IN ADOLESCENTS

Tammelin, T., Pirkola, J., Laitinen, J., Näsäkh, S., Ekelund, U., Remes, J., Ruokonen, A., Järvelin, MR.
Finnish Institute of Occupational Health, Finland

Purpose: Metabolic syndrome (MS) is defined by the clustering of central obesity, impaired glucose metabolism, dyslipidemia and hypertension and indicates increased risk of cardiovascular disease and diabetes. In adults, higher levels of moderate to vigorous intensity physical activity have been associated with a reduced risk of having MS, but there is little information regarding adolescents. This study aimed to evaluate the association between the level of physical activity and prevalence of MS in adolescents.

Methods: The study population consisted of 2565 males and 2638 females aged 16 years, members of population based Northern Finland Birth Cohort 1986 (NFBC 1986), who responded to a mailed questionnaire and were clinically examined in 2001-2002. Metabolic syndrome was defined using the International Diabetes Federation paediatric definition (Zimmet et al. 2007). Physical activity was assessed by self-report taking into account light, moderate and vigorous intensity activity after school hours and during transportation to and from school, and was summarised as metabolic equivalent hours (MET hours). Prevalence of MS and 95 % confidence intervals (CI) were estimated in the quintiles of physical activity described by MET hours.

Results: The overall prevalence of MS was 2.4%, and was higher in males (3.5 %) than in females (1.1%). In males, the prevalence of MS was inversely associated with the level of physical activity, and was 2.0% (CI 1.0 to 3.7) in the physically most active quintile and 4.7% (CI 3.1 to 7.4) in the least active quintile. In females, the prevalence of MS showed no significant variation by physical activity.

Conclusion: In males aged 16 years, the level of physical activity was inversely associated with the prevalence of MS while no such association was seen in females.

MUSCLE STRENGTH AND FUNCTIONAL PERFORMANCE IN ELDERLY MEN AND WOMEN

Prevc, P., Dolenec, A., Jereb, B., Rugelj, D., Tomazin, K., Ulaga, M., Palma, P., Strojnik, V.
University of Ljubljana, Slovenia

Elderly people show age-related decline in physical performance and decreased strength (sarcopenia) could be one of the important determinants of frailty. The purpose of this study was to assess the relationship between relative strength of leg and trunk muscles and different functional performance tasks. The aim was also to explore age and gender-related differences in measured abilities. Eighty-five nursing home residents, 30 men and 55 women aged between 60 and 94 years (79 ± 9), voluntarily participated in the study. The maximal strength of plantar and dorsiflexors, knee extensors and trunk extensors, flexors and lateral flexors was measured as isometric torque in the joint (the strength measures were adjusted for body weight). Performance measures were obtained by timing gait tasks in self-selected pace (6-m walk, ascending and descending stairs), Berg balance scale (comprised of 14 functional tasks) and maintaining static balance (20 second stance on the force platform with opened eyes and feet together). Pearson's correlation coefficient was used to determine the relationship between strength and functional performance and also for relationship between performance and ageing. Gender differences in strength and functional performances were measured with t-test.

All relative trunk and leg strength measures were significantly correlated with time to negotiate all three gait tasks (r=-0.27 to -0.52, p<0.05) and with total score of Berg balance scale (r=-0.33 to 0.59, p<0.005), while ability to maintain static balance didn’t show significant correlation with any of the relative strength measure. The only strength measures that showed a significant decline with age were trunk flexion (r=-0.31, p<0.005) and knee extension (r=-0.40, p=0.000), correlation with age was significant also in Berg balance scale (r=-0.32, p=0.003), maintaining static balance (r=0.24, p=0.03) and time to walk 6 meters (r=0.324, p=0.002). There were no significant gender differences in age or body weight. Men had compared to women significantly greater absolute and relative strength of all measured trunk and leg muscle groups (p<0.005). Men were faster in 6-m walking test and descending stairs (p<0.015) and had greater total score of Berg balance scale (p<0.05). But there were no gender differences in stair ascending speed and maintaining static balance. This study indicated that relative strength of the ankle, knee and trunk muscles showed important association with different functional performance measures, which all tend to decline with age. Men were relatively stronger and showed better functional performance than their women counterparts.

METABOLIC EXPENDITURE OF DEEP AND SHALLOW WATER RUNNING AT DIFFERENT STEP FREQUENCIES

Tiberi, M., Demarie, S., Dopretto, L., Faina, M.
University Institute for Movement Science - CONI Servizi S.p.A., Italy

Water running is a wide spread training method for enhancing strength and endurance without stressing impaired structure. Water running can be practiced in shallow water (WR), or in deep water (DWR). Work load can be modulated by varying movement frequency and range of motion. During water immersion, Heart Rate (HR) is reduced, if compared with land condition (1,2), for this reason it can not be a reliable parameter to calibrate work load. Therefore, aim of this study is to directly investigate various metabolic parameters during deep and shallow water running at different stride frequency (SF).

Nine female university students participated in the study. For WR subjects ran pushing against the bottom of the pool, at a water depth of 120 cm, for DWR they wore a specially designed buoyancy jacket and ran at a water depth of 180 cm. For both WR and DWR subjects ran for 4 min, at four progressive exercise intensities (at a frequency of 30, 40, 50 and 60 cycles min-1). Oxygen uptake, HR, ratings of perceived exertion (RPE) and blood lactate concentration were determined at each work load. Maximal oxygen uptake (VO2max) was determined on a treadmill.

Results demonstrated that between WR and DWR at the four SF there are no statistically significant differences in lactate accumulation, RER, energy cost, VO2 as percentage of VO2max and VO2 at the intensity estimated to produce 2 mM (aerobic threshold: AT) and 4 mM (anaerobic threshold: AnT) of lactate accumulation. HR, HR relative to estimated maximal HR and HR value relative to estimated maximal HR at AT and AnT. The HR values relative to estimated maximal HR at AT and AnT resulted of 70% and 82%, respectively, for WR and 66% and 77%, respectively, for DWR. A difference was instead found for RPE with significantly higher values during DWR at 40, 50 and 60 cycles min-1, but not at the lowest intensity of 30 cycles min-1.

The hydrodynamic resistance profile is different between DWR and SWR, therefore, it can be supposed that athletes less accustomed to DWR could be solicited to utilise their muscles in an unfamilier fashion. Additionally, the propulsive muscles of the lower limb (in particular Gastrocnemius and Soleus) are not heavily recruited in DWR due to the lack of ground reaction force (3). The higher exertion perceived by the subjects during DWR should be taken into account for rehabilitation purposes.

In conclusion, water running continuously for 60 minutes at 50 stride per minute, produces an energy expenditure of around 380 Kcal for the subjects during DWR should be taken into account for rehabilitation purposes.

THE FACTORIAL STRUCTURE OF THE GREEK SF-36 HEALTH SURVEY

Karteroliotis, K., Theodoropoulou, E.
Ethniki and Kapodistriako University of Athens, Greece

Background: The SF-36 Health Survey is the most widely used questionnaire for the assessment of quality of life. The 36 item survey assesses eight separate factors of quality of life: physical functioning, bodily pain, general health perceptions, vitality, social functioning, role disability due to emotional problems, and general health. The SF-36 was evaluated in samples from ten nations: Denmark, France, Germany, Italy, the Netherlands, Norway, Spain, Sweden, the United Kingdom, and the United States(1). A first-order confirmatory factor analysis (CFA) that hypothesizing 8 latent factors was found to describe the SF-36 data adequately for each nation. A hierarchical CFA model that hypothesized one third-order factor and three second-order factors (physical health, mental health, and general well-being) also demonstrated good fit to the data(2). The present study examined the multidimensional and hierarchical structure of the SF-36 in a Greek population.

Methods: Data were obtained from 327 healthy men and women residing in Athens. The Greek-language version of the SF-36 was used(3). The eight subscales were scored from 0 to 100. A CFA was employed to examine the factorial structure of the SF-36 questionnaire. The evaluation of the structure was made using the AMOS Version 6 computer program(4).
Results: Results suggested that the model with the eight first-order correlated factors provided a satisfactory fit to the data ($x^2(526) = 1019.23$, RMSEA = .054, NNFI = .87, and CFI = .89). However, higher order analyses showed that a model with two correlated second-order factors (physical health and general mental health) did not provide a satisfactory fit to the data ($x^2(552) = 1633.20$, RMSEA = .078, NNFI = .73, and CFI = .75). Finally, a third-order factor (health) model, including a third second-order factor (general well-being), represented a reasonable fit to the data ($x^2(526) = 1116.58$, RMSEA = .057, NNFI = .86, and CFI = .87).

Conclusions: Results of the study confirmed the multidimensional and hierarchical structure of the SF-36. Further research is needed with this questionnaire in order to determine the construct validity of its proposed hierarchical 8-factor structure.

2 Keller SD, Ware JE, Bentler PM, et al. Use of structural equation modeling to test the construct validity of the SF-36 Health Survey in ten countries. Results from the IQOLA Project. J Clin Epidemiol 1998; 51:1179-1188.
dependent and independent variables we used the Spearman correlation coefficient. The overweight and obesity prevalence in the studied sample was 38.8% in total, 48.8% in girls and 32.7% in boys. Significant results were found between the BMI comparison and the following variables: BMI in categories (p=0.000 for both sexes), age (p=0.000, for boys), spare time on physical activities (p=0.002, for boys). Only one association was found, between BMI and time spent at the computer (p=0.05, for 8 years old girls). The results suggest that the prevalence of children with overweight and obesity is high. Factors like gender, age, time spare in physical activity and watching television, have influence on the variation of the BMI values. To prevent obesity the sedentary lifestyle reduction and physical activities promotion are suggested.

DIFFERENCES IN CORONARY HEART DISEASE RISK FACTORS ACCORDING TO PHYSICAL ACTIVITY LEVEL IN YOUNG ADULTS

Kin-Islıer, A., Ozkan, A.
Baskent University, Turkey

The purpose of the present study was to determine differences in coronary heart disease risk factors according to physical activity level in young adults. A total of 188 volunteer university students (female: 98, male: 90) participated in this study. For the determination of coronary heart disease risk factors subjects’ body mass index (BMI), body fat percentage (Fat %), systolic (SBP) and diastolic (DBP) blood pressures, total cholesterol (TC), triglyceride (TG), low-density lipoprotein cholesterol (LDL-C) and high-density lipoprotein cholesterol levels were determined. Physical Activity Assessment Questionnaire (PAAQ) was used for the determination of physical activity levels and subjects were divided into two groups as highly active and moderately active based on the median values of the PAAQ (MET/week). Results indicated that for the whole group and for female and male university student separately significant differences were only observed in physical activity levels (total group: t=18.301, p= .000; females: t=12.519, p=.000; males: t=13.676, p=.000) however no significant differences were determined in BMI, Fat %, SBP, DBP, TC, TG, LDL-C and HDL-C. As a conclusion present results suggest that coronary heart disease risk factors were not affected by physical activity levels in young adults.

COMPARISON OF TWO ACCELEROMETERS FOR THE MEASUREMENT OF ENERGY EXPENDITURE IN FEMALES DURING WALKING

Harrington, D., Donnelly, A.
University of Limerick, Ireland

Objective and valid measures of Physical Activity (PA) are important for quantifying free living PA levels in different populations (Rowlands & Eston, 2007). One non-invasive method of estimating PA is collection of data from recording accelerometers, which allow several days of continuous measurement. Data from accelerometers can be used to estimate energy expenditure in activities such as walking. The aim of the study was to compare the effectiveness of two accelerometers, the ActivPAL Professional physical activitylogger (PAL Technologies Ltd, Glasgow, Scotland) and the Actigraph accelerometer (LLC, Pensacola, Florida) in predicting Energy Expenditure (EE) during walking.

The study was approved by the University of Limerick Research Ethics Committee, and volunteers completed informed consent documents prior to participation. Seventeen females aged 23 (SD 2) yrs walked for 7 minutes at each of 5 speeds (3.2, 4.8, 5.6, 6.4 and 7 km per hour) on a treadmill whilst simultaneously wearing the ActivPAL and the Actigraph accelerometers. Oxygen consumption and other variables were recorded for the last 2 minutes at each walking speed by expired gas analysis. Step counts were recorded every 15 seconds by the accelerometers and also by analysis of video recordings. Additionally, accelerometer counts were sampled by both accelerometers for each 15 second epoch. Step count agreement r-value between ActivPAL and Actigraph was 0.954. Correlations between ActivPAL steps and Actigraph steps with manual steps count were 0.988 and 0.953 respectively. When comparing energy expenditure (kilojoules per minute) with the two accelerometer step counts, the agreement was 0.594 and 0.552 for the ActivPAL and Actigraph respectively. Adjusting the energy expenditure for body weight increased the agreement to 0.632 and 0.581 for the ActivPAL and Actigraph respectively. On comparing metabolic equivalent to step count of the two accelerometers, correlations of 0.543 and 0.528 for the ActivPAL and Actigraph respectively were seen. Comparing heart rate at each speed to step count revealed correlations of 0.727 and 0.685 for the ActivPAL and the Actigraph respectively. However, accelerometer counts correlated more closely with EE.

Both accelerometers accurately measured step count, though the Actigraph tended to underestimate counts at low speeds. Relatively low correlations between accelerometer and measured EE indicate that accelerometer can at best only approximate EE with the ActivPAL outperforming the Actigraph in all analyses. However, raw acceleration data may provide a better predictor of EE since it is more sensitive to small changes in intensity.

CLIMACTERIC SYMPTOMS, OBESITY AND SARCOPENIA IN POSTMENOPAUSAL WOMEN

Coelho, E., Moreira, H., Almeida, V., Vasconcelos-Raposo, J., Freitas, J.
University of Trás-os-Montes and Alto Douro, Portugal

The aim of this study was to investigate the effect of obesity and sarcopenia in climacteric symptoms in postmenopausal women. One hundred twenty eighth healthy postmenopausal women (ages, 41 to 77 yrs; BMI, 16 to 44 kg/m2; SMI, 24 to 41 %) participated in this investigation. Skeletal muscle mass (SMM) and weight (Wt) were evaluated by tetrapolar bioimpedance being the first expressed as skeletal muscle mass index (SMM = skeletal muscle mass/body mass × 100). The subjects were considered to have a normal SMI if their SMM was higher than– one standard deviation above the sex-specific mean for young adults (aged 18–39). The height (H) is measured in meters and based on the combination of sarcopenia and obesity subjects were further classified into three groups: nonobese/nonsarcopenic (n=42), obese/nonsarcopenic (n=71) and obese/sarcopenic (n=15). Greene Climacteric Scale was used to assess climacteric symptoms (psychological, somatic, vasomotor, loss of sexual interest and total of these symptoms). The nonparametric tests Kruskal-Wallis and Mann-Whitney, with Bonferroni correction, were employed to compare groups.
